Breeding and Management of Geese (*J. T. L.*).—To give all the information you ask would require a long article, but the following extract from the "Poultry-keepers' Manual" is an answer to most of your questions:—"For breeding, not more than three Geese to one gander must be kept, and their breeding powers continue undiminished until more than twenty years old. They require a wide range, affording plenty of grass, and still water. The Goose house for the four should not be less than 8 feet long by 6 feet wide, and high enough for a man to stand in upright. A smooth floor of brick and good ventilation are necessary. Over the floor a little clean straw should be spread every second day, after removing that previously used, and washing down the floor. A compartment about 2½ feet square should be assigned to each Goose for laying and sitting, and when one is hatching, the gander and other Geese must be shut out from her. Wherever a Goose lays her first egg she is very pertinacious in there depositing the remainder. The Toulouse Goose is a very good layer, but rarely requires to sit, and, if she does, is a very bad mother. Where laying Geese are kept together, and they are liable to interrupt each other, remove the eggs daily, and mark on each the day it was laid. They will continue good for three weeks; but the freshest eggs should be set upon. If the Geese keep well to their separate nests, let the eggs remain. March and early in April is the best period for goslings to be hatched in. In February, or early in March, therefore, the Geese should commence sitting; for the period of incubation is from thirty to thirty-five days. Goslings hatched after April and at any time in summer, are reared with great difficulty. Thirteen eggs are quite enough for the largest Goose to sit upon. Food and water should be placed close to her, for she sits very closely. It is best for her to come from her nest daily, and take a bath in some neighbouring pond. The moisture of her breast feathers evidently is favourable to the eggs hatching, so that when they are placed under a common hen, or other domestic fowl, these eggs should be sprinkled with water every second day. When hatching has commenced, do not in any way interfere, for more harm results than benefit; both Goose and goslings are strong enough to take care of themselves. On the second day after hatching put a turf before the goslings; and a little boiled oatmeal, boiled rice, bread crumbs, and pond water are their best supplies for the first week. Put the water into a shallow dish, with means for them to get in and out easily. When a fortnight old they can shift for themselves, if allowed to go abroad with their mother, and not until then must they be allowed to frequent the pond. They require extra feeding, however, and this may be the same as given to other fowls. The only dangers they require to be sheltered from are heavy rains and a damp floor. During five days of the first fortnight the Goose may be put under a crate or large coop on grass. When put up for fattening, from six to ten thrive better than if only two or three are confined for the purpose. For the first fortnight give them oats and water mixed together, and afterwards barleymeal made of a crumbling consistency with water. They should be in a dark house, and kept quite quiet. They should be allowed to bathe in a pond for a few hours before being killed. They are then plucked more easily, and the feathers are more serviceable." Correspondents should be reasonable in their requests, especially when they send their questions at the last moment.

Names of Doves (*H. E. Kelsey*).—It is not easy to decide accurately upon the names of birds unseen and only described by words, as people differ as to their views and names of colours. We rather expect that the cock bird is a Stock Dove (Columba Œnas). The one described as the hen is, we fancy, a Turtle Dove (Columba Turtur). We have recently seen both birds in an aviary, and in perfect health. The Turtle Dove being a bird of passage, will show much uneasiness, and a desire to escape as autumn advances.

What are Rosewinds? (*Inquirer*).—If your question refers to a bird, we are not aware of any called by that name. There is an Australian Parrot or Parakeet called the Bloodwing. Rosewing may probably be only a local appellation.

Dandepratt (*Query*).—In Yorkshire the Bantam is so called; but we think it is a fond name for other small things.

Food for a Flycatcher (*Buz*).—It will eat any kind of soft food, such as boiled rice, boiled potato, a little hard-boiled egg chopped fine, with bruised hempseed and soaked bread added, scraped meat, small mealworms, or garden worms, and insects of any description. We do not think that there is much chance of your being able to keep the bird through the winter on account of its migratory habits.

Keeping Honey (*Amateur*).—If your cellar be perfectly dry, there can be no better place.

POULTRY MARKET.—September 1.

The hot weather has made quotations difficult. Senders were wearied with spoiling, and discontinued a small supply; an increase in price was the result.

From observations taken near London during the last forty-two years, the average day temperature of the week is 68.4°; and its night temperatnre 45.9°. The greatest heat was 88°, on the 13th, 1865; and the lowest cold 28°, on the 11th and 12th, 1860. The greatest fall of rain was 1.27 inch.

THE GLADIOLUS.—No. 1.

FONTAINEBLEAU.

EVER since my first acquaintance with the Gladiolus, an acquaintance now of many years' standing, it has been my desire to see them in their fulness of beauty at the place whence they had come forth year after year to win their way to favour and acceptance. Some years ago I was enabled to make the acquaintance of Monsieur Souchet, the raiser of these flowers, known not only as an enthusiastic and persevering florist, but as one of the most genial and hospitable men that France (or England, indeed), contains. No one has ever been to Fontainebleau to visit the Gladiolus, who has not felt that in M. Souchet and his admirable wife he has met kind and attentive friends, and have, like myself, regretted that the state of M. Souchet's health prohibits our having the gratification of returning the hospitality he so freely renders. I had not, although seeing and knowing the raiser, ever seen the flowers in bloom; my visits to Paris depended not on my own arrangements, but on the plans of others, and it was generally either in May or June that they were paid, and hence I never saw the Gladiolus in bloom. I had seen them growing, had pictured to myself what a wondrous sight it must be when these long beds were in their full blaze of beauty; when acre after acre was resplendent in their varied hues. Well, at last my wish has been gratified. I had not the usual business to take me there this year, and so determined to make a short visit. Mentioning my intention to the Editors of "our Journal," I was commissioned by them to undertake another work, about which I hope to have somewhat to say by-and-by, and at last have had the pleasure I so long anticipated. Like all our pleasures here, it has had somewhat of alloy in it, and I sometimes, as I think over it, almost wish I had not been there, not that I was disappointed, far from that, but I saw *too much*. How, I will presently explain.

With that consideration which my good friend always shows to everybody with whom he has to do, M. Souchet fixed the day of my visit, for what he called his "*jour de baptême*," the christening and arranging in order of merit the flowers which are to be sent out this autumn; and he, therefore, had about three hundred blooms cut and arranged in his house ready for inspection. These included the seedlings for selection and some of the flowers of this season for the sake of comparison, also some of those which are coming on, but are not yet multiplied. And here it is that I saw too much; not only were there flowers which are about to be sent out, but others in advance even of these. Now, when I look on my own flowers, beautiful though they may be, there float before my eyes visions not only of those I shall soon see, and perhaps possess; but then I think to myself, What are these in tint in comparison with those yet to come? I look at Virgile or Monsieur Legouvé, but then I think of one I saw and measured—5¾ inches by 5—and how poor in comparison, though really beautiful, are those flowers; and as one grower or another shows me some seedling he thinks highly of—pretty rough it may be—can I refrain from saying, "Ah! my friend, by the time you have a stock of this the flowers you think so much of will be among the things of the past." Yes, I give up *in toto* the idea of raising seedlings. One must be behindhand in the race. Who ever neared even Hoyle and Foster in the Pelargonium race? who ever could rush past my friend Mr. Banks in Fuchsias? No, the thing is hopeless; at least this was the impression made by my visit to Fontainebleau.

If anyone can act conscientiously in the matter of sending out his productions, M. Souchet must surely do so. He grows and selects those which he considers worthy of being sent forth into the world, but he does not arrange their order of merit. M. Ramey, from Vilmorin, Andrieux, & Co., M. Charles Verdier and M. Maillot criticise and examine, and by their report he is guided. He has three or four series, regulated by quality, which again regulates their price; these gentlemen determine which place the several seedlings shall occupy; and hence it sometimes happens that flowers of real merit may be put in a lower series, and yet be ultimately equal to their more favoured brethren. I would instance Moliere last year, which was placed in the second series, but which, I think, most of us prefer to Semiramis, beautiful though it was when I saw it at Fontainebleau; the day I was there, the last act of criticism was made by M. Ramey, and the names affixed to them. Of these I shall have something to say by-and-by.

The increase of the town of Fontainebleau and other reasons have rendered a change in M. Souchet's plans necessary; he has not so much ground at Fontainebleau as he used to have, and grows there only the newer kinds and the seedlings, especially those under trial; the great bulk of the older kinds with which he supplies the Parisian fairs are grown at Montereau, about three leagues off, where the soil is favourable, and the *ver blanc* [the larva of the cockchafer], less destructive than it is in the immediate neighbourhood of the forest. There can be little doubt that one great cause of M. Souchet's success is the fallowing of his land, which takes place two years out of every three; weeds, of course, are not allowed to grow, and hence the bulbs have the advantage of a fresh soil; but even with all his skill and experience he cannot banish the "chlorosis," which so often attacks the plants. He does not attempt to cure it, the moment a plant is attacked, "arrache" is the word; the spike may be in bloom, but he says the bulb is dead. It might sound presumptuous to question such an authority, but I am inclined to do so. Of course where they are grown by the acre, and where it is absolutely necessary that only sound bulbs should be sent out, such a procedure may be necessary, but it is manifest that we who grow a few cannot afford to do this, and I have evidence from my own garden that such bulbs are recoverable. When I was at Deal in the autumn of 1867, a number of my bulbs were badly affected, so much that I did not think it worth while to harvest them; I therefore at once planted them round one of my borders. When I left Deal in the spring of last year these were left behind, and only the other day, when revisiting my old place of

sojourn, I saw these bulbs with vigorous shoots and spikes of bloom.

The plan adopted by M. Souchet with the young bulblets or spawn is to place them, when taken off, in dry sand, and leave them thus until the spring. The sand is then gradually moistened until the outer coat begins to soften, and they are then planted or sown in rows, almost like Onions in drills. Where the time and space can be given to them, it is better to place them in pots first, and then to plant them out afterwards. But in truth, in the matter of cultivation, I do not think that we are much behindhand, and am inclined to fancy that, taking the same varieties, Mr. Kelway could exhibit as good a stand as M. Souchet. One thing I remarked, that a larger number of blooms were on the truss, generally speaking, than with us, but this, I think, is to be attributed in part to the warmer climate; for I notice even here that in sunny weather one gets longer spikes in bloom than when the weather is cloudy and cold.

I shall have more to say of the Gladiolus at home next week.—D., *Deal.*

STOCKS FOR FRUIT TREES—THE PORTUGAL AND ANGERS QUINCES.

It is really an act of kindness in Mr. J. Scott (see page 165) to give one an opportunity of going into—"ventilating"—this trifling subject, and it is much to be regretted that he has for so many years laboured under a mistake as to these kinds of Quinces, for it seems almost probable that he has neither one nor the other true to name, by which he must have been a great loser; still, it may be only his climate that has changed the nature of the Angers Quince. It was about the year 1831, that on reading Mr. R. Thompson's remarks on the Portugal Quince in the "Catalogue" of the Horticultural Society, and especially his recommendation of it as a stock fit for the Pear, that I was induced to procure some grafts of the sort from the garden at Chiswick. This variety proved larger than the common Quince, and a free grower; but, as I soon learnt from a Lisbon friend, it was not the true sort. This I soon procured from some source, and have now for many years grown it as the only kind of Quince worthy of cultivation for its fruit. It is not unfavourable as a stock for the Pear, but, at least here, it does not form so good a stock as the Angers Quince, nor can it ever be used to any great extent, for it does not strike freely from cuttings, but must be propagated by budding or layering. This quality tells against its use, for a hundred thousand Angers Quince stocks could be raised in the period required to raise one thousand Portugal Quinces.

With respect to the Angers Quince not being hardy with Mr. Scott, it may be operated upon by the warm nursing nature of the Somersetshire climate making it almost an evergreen; here, in our cold, dry air, it is as hardy as the Oak, and never suffers from frost or wet. In France it is employed as a stock for the Pear to a very large extent.

As Mr. Scott may not know its history, it will, I hope, be grateful to him if I narrate it. Some time between 1830 and 1835 I visited Angers, and in the Route de Paris, near the town, I observed a large nursery, called "Le Grand Jardin." Soon after my arrival I made my way to it, and was much gratified at its extent and with its venerable proprietor, uncle to the present M. André Leroy; he was a grand old gentleman, full of intelligence. Among the subjects we discussed was that of Quince stocks, as I wished to learn which he considered the best. I forget now what passed, but it ended in his sending me three or four sorts of Quinces, one of which was the Cognassier d'Angers, or Angers Quince. In a short time I found this variety more succulent than the Quince stocks I had received from Paris, swelling with the graft, and making the healthiest trees. From that period to the present I have never deviated from this opinion, and from the single tree sent to me by M. Leroy I have propagated hundreds of thousands, which have been widely dispersed in America and elsewhere. With skill it can be propagated by cuttings, but these require careful cultivation. One hundred thousand per annum are grown here. There is another variety of Quince, approaching the Angers in vigour, with leaves more glossy, but its tissues harder; this is the Doué Quince. After propagating it for some years, it has given way to the Angers, which is to a certainty the best of all.

The leaves of the four sorts of Quinces measure as follows:—The Portugal Quince, 3 to 3¼ inches in width; the Angers and Doué Quinces, 2 inches; the Paris Quince, 1¼. The Portugal Quince is remarkable for the thick coat of light fawn-coloured down on the under surface of its leaves. It is the most free-bearing of all, and if planted against a south wall, gives superb fruit. Pears budded on it do well enough, but not better than those budded on the Angers Quince. The last batch budded on this stock, some fifteen years since, did not make such vigorous, healthy trees as those budded alongside of them on the Angers Quince.

The Nain vert (Dwarf Green) Pear, mentioned in page 166, was raised from seed in France, and fruited for the first time about 1840. It is a great curiosity, for like the Dwarf Elm, Ulmus montana nana, it seldom or never makes shoots more than from 2 to 3 inches long in one season, even when grafted on a vigorous-growing Pear stock, like the Dwarf Elm when grafted on Ulmus montana. As with it, when double grafted, it does not dwarf the graft to any extent, but something like the Blenheim Pippin when double grafted on the Hawthornden Apple grafted on the Crab, it has some effect in moderating the habit of a vigorous-growing variety. It would seem that the tissue of these dwarf trees is changed when used as intermediate stocks. By a vigorous graft the cells are possibly ruptured by the suction of the graft, for if a common kind of Peach is budded on the Dwarf Orleans Peach, which rarely grows more than 3 inches in one season, the stock does not dwarf the sort budded on it, as do the surface-rooting Paradise and Quince stocks the Apple and the Pear, for both the dwarf Peach and dwarf Pear root deeply in the soil.

If seedlings are raised from the Nain vert Pear they adhere to a great extent to the habit of the parent; but, I repeat, owing to their rooting deeply, it is not probable they will form dwarfing stocks. To think of raising seedlings of Nain vert Pears, to graft with Pears for a commercial object, is a "*château en Espagne.*" My tree of Nain vert is some ten or twelve years old, is about 3 feet in height, is full of fair-sized green fruit, not bad, but not good.

To diverge from Quinces and Pears to the Apple, I may, perhaps, be allowed to mention that last spring I planted a border of a rather stiff, clayey soil with fifteen kinds of Paradise stocks, including the Doucin; for the most part a row of stocks and a row of Apple trees, grafted on the stock under observation. Four of these are Dutch stocks, imported last spring. One among them is the Creeping Paradise, mentioned by Miller. They are all of inferior quality, and the latter in particular is a pestilent thing, as it throws out suckers from its roots. Two kinds of English Paradise stocks, one from Mr. Waterer, of Knap Hill, and one from Mr. Pearson, seem nearly identical, and as good as stocks can be. Three are varieties of the French Paradise (Pommier de Paradis)—one from Doué on the Loire, which seems healthy, one from the neighbourhood of Paris, which, as has always been the case here, whether planted in light or stiff soils, has failed, all the stocks being leafless and cankered; still, I should note that some of the same batch of stocks, potted in light mould, have done well, the pots standing on the surface, but moulded up with cocoa fibre. These little trees, grafted in pots, make pretty bushes, but they are not more fertile than those grafted on the Nonesuch Paradise, for I have to-day seen a tree grafted on this stock, only 9 inches high, with three full-sized Apples on it, and hundreds of trees, from 12 to 15 inches in height, smothered with fruit. What more can we want? My third variety of Pommier de Paradis is one received from Mr. Scott. It has more vigour than the other two, and is the best of the three sorts. Last spring, when the stock mania was rife, I sent Mr. Scott some fine young Apple trees, grafted on my two kinds of Paradise stock, the Broad-leaved and the Nonesuch, begging his acceptance of them, and requesting him to send me in return two or three trees grafted on his kind of stock. I regret that, owing as I suppose to his being deeply immersed in business, he neither acknowledged my civil note, nor sent me the trees, and so I procured some through a friend, who ordered them and sent them to me.

With respect to the sale of Pears for double grafting in France, this is a comparatively modern practice. A member of the firm which sells them, worked here some years ago to learn our language and our ways. The trees offered are of all kinds, such as have not been sent out for orders. I bought some once, and *only once*—in truth, they are not worth carriage. Budding the Apricot on seedling Apricots requires skill and care. It is now many years since I saw a wall covered with Moorpark Apricot trees of my own budding; they were budded on seedling Apricots. Their aspect to me was very interesting, for instead of the strong plethoric habit of the same sort budded on the Plum stock, which the owner of the garden

told me disgusted him, by large branches dying almost every season, these trees had no gouty protuberances, but had slender healthy shoots. The owner of the gardens dying, and the place being far from home, I did not again see the trees. I only know that the Apricot stock is most difficult to manage.

My wish to make your readers acquainted with the nature of different kinds of Quince stocks, has led me into a stock discussion more lengthy than I intended. The subject is, however, full of interest, and many things are yet to be discovered relative to stocks. I can only say that my life has been, and still is, a life of experiment, and although I am aged, and sometimes inclined to think that another threescore-and-ten years should be added to my life to finish my tasks, the pleasure of experimental horticulture never flags, for, assisted as I am by a well-tried staff of employés, I can carry on my fancies with less fatigue than ever.—Thomas Rivers.

NOTES ON ROSES.

Most questions, including, of course, those arising from horticultural matters, have two sides, a *pro* and *contra*, and "D., *Deal's*," query why amateurs do not give their experience of Roses is by no means an exception. To write commonplace facts which every Rose-amateur knows, even if tolerated by the reader, must be an infliction on the Editors, and they have enough in that way. There is also a sort of egotism in putting into print what is going on in one's own garden when the information accorded is little else than trite truisms. These are some of the difficulties that beset a reply to "D., *Deal's*," invitation in his late article, "Among the Roses," yet I for one hope that it will meet with ample response. A rosarian can always find something to say about his favourites. He is always glad to read, if not to write, about them. He is pleased to meet with jottings of them, or even any one of them, whether they come from the antipodes, Loch Ness, Canada, or the North Pole. Roses at the North Pole! Why not? Ancient readers of "our Journal," as "Wiltshire Rector" has it, will remember very long ago that there appeared an article on "Gardening at the North Pole;" and where there is a garden, logically or illogically it follows there must be Roses.

In one of the papers read at the Manchester meeting, the writer stated his opinion that the strain of Remontants (the Hybrid Perpetuals) had "got into a rut." This is precisely the case. The seedlings are reproductions of the parents without any distinguishable improvement, and the selection is made with little discrimination in a floral point of view. One becomes tired of proving the worthlessness of the great majority of new Roses announced every season to tempt the unwary and disappoint the rosarian. We must therefore fall back upon our tried friends; they are yet numerous, most beautiful, and afford unfailing pleasure season after season to the careful cultivator. But even with them no true rosarian will be content to "rest and be thankful;" the process of selection may be carried much further. It is quite a probability that greater perfection is attainable both in the flowers and habits of kinds which are still far behind our standard of real or ideal excellence. Take, for example, light-coloured varieties, as Caroline de Sansal, Mdlle. Bonnaire, or even La Baronne de Rothschild; these are the best of the light kinds, but not one is equal to Charles Lefebvre or Senateur Vaisse in comparative merit. Take, again, dark varieties. Prince Camille de Rohan is still the best, but no one would compare it with the above-named two. Take, for a third instance, purple kinds, or kinds in which purple should predominate. There is yet scarcely one worth cultivating, and we keep Souvenir de Dr. Jamain, Gloire de Ducher, and one or two more only for the sake of their colour. If these desiderata can be supplied by selection only, there is still much to be done; but selection alone will not bring us out of that "rut" that we have been trundling along in lately. Were the French growers to take the full advantage of their better climate and turn their attention to crossing, they might be well assured that any important result would meet with its reward. The Remontants were obtained by artificial means, there is no evidence that these means are exhausted; there is, then, every reason to believe that new races, with new forms and new colours, may be brought into existence.

Till these things come to pass we may, therefore, be allowed to gossip about the Roses we have. The soil of this garden is of the lightest description, as it has been frequently stated in these columns. The situation is rather high, being about 425 feet above the sea level. The wind is troublesome at times, but there is a great advantage to balance it, which is the comparative freedom from or the harmlessness of spring frosts. Nearly all the Coniferæ thrive admirably, and many species are in vigorous growth that are scarcely ever met with except in similar situations. My Roses are on the Manetti stock, which I have adopted for several years. The Briar was a failure, and except for Gloire de Dijon, Céline Forestier, Maréchal Niel, Charles Lawson, Blairii No. 2, Coupe d'Hébé, and a few of the most vigorous Remontants, I have almost discontinued it. I adopt Mr. Radclyffe's dictum of giving my plants "plenty to eat and drink." Let our less experienced Rose friends pay attention to these few simple facts: Give the plants plenty to eat and drink; neither stint nor overdo it. Watch carefully for that safe medium that, when they are doing well, keep them so. Note the habit of growth of each variety, and regulate pruning accordingly, neither timidly leaving what ought to be cut away, nor barbarously mutilating healthy stems that yield good flowers. Cut off the dead flower-heads, especially after the first bloom is past, to one, two, or more joints, according to the strength of the shoot producing them; this will do much to insure succession of bloom. Pinch off in autumn the ends of long shoots that show no sign of bloom in the current season to develop buds lower down. Prune shorter in spring. Cut out as soon as discovered, and at any time of the year, all shoots that show signs of unsoundness, disease, or decay—they never recover. These are some of the more prominent points to be attended to in the cultivation of Manetti-stocked Roses. By carrying them out a succession of bloom, greater or less, may be obtained from May to December.

I intend to forward shortly a few notes on some of the Roses that I have in cultivation here.—Adolphus H. Kent.

It is always a pleasure to take a stroll with "the Dean," "among the Roses," even though it be in these pages, and not over the wonderful Hertfordshire soil; and as he invites the experiences of other amateur growers, it may be well that some of us should respond to the call.

This, on the whole, has been a cruel Rose year with us in the centre of Ireland. I walked in the end of June through the garden of a friend, distinguished for his Roses (he has, probably, somewhere about one thousand plants, or more), on the eve of a local show, and I doubt whether there were six blossoms in the entire garden which would have satisfied us any other season. I may say the same of most other gardens at the same time of year, though things improved very much after that. I myself am unfortunately circumstanced. My garden is about the most evil-minded one I ever came across. Before it came into my hands its life had been torn out of it by repeated doses of Potatoes without one atom of fresh material, except manure, ever compassionating its misery. It is too much confined by neighbouring hedges, and mildew and orange fungus run riot in it, and require incessant watching. Added to this, I am on the top of a cold, high plateau land. Any Rose that does well with me, will probably do well anywhere. I shall notice some of the Roses mentioned by "D., *Deal*," with any others I have, which seem to me to call for remark.

Paul Verdier bloomed splendidly; the blossoms were nearly 5 inches across, and opened freely. I am in despair at hearing "D." pronounce it not to be an autumnal bloomer. Mine, certainly, shows no signs of a second bloom. Charles Verdier, a lovely colour, would not open in July, though I gave it the copious drenchings of water ordered by Mr. Radclyffe. It is now giving a second series of blossom, opening quite freely, but is deficient in size. I have to state precisely the same of Sœur des Anges, Sombreuil, and Mdlle. Julie Daran. Joséphine Beauharnais has grown miserably, and has never opened at all; likewise Ville de St. Denis, Mrs. John Berners, Exposition de Brie, and King's Acre, except that the last-named is tolerably vigorous in growth. Mdlle. Annie Wood, though showing a centre, I confess, generally is, I think, a lovely Rose, and a most useful one; very vigorous, very free in blooming and opening, and a most enchanting colour when first expanded, very like a light Senateur Vaisse. Fisher Holmes is dull and ragged; Antoine Ducher very good indeed, though rather common in colour, small; Thorin, lovely in colour, something like Alfred Colomb, very large, and with me full; Monsieur Noman, very pretty in colour, sufficiently vigorous, but the blossoms spoil with me in the most provoking way. I never had a single blossom that did not look as if it had been taken out of a basket of wet moss. Black Prince, I think, is a very poor affair, very dull in colour, and not nearly double enough. It seems a

healthy grower. Jean Lambert is just the contrary, a beautiful blossom on a wretched grower. I have had it two years, and it never grows an inch.

Abel Grand is of a most beautiful colour, fine size, healthy habit, but no sign of autumnal bloom. Marie Baumann, very like Thorin, has dropped the leaves, and looks rather like a sick turkey. Princess Mary of Cambridge is a very abundant bloomer both in July and now, but the individual blossoms have not, I think, much to recommend them. Professor Koch did very badly with me last year against a wall, and I removed it to an open border, and cut it down very closely. I have been much pleased with it. It has been full and highly coloured, and is about to give a fine second bloom. Camille Bernardin has been most curiously different from what it was last year, when it bloomed miserably in summer and superbly in autumn; this year superbly in summer; but now it does not seem inclined to stir at all, though remarkably well fed. Marguerite de St. Amand is good in every way, I should say about the best Rose of its colour.

I cannot induce Cécile de Chabrillant, Madame Rivers, or Madame Vidot to succeed even moderately well. By Mr. Radclyffe's advice I moved them to a wall last autumn, but they are coy beauties, and I woo them in vain. Why is not Mdlle. Bonnaire more spoken of? It is exquisitely beautiful, and in places not subject to mildew, its enemy here, would, I think, be about the best blush white Rose we have. Maréchal Niel was covered with buds in spring. These were all nipped, with the exception of six, which opened well. It is now again covered with buds, and has one fine blossom expanded. At this time of year it seems to overcome the scragginess which distinguishes it in the earlier part of the season. From Climbing Devoniensis I cannot obtain a flower. It is on a south wall, and made shoots last year 10 feet long, which I expected to give blooming spurs this year; but no, nothing but mere sappy shoots and barren spurs. Triomphe de Rennes soils something like Monsieur Noman. Madame Fillion I think may go; small, ill-formed, and hard to open. Madame Margottin against a wall, and well treated, thrives badly; the blossoms fall off before opening, and the whole plant looks scraggy. Charles Rouillard has blossomed very abundantly and opened very freely, but I do not care for it; the lilac pink colour is poor, and the plant is terribly given to mildew.

But one forgets how fast the sheets multiply when on the subject of Roses. There are many Rose-growers in Ireland who could give us valuable information—for example, Mr. Nicholson and Mr. Coddington, of Oldbridge, whose Roses are simply superb; but they hail from a very different soil and climate from mine. As far as my experience goes there has been a want this season both in size and colour.—Q. Q.

I have been a grower for nine years, and have about three hundred varieties and six hundred plants, partly on the Briar, but chiefly on the Manetti. This is the sixth consecutive season in which I have had to contend with a long drought; this season has been the most severe trial of all, as we have had no rain to enter the ground since the end of the first week in May. The cold of that month and till the middle of June, showed its effects in black spot, stripping some varieties of their leaves. Géant des Batailles and its progeny I found most affected. After some very hot dry weather in the first week in July orange rust and mildew came on, and have continued their ravages more or less ever since. In spite of all, with mulching and thorough watering, I have had a fine show of bloom, though smaller than last year. My soil is the Devon red, where not manured and worked frequently, cracking very much. This season, after waiting three years, I have had some splendid blooms of Hippolyte Flandrin on its own roots, measuring 5 inches in diameter, beautifully imbricated, of a lovely rose colour, and superior in shape to Marguerite Dombrain, which has also bloomed well with me this season. Neither of them stood drought well. Charles Verdier and Antoine Ducher have both been good. Napoléon III. has proved a grand, brilliant flower, and continuous-blooming. The earlier blooms of Exposition de Brie were very fine in form and colour, the under side of the petals a fine bronzed purple. Sophie Coquerelle, a large light Rose, opens well, two or three blooms expanding freely at one time on a truss, and it has resisted mildew, &c., though close to Annie Wood most severely attacked. Acidalie has been very beautiful, throwing up shoots from 4 to 5 feet high, crowned with a boss of seven or eight perfectly-cupped, pure white flowers, slightly splashed with pink. Xavier Olibo has been very fine and strong in growth on the Manetti stock, and with me is decidedly the best dark Rose. Charles Wood is very strong, blooming finely at the terminals of new shoots from the root. It is kept constantly watered, is on the Manetti, and in very light stony soil. My blooms of Maréchal Niel against an east wall, where it bloomed well last year, were nearly all destroyed by the late frosts in June. It, as well as one on the Manetti, are now, particularly the latter, covered with buds, some nearly expanded. The latter was budded in 1867, and made a shoot 9 feet long last year, and is trained as a pillar Rose.

Buds of all Roses have succeeded well this year, I have only lost two out of 250. Narcisse expanded a fine bloom with eight buds just forty-two days after budding; several others are in bud. Devienne Lamy has opened this day (September 1st) from a bud of June 10th; a fine-formed rich crimson, somewhat like Senateur Vaisse, and it will be a very free bloomer.—Ide.

THE EARLY ROSE POTATO.

Having seen the account of the Early Rose Potatoes given by "A Subscriber," I also wish to say that I purchased 1 lb. of the above. "Subscriber" states he cut his into sixty-five pieces, and the produce was 44 lbs.; I cut mine into thirty-two sets, having one eye to each, all of which grew. I planted them, March 25th, about 4 inches deep, in a light soil, and when the tops were 6 or 8 inches high I moulded them. I dug up the crop on August 24th, and weighed them, having 48 lbs. produce from the 1 lb. Fifteen of the tubers average ¼ lb. each. It is a smooth, well-formed Potato, and not deep-eyed. When cooked, it is as good as I could wish.—A Worcestershire Subscriber.

I cut 2 lbs. into sixty-four sets, and planted them in ground of very moderate quality in the last week of April. Three sets did not grow, and five came up yellow and died off, so that I only had fifty-six good plants. All went on well until May 29th, when frost cut some to the ground, and some were only blackened. However, notwithstanding these mishaps, I took up 40 lbs. in the last week of July. There were about a dozen plants which the frost did not injure, and one-third of the produce was from these. Had the season been more favourable and the ground been in better heart, the produce would have much larger. I believe that it is a fine Potato.—R. Nash, *Seedsman, &c., Threchouscholds.*

I think "A Subscriber" has been very unfortunate with the Early American Rose Potato. I purchased 1 lb., consisting of two Potatoes; I cut these into forty-two sets, which I planted on the 25th of March at 2 feet apart each way; thirty-nine sets came up. I lifted the Potatoes on the 28th of August, and there were 105 lbs. 12 ozs. of Potatoes.—Arthur Wilkin, *Bootle.*

PLANTS LOSING THEIR VARIEGATION.

This season some of my plants of Polemonium cæruleum variegatum have reverted to the green state, not having a vestige of variegation. They were all propagated from the same stock. As the plant is so beautiful when in good condition, and so useful for bedding, it will be a matter of regret if this continue. Perhaps the season is the cause. Early in summer my plants of Dactylis glomerata variegata and Poa trivialis variegata were likewise quite green, and I was half inclined to discard them, but I cut them in closely, and as the new growth showed signs of variegation, I left them, and now they are all that can be desired. They have withstood the late hot dry weather well (we had on the morning of August 31st a white frost). Of the Aucuba-leaved Daisy many of the plants have lost all traces of their golden variegation, and some of them have died; they do best in a moist shady situation. Bambusa Fortunei does not answer well with us as a bedding plant, and is very undecided in its colour, sometimes being all white, sometimes green. Sedum sieboideum variegatum has in a great measure turned green, but if it would retain the variegated character it would be very desirable as a dwarf edging plant. Many plants of Arabis albida variegata have also become quite green, marring the effect intended to be produced. Hydrangea japonica variegata has likewise lost much of its variegation, and Philadelphus coronarius variegatus has in some instances become nearly green.

Other variegated plants have also shown a disposition to

become green-leaved, but what surprises me most is Pelargonium Bijou, some plants of which appear determined to become Tom Thumbs over again. I knew a gentleman who used to say he did not like those sickly-looking plants called variegated —the variegation was only the result of disease. I think them very useful and effective when they are what they ought to be. Mrs. Pollock Pelargonium has likewise changed from its usual character, and some of the plants would not be recognised as Mrs. Pollock. It would almost appear that variegated plants are a degenerating race, and when they assume an appearance different from that which they are expected to present, they destroy the effect they are intended to produce. The only remedy I can suggest is to discard those which do not exhibit a fixed character, and to select for propagation those in which the variegation is best defined.—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

THE INTERNATIONAL HORTICULTURAL EXHIBITION AT HAMBURG.

Hamburg, or Hamburgh as we are accustomed to call it in England, the very ancient, prosperous, free city, and general seaport for the whole of northern Germany, is just now holding high holiday with one of the most varied and extensive horticultural exhibitions that has yet been seen. This great Show, which was opened on Thursday last with all due formality, will continue until Saturday next.

As an exhibition of horticulture it is in many senses a great one. Far finer examples of cultivation we are accustomed to see in this country in almost every particular, but as a general exhibition of horticulture, embracing as it does almost every article connected with gardening—as a beautiful and a pleasing sight, for which no expense has been spared, it is certainly deserving of our highest praise, and unhesitatingly we say it is one of the greatest exhibitions that has come under our notice.

The promoters of this great Exhibition have had a most herculean task before them. The time they must have sacrificed, the trouble they have undergone, the great fatigue, and the immense expense involved, are little thought of now that it is all crowned by a triumphant success. We must congratulate them on the happy result. No little of the credit is due to the untiring exertions of its esteemed President, Syndic Dr. Merck, and its zealous Secretaries, Dr. Götze and Dr. Donenberg. The most unbounded praise is also due to the able designer of the beautiful grounds, Herr Jürgens, the architect, Dr. Halle, and M. Kramer.

The Jury, which numbered nearly two hundred, consisted of some of the leading horticulturists from all countries. It was presided over by the Burgomeister of Hamburg; this country being represented by the Rev. M. J. Berkeley, from the Government, Messrs. Harry J. Veitch, Thomas Osborn, Fulham, and A. F. Barron, Chiswick. The judging of the numerous classes occupied the greater part of three days. At the termination of their labours, the Jury, Committee, Town Councillors, &c., were entertained at a magnificent banquet. The beautiful Zoological Gardens were also thrown open to the Jurors, and a grand concert and illumination took place on Saturday evening. Horticultural Congress Meetings are also held every day, when discussions are held, and trips by steamboat to Blankenose, the beautiful suburb of Hamburg, on the Elbe. Everthing is conducted on a magnificent scale.

To give any adequate idea of the beauty of the situation, or of the labour that has been bestowed upon it to render it as it now appears, is quite impossible. It is on the north bank of the Elbe. Six months ago, or even less, it was an uncultivated valley, with steep rough banks on either side, and a dirty, weedy, piece of water at the bottom—a portion of the old moat which surrounded the city; now, under the hands of Herr Jürgens, the able landscape gardener, it has assumed a most fairy-like aspect. The ground is of a rather irregular oblong shape, one end of the valley opening on the river, and might measure over 20 acres, the other end is on the main street joining Altona and Hamburg. The situation and grounds are naturally beautiful, and the very excellent manner in which they have been laid out for the display of the different subjects render the grounds themselves quite an exhibition. The whole place has been remodelled, the piece of water much improved and enlarged. It lacks, however, gracefulness of form, and the steep banks on each side nicely moulded down are covered with a fine herbage, which is very remarkable considering that it was only sown about six weeks ago. It looks to the eye as if it had been so for years. The walks are judiciously planned, and the various groups of trees, shrubs, and flowers very well placed. To this are added some fancy bridges, islands, temples, pieces of rockwork, &c., here and there, and at the river end a graceful suspension bridge, 50 feet high, connecting the one side with the other. A pretty whole is produced.

On the level sides at the top on each side of this valley, are arranged in beds and groups in the open ground, such plants as Coniferæ, of which there are large exhibitions, Roses, Pelargoniums, Fuchsias, &c., and all such as are suited for the open air, and by this means the grounds are richly embellished with some of the choicest ornaments of the show. On each side are erected commodious, although not particularly handsome skeleton houses, covered with canvas, for the accommodation of all such plants, fruits, &c., as require it. On one side there is a large plant house, in which are exposed Palms, stove and fine-foliaged plants, and another large circular building for cut flowers and plants of smaller size. There is a great degree of roughness and darkness throughout these buildings, commodious and well adapted for their intended purposes as they may otherwise be. On the opposite side is, first, a large building devoted to vegetables, and another to what forms one of the most interesting portions of the entire exhibition, and in which the Germans seem far to excel us—viz., the exhibition of bouquets of dried flowers, for which every flower almost is used, most magnificent bouquet-holders, preserved fruits, wines, samples of seeds, &c.

Connected with this first piece of ground, quite enough for any ordinary show, is yet another portion of some acres. Access is had by a substantial wooden bridge across the street. Here are displayed the various pieces of machinery, garden implements, tree-transplanters, &c., and at the farther end about three-quarters of an acre devoted to the exhibition of specimens of the different modes of training fruit trees, a very important feature, and samples of general nursery stock. This portion is well displayed, and extremely interesting. The leaves having been all stripped from the trees, thus exhibiting but a lot of naked stems, give the place rather a wintry aspect.

Here, also, are two very long tents for the fruit-exhibitors. Apples and Pears occupy the greater space, an immense variety being exhibited. Grapes, however, are the grand feature, and these—the best examples, at least—come from our own country, and are shown by our champion growers, Thomson and Meredith, to the latter of whom the Queen's cup was awarded. Pine Apples are very good. It is impossible, however, to overlook the fact of the wretched and miserable appearance which the fruit in these tents, taken as a whole, presents; so much decayed and imperfect fruit has rarely been gathered together to greet the eyes at the opening of any exhibition.

Having now taken a rapid survey of the chief features of this great Show, we would, before proceeding to details, say a few words on the administration. Nothing, we are sure, could exceed the good intentions of its promoters and managers. We ourselves have had personal experience of this, and can truly say, that individually we have found them ever ready to assist us. It is with extreme reluctance, therefore, that we make the following remarks. In all great undertakings of this kind, in which so many interests are involved, a certain set of rules for guidance and management are established, which it is expected are to be equally binding on all parties, managers and exhibitors. Here, however, although the rules have been laid down clearly enough, we have been sorry to observe that in many cases they have been totally disregarded. A painful sense of shiftiness and vacillation is abundantly manifest. To be particular, all plants for exhibition in the open ground, implements, and machinery, had to be here not later than the 24th of August. Exhibitors from a distance complied with this rule, whilst some of those in the immediate neighbourhood were introducing their subjects up to the very day of opening.

Another serious ground of complaint is the cavalier way in which all exhibitors who have put themselves to very considerable expense have been treated. It is customary to grant passes of admission to exhibitors in accordance with their articles, and to a show which lasts twelve days like this it is abundantly necessary that exhibitors should be admitted. Not so at Hamburg, however. Every exhibitor, no matter what his contribution, or however much it may have added to the interest of the exhibition, has to pay for his admission, and that, too, at a high figure—about 18s. A strong protest signed by most of the exhibitors native and foreign was sent in to the Committee of Management against this rule: with no result, however. Representatives of the press, excepting those of

Hamburg, were allowed no privilege whatever. We cannot but think this extremely short-sighted policy of the Committee, which in the case of another exhibition being attempted will tell heavily against them. We are sure that English exhibitors, who are accustomed to such privileges, will know how to appreciate such treatment.

We now come to speak of a still more disagreeable subject, that in relation to the gold cup given by Her Majesty the Queen for Grapes. The exact definition of the words "For the best specimen Grapes" first communicated to England was somewhat difficult, so that the English committee applied to Hamburg, and received the information the cup was to be awarded "for the three best specimen Grapes," that signifying the best three bunches. In the German catalogue of the Exhibition it is, however, worded, "For the three best specimen Grapes in three varieties." On the simple understanding that it was offered for the best three bunches, Mr. Meredith entered and staged his fruit; and on the understanding that it was for the three bunches in three varieties Mr. Thomson entered and staged his. There was yet, however, another interpretation understood by Herr Wesselhoeft, of Altona, who staged his fruit as an assortment. To the intense astonishment of all the English exhibitors, it was then announced that a telegram had been received from Her Majesty that the cup was to be given "for the best assortment of Grapes," thus putting the English exhibitors at a complete nonplus. By chance, Mr. Meredith, having brought a collection of Grapes, was enabled to compete either for specimens or as an assortment, and thus he has the good fortune to bring back with him to England Her Majesty's cup. We cannot, however, too severely comment on the way in which this result has been brought about. The cup was distinctly offered for the best specimens of Grapes, and on this ground alone it should have been awarded. No alteration can by any fairness be allowed to take place, however exalted the donor may be. It is all very well to consult the wishes of Her Majesty as to its disposal. It was too late, however, to do so after the fruit was staged. We do not believe that if the matter had been properly represented to Her Majesty, that such an unjust proceeding would have been permitted. That the ultimate issue might not have been otherwise does not signify. A great injustice was perpetrated, especially to Mr. Thomson, whose exhibition was the only one strictly in accordance with the schedule, and his three bunches were, without doubt, the finest examples of cultivation. They had, however, the misfortune to be somewhat damaged in transit; Mr. Meredith's, on the contrary, arrived in splendid condition.

Beginning, now, with the plants in the large and principal building already alluded to, one end of which is principally filled with Palms and Ferns from temperate parts, and the other with natives of warmer climes, at the farther end we find the very splendid lot of new plants exhibited by Messrs. Veitch & Sons. These, although not entered for competition, form decidedly the finest group of plants in the whole Exhibition, and attract an immense amount of attention. They are so far superior to anything else here, that we believe, although they have not been entered, it is in contemplation to award them the gold medal for new plants. In the group are eight splendid plants of Nepenthes, that of Rafflesiana very large and fine; Hookeri; and the new hybrid between these two, one of the very finest, the pitchers very large; six of the new Dracænas, which are models of fine cultivation; the new Crotons; Japanese Amaranthus; hybrid Cypripediums; the new Dieffenbachia Bowmanni, a splendid kind; Lapageria alba, &c. Messrs. Linden, who compete, have here the next finest group, more numerous than Messrs. Veitch's, but not nearly so select. There are, however, some very fine plants, such as Palms, &c.; Dieffenbachia princeps, nobilis; Tillandsia Lindeni, a fine plant; the curious Cochlioslema Jacobianum; Fourcroya Lindeni, a fine plant, greatly resembling in appearance the variegated American Aloe; Cissus Lindeni, &c.

Of Orchids Messrs. Linden are the only contributors who stage a group of about twenty plants, amongst which we find fine plants of Acrides quinquevulnerum, Angulon Clowesii, Cattleya maxima, a large plant of the strange Trichotosia ferox, Odontoglossum Alexandræ Trianæi, the splendid Cattleya Eldorado, &c. The 500 thaler prize for the best group of fifty plants, one half of which must be in flower, has been awarded to M. Kramer, the very skilful gardener to Senator Jenich, Flottbeck, Holstein. The great mass of the plants in this group are of the most ordinary description. There are, however, a few splendid plants of Disa grandiflora, which tell well; they have from seven to eight stems from each pot, and each stem bearing from three to seven large and beautiful flowers. The cultivation of this fine cool terrestrial Orchid seems here to be perfectly understood.

A very beautiful collection of Anæctochils are exhibited also by M. Kramer, to which the first prize has been awarded. The specimens are small. The selection is, however, excellent.

Herr Wendland, Royal Gardens, Herrenhausen, carries off the first honours amongst Palms, of which tribe there is an immense variety exhibited. In Mr. Wendland's lot, the specimens of which are very large and fine, are the beautiful Geonomas Martiana, sarapigiensis, and Wildenovii; and Chamærops humilis bilaminata. Messrs. Linden, Brussels, have also some fine plants—Phœnicophorium Verschaffeltii, Areca Verschaffeltii and alba, Verschaffeltia splendida, &c. Fine plants of Cycas revoluta are contributed by Herr A. F. Reichers, Hamburg, which receive the first prize. This is a plant held in very high estimation in Germany. M. Jean Verschaffelt further exhibits some splendid Palms and a noble specimen of that beautiful tree Fern, Balantium antarcticum, with a stem about 10 feet in height.

We now pass to building No. 2, a very large oval structure, the interior being arranged with a sort of concentric circles and stages cone-fashion. Here are exhibited large groups of what are called market plants in lots of fifties or so, such as Azaleas, Camellias, Primulas, Heaths, and very fine Dracænas. The most of these are just ordinary stuff, such as may be seen in any nursery by the thousand.

Cut flowers of all descriptions and in immense variety are exhibited by Messrs. Ernst & Von Spreckelsen, seedsmen, Hamburg. These are staged so nicely, and so many of them together, that they really look well. Their double Zinnias, Asters, and Everlastings are very fine indeed. If we could only get such from their seeds, we should be satisfied.

Asters form a great feature of the Exhibition, an immense variety being exhibited from all the German seed-growers, F. Haage, Haage and Schmidt, Benary, Mohring of Arnstadt, &c. By far the finest lot, however, came from Dippe Brothers, seed-growers, Quedlenburg; these are really splendid.

Of Hollyhocks thirty-six varieties are shown by Messrs. Downie, Laird, & Laing, Stanstead Park, Forest Hill, and very fine they are, as also are their Pansies. A very pretty lot of Fancy Pansies, curious-looking things, come from Herr H. Wrede, Lunebnrg. These German Fancy Pansies take our taste more than the English strain; they are some of them so very singular in appearance. Cut Roses are well shown by Friedrich Harms, nurseryman, Hamburg. Dahlias and Gladiolus are here also shown, but none of particular merit.

An extremely interesting and extensive variety of Oaks, Elms, &c., small plants in pots, are exhibited from Moscow.

Tricolor Pelargoniums are exhibited by Messrs. Carter & Co., and Messrs. F. & A. Smith, Dulwich, whose plants are extremely fine and much admired. Bronze varieties come from Messrs. Carter and Messrs. Downie, Laird, & Laing, and a glass case of leaves of the same from Messrs. E. G. Henderson & Sons. Some of these leaves are so very vividly coloured that the visitors do not believe them to be genuine. Coleuses are abundantly displayed in variety. They do not look well, however, in this dark tent. The best come from Messrs. Carter & Co. One large plant grafted with twenty-eight varieties attracts a good deal of attention.

Passing now to the open ground, where the most of the plants suitable for the open air are exhibited, we find them placed here and there in groups or singly, according to their character. The placing and arrangement of all these plants must have been a task of considerable difficulty. We are bound to admit that it has been ably executed, and a most beautiful effect produced. It is a very excellent method of exhibiting such plants as Conifers, Roses in summer, Oranges, &c. They tell to greater advantage when placed thus in a natural position.

Conifers are largely shown, and form a grand feature in the grounds They are principally contributed by Messrs. Peter Smith & Co., nurserymen, Hamburg; Jurgens, Nienstadten; and Barron & Sons, Borrowash, Derby. The first prize for the group of 100 distinct varieties has been awarded to Messrs. Peter Smith & Co. There are some good varieties in this lot, but a great number are very coarse and inferior, and we question very much if there are 100 varieties. There were at least two Thuja Warreana which came under our own notice. M. Van Geert, Belgium, exhibits a very pretty lot of 100 smallish plants, which were awarded the third prize. In the class for twenty-five Abies and Picea the first prize was deservedly awarded to Messrs. Barron & Sons for a very choice collection, the plants about 3 feet in height, all pretty specimens. Messrs. Barron are again first for six distinct Retinosporas—viz., R. obtusa, obtusa nana aurea, plumosa aurea, plumosa alba variegata, pisifera, and lycopodioides. Second prize, M. J. Verschaffelt. The first-prize Wellingtonia, a plant about 10 feet high, from Borkoop, Holland, is a very wretched object, one-sided, and almost dead. Herr Jurgens carries off the honours for the specimen Abies lasiocarpa. Messrs. Barron's plant having lost its leader thus lost the prize. The first-prize group of Cupressus Lawsoniana comes from Borkoop, Holland, and is a very good lot indeed. In this class there is strong competition. Cedrus Deodara is well shewn, the first prize going to Jurriessen & Sons. Messrs. Barron's plant, although smaller, is in every respect a finer specimen, the leading shoot of the prize plant being very poor. Some fine Thuja Lobbi, Warreana, &c., are exhibited. Messrs. Peter Smith & Co. obtain the first prize for Abies Nordmanniana with a beautiful plant about 5 or 6 feet high. We cannot, however, say so much for the prize plant of Abies nobilis shown by Messrs. Peter Smith & Co. It is a small plant quite out of health, without a leader, but bearing some four or five cones, which we suppose must in the opinion of the Jurors have been a wonderful phenomenon. Messrs. Barron's plant opposed to this is twice the size and in most excellent health. Judgments of this

sort are perfectly ridiculous. The first-prize Araucaria imbricata from M. Jean Verschaffelt is a very beautiful specimen, from 10 to 12 feet in height. Little need be said of the other kinds of Araucaria—excelsa, Cunninghamii, Cookii, &c., except that they are very ordinary plants. Messrs. Barron carry off the first honours for Thujopsis dolabrata with very fine plants. No notice, however, seems to have been taken of the new varieties of Abies Douglasii exhibited by Messrs. Barron, which have received numerous first-class certificates in England. In Conifers the competition was more spirited than in any other section. We cannot, however, say much for the justice of the awards in many instances, or the judgment of the Judges. Favouritism seems to have been strongly present.

A very fine group of fifty varieties of Hollies are contributed by Messrs. Krelage & Sons, Haarlem, Holland. Standard Roses are largely shown, and in good condition in numerous groups by Herr Harms, nurseryman, Hamburg. A great quantity of standard Bay trees, and Oranges and Pomegranates in tubs are also shown, which look well arranged in lines along the walks. There is, however, nothing very remarkable amongst them. The Orange trees are as a rule rather inferior. Some pretty groups of standard Fuchsias are also shown by Herr Harms; the plants about 5 feet in height, with good heads of flowers in fine condition. The splendid way in which these were cultivated, although we hate standards, pleased us much. Ornamental trees and shrubs are contributed principally by Herr Jürgens, of Nienstadten, and amongst them are some fine specimens. They do not show, however, to much advantage.

Prizes were also offered for the finest groups of ornamental-foliaged plants. The prize lot, which is shown by A. F. Brockenberg, Hamburg, consists chiefly of Cannas, Ricinus, Dracænas, Wigandias, &c., the plants themselves are good enough, the arrangement, however—the effect produced—is not good. The same may be said of the competition for the best arranged flower beds. The designs are elaborate enough, yet there is no harmony, too much variety, and little taste. A few simple articles well used would have produced a better effect than anything here shown. We must just except some scroll leafwork in front of the plant house traced out and shaded off with coloured gravel and glass, and little dots of Sempervivum californicum and Echeveria secunda. That is extremely pretty and chaste. Some pretty patches of grottoes and rockwork are also displayed, which, however, it is altogether impossible to describe.

FRUIT.

The gold cup given by Her Majesty the Queen returns to England to grace the already bountifully bedecked tables of Mr. Meredith. Mr. Meredith exhibits for this honour several lots—1st, three very large, but rather ugly, bunches of Mrs. Pince's Black Muscat. They appear scarcely ripe, and are not fully coloured. 2ndly, three bunches of Frankenthal, which are magnificent. In his collection, besides these, are good examples of Black Hamburgh, Lady Downe's, Black Prince, Muscat Hamburgh, Trentham Black, Muscat of Alexandria, and Buckland Sweetwater, all very excellent examples of good cultivation. Mr. Thomson, of Dalkeith, competes with a stand of three remarkable bunches—Muscat of Alexandria, 5¾ lbs.; Chasselas Napoléon, 4 lbs., one of the best models of bunches we have ever seen; Black Hamburgh, 3½ lbs., scarcely up in colour. These, however, had the misfortune to be somewhat damaged (we believe after their arrival), which told against them. Judging them as three specimen bunches they are decidedly in advance of those of Mr. Meredith. This exhibition was awarded a gold medal. Herr Wesselhoeft, of Flottbeck, Holstein, exhibits a pretty stand, having the bunches suspended thereon. His specimens of Alicante, Black Hamburgh, Trebbiano, Raisin de Calabre, Muscat of Alexandria, &c., although very good, and displaying considerable merit, can in no way compare with the English competitors. They were awarded a cup given by the Duke of Mecklenburg, but upon what grounds it would be difficult to tell.

Mr. Thomson exhibits a small bunch of the new Golden Champion, which very deservedly was awarded a gold medal as a new variety. It is amusing to observe with what astonishment these English Grapes are viewed by the visitors to the Show, mixed as it is with a considerable amount of jealousy.

For the three best Black Grapes, Mr. Meredith, who competed, was disqualified on account of having been awarded the cup, and the first prize, therefore, went to Herr Heimendinger, a fruiterer in Hamburg. In the class, however, for the best White Grapes, Mr. Meredith has been awarded the first prize, although his exhibitions here are open to exactly the same objection as in the former.

From the gardens of the Duke of Angustenburg, Flottbeck, Holstein, come a good assortment of Grapes; the bunches are small, and many of them only half-ripe. A very pretty little lot of the small black wine Grapes, Château Lafitte, Château Larose, Château Gascours, &c., are also shown, but we cannot learn the exhibitor's name. From the Horticultural Society of Lower Tyrol, Austria, come upwards of seventy varieties of Grapes. These are under number, however, so that no names can be ascertained. There are some large bunches amongst them. Messrs. Demouilles, horticulteurs, Toulouse, France, exhibit a vast variety of fruits; eighty-four of Grapes, quite ripe, neatly packed in little boxes for export, as we see them in the shop windows. The various varieties of Chasselas have the prettiest and sweetest look. St. Antoine, a round black sort, looks well, as also Aramon, a sort much cultivated in the South of France. Diamant Traube, Marocain Noir, Muscat Romain, &c., all look very tempting. There are, besides these, a great number of other exhibitions of Grape, which, however, have no particular merit.

Pine Apples are well shown. The fruits, although none of them of enormous size, are all above the medium, beautifully swelled, and juicy. The varieties are chiefly Ripley Queen and Prickly Cayenne. The fruits, however, are of a much thicker and broader character than ours, not nearly so tapering. The prize lots of three cut fruit came from H. Fichtner, Breslau, and Oswald Hubner, of Breslau; the best fruit in pots from C. Delpeich, Luebau, Schleswig.

Peaches do not form a very interesting feature. M. Lepère fils, the great Peach-cultivator of Montreuil, however, sends some fair fruit—twenty-four varieties of Peaches, and six of Nectarines, the best amongst which are Reine des Vergers, Gain de Montreuil, Tardive Lepère, Grosse Mignonne, and Belle Beauce. A few good fruits of Stanwick Nectarine are also amongst them. This variety is named Standish's Nectarine. It seems to be nearly always wrongly named. The Peach crop on the Continent seems just to have been as great a failure as in this country.

Melons are largely shown, and amongst them some very splendid fruit. The first-prize lot of six came from Messrs. F. W. Frisenette & Sons, Nurserymen, Copenhagen, amongst which we find our own favourites, Beechwood and Bromham Hall. Herr Heimendinger, fruiterer, obtains a medal for a collection of North American and other Water Melons, which are to be found very frequently exposed for sale in the shop windows.

Fruit trees in pots are contributed largely and well. Apples, especially, are so well grown, the trees so healthy, the fruit so large and fine. Some examples of Calville Blanche are exceedingly large and beautiful, with a fine bright flush on their cheeks, that would make the mouth of a Rivers water to see them. The worthy President himself, Syndic Dr. Merck, shows his skill here. M. Wesselhoeft has also a fine lot. Senator Geddeffrey, of Holstein, and W. Schwab and Sons, nurserymen, Darmstadt, shew so well here, that it is difficult to say which is best. The Apple trees are for the most part small, not more than 2 feet in height, in 10-inch pots, and are bearing on an average from eight to twelve very fine fruit. The Pear trees are larger, and bearing some two dozen fruits each. The beauty of these trees is this—that every fruit is a marked specimen, and never do we recollect having seen them finer.

Messrs. Croux et Fils, horticulteurs, Avenay, Liz-Sceaux, Seine, France, exhibit an enormous collection of fruits of all sorts. Apples amount to 150 varieties, and amongst them are some most magnificent examples. The best was Ribston Pippin; Alexander; Wormsley Pippin, Ménagère, a fine large sort; Reinette du Canada, Calville Blanche, with a pretty rosy cheek; Lord Suffield, altered here, however, to Lady Suffield, Gooseberry, Pepin d'Or, like our Sturmer; Prince of Wales, a variety entirely new to us; Calville Impériale, a pretty, large, smooth, white sort; Cox's Pomona Sainte Barbe seemed to be our Mère de Ménage; and Beauty of Kent was named Herefordshire Pearmain. The collection of Pears consisted of 320 sorts, amongst which were some exceedingly beautiful specimens. We noted especially Beurré de Montgeron, a very beautiful, highly-coloured sort; Beurré Spence, which is evidently our Flemish Beauty—a Pear about which there always has been a lot of confusion, Thompson's, Glou Morçeau, Beurré Clairgeau, Beurré Bachelier, Duchesse d'Angoulême, Beurré Hardy, Louise Bonne, Senateur Reveil, a new and fine-looking sort; Madame Treyve, De Tongres, Doyenné du Comice, &c. M.M. Croux further exhibit fifty varieties of Grapes, thirty of Plums, Peaches, &c., amongst which, however, there is nothing at all worthy of notice.

Messrs. Jamain et Durand, nurserymen, Bourg-la-Reine, France, also stage an enormous variety of Apples, Pears, Plums, &c. The Apples and Pears are many of them exceedingly fine. Of the former, we may mention Reinette grise, Pomme Suisse, Calville Blanche, very large; Franketer Romaine, a very large, green, kitchen variety; Rivière, a handsome Pearmain-shaped fruit; Calville des Femmes, a very large green sort; Belle Dubois, our Gloria Mundi, &c. Of Pears, we noticed Draconon, a large sort in the way of Easter Beurré, Beurré Hardy, Louise Bonne of Jersey, Beurré Sterckmans, General Todtleben, a fine-looking Pear, and Joséphine de Malines. Knight's Monarch, Urbaniste, and Thompson's were here wrongly named.

Another very large collection of Apples and Pears came from Messrs. Martin Müller, nurserymen, of Strasbourg, France. Many of these consisted of our English varieties, the names of which were in very numerous instances misplaced and entirely wrong.

General Consul Ed. Ladé, Villa Manressas, Hesse, Prussia, exhibited a very fine collection of Apples and Pears, Grapes, Nuts, &c. Amongst the Apples we noted the following very fine—viz., Barchard's Reinette, Lelieur, a large pale sort; Hansmütterchen, a very handsome variety, in shape like Emperor Alexander, but quite distinct; Charlamowsky, pretty; Langton's Landergleichen, a very pretty medium-sized fruit. Amongst the Pears were good examples of Williams' Bon Chrétien, Doyénué Jamin, Doyenné du Comice, &c., and a dish of Bigarreau Mauresses Cherries, a very small hard sort of but little merit.

From the Horticultural Society, Bazen, Lower Tyrol, Austria, come a very magnificent assortment of Apples and Pears, which being under number however, and not named, could not be noticed. A good many fruits of the Maclura aurantiaca, or Osage Orange, are also in this lot.

Messrs. Demonilles, horticulteurs, Toulouse, exhibit seventy-eight varieties of Apples, amongst which were splendid specimens of Reinette

de Granville, Reinette de Caux, Reinette de Cassel, a large green sort; 180 sorts of Pears, amongst which the best are Williams's Bon Chrétien, very large and fine; Bon Chrétien de Vernois, a large, finely coloured, good-looking sort; Dureonot, like Gleu Morçeau, &c.; twenty-nine sorts of Figs, which, however, are very poor and scrubby, the only presentable sort being Neapolitan, a dark-skinned, oblate-shaped, medium-sized fruit; twelve varieties of Plums, and of this fruit it may be said that there is not a single good dish shown.

Very large collections of fruit, principally Apples and Pears, are also exhibited by the following gentlemen and scores of others:—Jacob Kern, Neussdorf, Landau; and L. V. Aichinger, Innsbruck, Tyrol, in whose collection are the following beautiful Apples—Bohmen, medium size, fine clear skin, scarlet flesh; Gramat; Maschanzger, pretty; Gestreifte Reinette. From the gardens of the King of Wurtemberg comes a collection in which are a prettily shaped form of Reinette du Canada Apple, and Rother Streipfen, resembling our Hoary Morning. Garten Inspector Wredo, Lüneburg, Hanover, has in his collection some of the most beautifully coloured Apples we have ever seen, especially one named Rosenappel bohmischer, of flattish form, angular, with a deep hollow eye and a clear transparent skin, nearly entirely covered with the most brilliant scarlet, as intense as in the flowers of a scarlet Pelargonium. Crameisenapfel is also very beautiful, and Marien Baumanns rother Winter, and Reinette Gostreifte Somer. M. Kramer, of Flottbeck, also stages a good collection, and many others, but their collections call for no particular notice; a very great portion of the remainder, indeed, being very much decayed and presenting a most unseemly appearance. It is utterly impossible to tell how the prizes have been awarded in many of these classes, or whether the fruits are really for competition or not. The whole system of judging and arranging from beginning to end is so utterly different from our English systems that we confess our inability to understand it, or at all events to appreciate it. We manage these things better at home.

Our remarks on the trained fruit trees, machinery, implements, vegetables, bouquets, flower decorations, and other miscellaneous matters, will be given next week.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 7TH.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. Lane & Son, of Berkhampstead, sent a collection of six varieties of Nuts and Filberts, including Red and White Filbert, Cosford, Late Cob, Purple, and Frizzled. Mr. Lockie, gardener to F. W. Berger, Esq., Court Gardens, Great Marlow, sent a valuable collection of nineteen varieties of Apples, Pears, and Plums, grown on pot trees in an orchard house. They were in every case remarkably fine specimens. The Gansel's Bergamot, Fondante d'Automne, and Williams's Bon Chrétien, were quite ripe and delicious in flavour. The Coe's Golden Drop Plum, Transparent Gage, Magnum Bonum, and Pond's Seedling, were remarkably fine specimens. The collection, altogether, was so meritorious that the Committee awarded a special certificate.

Messrs. Rivers, of Sawbridgeworth, sent a collection of six dishes of Grapes, consisting of the Early Auvergne, Primavis, Eugenien, Early Saumur, Tokay, and Early Golden. A special certificate was awarded for the collection. Mr. William Paul, of Waltham Cross, sent an interesting collection of fourteen distinct sorts of early and mid-season Apples, to which a special certificate was awarded.

Mr. Richbell, gardener, Tadworth Court, Epsom, sent fruit of the Honeycomb Melon. It was a good, large, green-fleshed variety, but too far gone, and the flavour was inferior. Mr. P. Frost, gardener to G. M. Fortescue, Esq., Dropmore, sent a seedling Melon, which was also passed. Mr. Beach, of Kingswood Warren, Epsom, sent a fruit of Beach's Green-flesh, and this was of excellent quality, and in good condition. Mr. Beach also sent a Scarlet-fleshed variety, which was quite unripe. Mr. Lockie, of Court Gardens, Marlow, sent a seedling Melon raised between Golden Queen and Bailey's Green-flesh, which was inferior in flavour. Mr. Dancer, of Little Sutton, sent fruit of Warner's King, and Cox's Pomona, two fine large early Apples worthy of general cultivation.

Sir Watkin Williams Wynn, Bart., of Wynnstay, sent a very fine dish of the Winter Greening Apple, the crop of 1868. They were in fine condition. G. F. Wilson, Esq., of Gishurst Cottage, Weybridge Heath, sent a very fine dish of Louise Bonne of Jersey, grown on pot trees turned out in the open ground, the flavour of which was most excellent. Mr. Cadger, of Luton Hoo gardens, sent a seedling Melon, which was too far gone, and had begun to ferment.

There were numerous dishes of Potatoes, which were ordered to be cooked before any opinion was formed of them, and the report to be made at Chiswick this day.

FLORAL COMMITTEE.—Mr. Robinson, Wartington, sent cut specimens of a scarlet zonal Pelargonium, which could not be noticed without the plant; Mr. Tillery, gardener to the Duke of Portland, four seedling Gladioli quite out of condition. Mr. Backhouse, York, sent a very fine specimen of Odontoglossum Alexandræ. The plant had two fine spikes of flowers. A special certificate was awarded it. Mr. Dobson, gardener to F. W. Scott, Esq., sent a box of cut flowers of a seedling Pansy of great promise if the habit of the plant should prove to be like V. cornuta. The flower is much larger and of a deeper tint of colour. It must be seen growing to give any idea of its merits.

Mr. Eckford, gardener to the Earl of Radnor, sent a seedling hybrid Ivy-leaf Pelargonium, Lady Edith, of robust habit; the foliage marked with a well-defined zone; colour of the flowers purplish rose, with very fair-sized trnss. This is a movement in a right direction; these Ivy-leaved hybrids will be found most useful for decorative purposes. A first-class certificate was awarded. Mr. Eckford also sent a large collection of seedling Verbenas; one of them, Countess of Radnor, received a first-class certificate—pale lilac ground with darker-shaded centre, a very distinct and pretty flower. The other seedlings were many of them good, but not distinct from many others. Cut specimens of the hardy and ornamental Clerodendron fœtidum were also brought from the same gardens.

Mr. Williams, Holloway, was awarded a special certificate for a collection of Orchids, also a special certificate for a fine plant of Eucharis amazonica. Messrs. Downie, Laird, & Laing sent seedling hybrid Nosegay Pelargoniums, Lady Kirkland and Sunshine. From Messrs. E. G. Henderson came Caladium Prince of Wales and Princess of Wales, with white-veined foliage, marked with broader rosy bands, and two fine specimens of Rochea falcata, an old but very beautiful plant. Mr. Cooper, Reigate, exhibited a collection of new Euphorbias, which were awarded a special certificate; also a collection of named kinds, of great interest from their curious and varied forms.

Mr. Parsons, gardener to W. Blake, Esq., Danesbury Park, received first-class certificates for two very singular forms of Lastrea—Lastrea Filix-mas ramisissima, and a diminutive parsley-like form—L. Filix-mas parvula. Two more opposite forms of this Fern could not be well imagined. It is a question worth considering, whether these deformities really merit the high awards they so often meet with. Mr. Parsons also brought a very pretty Gloxinia, called Sylph, white ground with pale lavender spots. Mr. Frost, Dropmore, sent cut specimens of Passiflora cincinnata.

G. E. Blenkins, Esq., brought a well-grown specimen of Vallota purpurea; this plant was exhibited to show how easily it might be cultivated in a greenhouse in London, and without any particular care. The original bulb had been six years in the same pot without being shifted, and produced from its offsets five spikes of beautiful flowers. How this plant obtained the name of purpurea seems doubtful; there is nothing purple about it. Can any of our horticultural friends throw light on this subject? Although a very old favourite, few flowers ever excited more attention than this specimen; many were the inquiries made after the meeting as to its name, culture, &c.

Mr. Barker, Littlehampton, Sussex, sent a box of cut Petunia flowers of considerable merit; a special certificate was awarded them. Mr. Thornicroft, Floore, near Weedon, sent Caladium Schottii. Messrs. Lee, Hammersmith, sent seedling Rose Clemence Raoux, pale salmon, tipped with deep rose, a very highly-scented variety. It received a first-class certificate. A variety of Adiantum capillus-Veneris, from the same firm, also had a first-class certificate.

Mr. Green, gardener to W. W. Saunders, Esq., received a special certificate for a very curious group of plants, Orchids and others. One Orchid of a very singular form and of great beauty was recommended for notice as a botanical curiosity. It was thought worthy of the bronze medal—a distinction or mark of honour lately suggested by the Council to be conferred on certain new, distinct, and rare plants of botanical interest. The name of this curiosity was Restrepia antennifera. G. F. Wilson, Esq., brought cut specimens of Lilium speciosum, many of them highly coloured, varying in shade of colour, and proving themselves to be varieties of Lilium speciosum. W. Marshall, Esq., sent cut specimens of a variety of Cattleya Mossiæ, also two of Lælia elegans Marsballii and Lælia elegans variety.

Mr. Bull exhibited a small plant of the beautiful Lasiandra macrantha; a special certificate was awarded. We hope next year to see a well-grown specimen of this superb flowering plant.

Mr. Turner, Slough, received a first-class certificate for seedling Dahlias Toisson d'Or and Harvard, and a special certificate for a very fine collection of cut named flowers. Mr. Rawlings received a first-class certificate for Dahlia Aristides; Mr. Parker, Wingfield, a first-class certificate for Dahlia Queen of the Yellows; and Mr. Burgess, Chelsea, a first-class certificate for Dahlia William Lund.

A special certificate was awarded for a collection of Orchids from the Society's gardens, among them a new and uninteresting form of Cypripedium Reichenbachii. Mr. J. Cooper exhibited a specimen of Ipomæa Chambersii with variegated foliage.

Mr. Looker exhibited specimens of his patent earthenware propagating-boxes. These will be found useful by lady amateurs who have no convenience for striking cuttings, and may be placed in a sunny window, and will be equally available for raising seeds; they are very portable and not unsightly. A photograph of a Lilium auratum was received from Mr. Smith, gardener to James Bland, Esq., Quarry Bank, Atherton. This bulb produced 193 flowers on a single stem. The bulb was planted in 1865, thus showing how much the bulbs improve as they become older and established.

GENERAL MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. After the election of one new Fellow, the Rev. Joshua Dix, in reporting the awards of the Floral Committee, directed attention to Looker's propagating-boxes, which the Committee had highly approved of, especially for the use of amateurs in striking cuttings and raising seeds. The Committee had suggested it would be an improvement to make the boxes without bottoms instead of as at present. A pot-cleaner from Mr. Green, of Garforth, was considered to require a greater

expenditure of labour than the present system. Some coloured drawings of plants and leaves from Mr. Macfarlane, of Upper Holloway, were noticed as being praiseworthy, and a photograph of a remarkably fine plant of Lilium auratum was pointed out. This plant, it was stated, had produced 193 flowers between August 4th and September 6th, as many as sixty-five being expanded at one time. The Chairman of the Fruit Committee, Mr. Wilson, mentioned as a fact, the knowledge of which might be useful now that persons are staining their fingers in picking Mulberries, that the juice of the berries in the red stage takes away the purple stain of the ripe ones.

Mr. Wilson Saunders remarked, in connection with Ivy-leaved Pelargonium Lady Edith, shown by Mr. Eckford, that it was very desirable to unite large bright-coloured flowers to the succulent glossy leaf and pendulous habit of the Ivy-leaved kinds; and he had no doubt, if the attempt were made, new and important varieties would be obtained. The fine specimen of Eucharis amazonica, from Mr. Williams, next claimed attention, and Mr. Saunders said there was no better plant than it for a moist hothouse, for if properly treated it is always in flower. A pot of Vallota purpurea, grown by G. E. Blenkins, Esq., in a London greenhouse, was next referred to as a successful instance of culture, and Mr. Saunders asked Mr. Blenkins what was the mode of culture pursued.

Mr. Blenkins said the bulbs, originally very small, were kept three years without the soil being changed; they had been once changed, three years ago, and had been six years in the same pot. The soil used consisted of one-third peat and two-thirds loam, with a little silver sand. His sole object in exhibiting the pot was to induce people to grow this bulb, and to show with how little trouble it could be done.

Mr. Saunders remarked that plants of the Vallota and other Amaryllids are very impatient of their roots being meddled with. The Rose Clemence Raoux was then noticed as having a most delicious perfume—a property in a Rose which florists of late years had too much neglected. For his own part, he did not see why the sense of smell should not be gratified as well as that of sight. After noticing Tritoma Uvaria as a very ornamental plant not so commonly grown as it ought to be, Mr. Saunders concluded by stating that the exhibition of Fungi would be held at the next meeting, on September 21st, or in October.

BOUQUETS AT THE MANCHESTER SHOW.

I took two bouquets for myself, and two for my son, to the Manchester Exhibition, and after the awards were made I found the first prize was awarded to me, and the second to my son. About two hours after the awards were made a friend was standing with me near the bouquets, when we found they were going to alter the awards, and one of the judges said, "No. 9 card is the prize card." Now, how did he know this, when there was no No. 9 card? for the first-prize card was No. 10, the second-prize card No. 8. As there was no No. 9 card, he said, "There is some mistake, we must go back." They did so, and came again, when I drew their attention to the rules for the guidance of exhibitors. He read them carefully, and then said, "We can do nothing in this matter, we must let the awards remain," and away they went. In half an hour they returned, exclaiming, "We must alter these awards," and they did so. I applied at the Secretary's office to protest against any alteration in the awards. I was told there was no protest allowed. Now, if there was no protest for me, whence did Mr. Yates get the privilege to protest? The schedule says the decision of the judges is final. If so, why do they revise their judgment? If mine had been the finest bouquet ever made, if I had omitted to place proper cards, there evidently would have been no appeal for me. The schedule says expressly exhibitors are responsible for the placing of cards, and as Mr. Yates did not put any cards to distinguish his bouquets, I maintain it was an act of injustice to alter the awards; in fact, the judges' decision is final, and they have no power to alter them.—W. H. Turner.

WHO IS TO BLAME?

Who is to blame for the misrepresentations of catalogues? To illustrate. Who has not seen the grand picture of Laxton's Supreme Pea, short-stemmed, closely-set, magnificent pods, revealing their fourteen fat Peas within, described to grow "about 3½ feet high?" but who has seen it anything like its description? Wishing to grow the best of everything, and revering the name of Laxton, and having the utmost confidence in my seedsmen, I invested in half a pint, at the moderate (?) cost of 3*s.* 6*d.*; these I planted in a row 24 yards long, to give them every chance. The result was straw 7 feet 7 inches high, instead of 3½ feet; instead of fourteen Peas in a pod, out of many hundreds counted I never once found ten; instead of a total growth of 3½ feet, they did not "corn" within 3½ feet, and generally 4 feet of the ground; they required twice sticking, and smothered their far more worthy neighbour, Veitch's Perfection, and, save in the shape of their pods, in no way resembled their description. The same complsint is made by other gardeners who have grown it in this neighbourhood.

Take one other instance: Lemaitre's [Lenormand's] short-stemmed (new), very fine Cauliflower, was sent out at 2*s.* 6*d.* per packet. I weighed the contents accurately, and found it cost at the rate of about £80 per lb. Surely it must be good; but with all the care in cultivation possible, it is no better than many old sorts. Who is to blame for these great disappointments? and who can wonder if gardeners manifest an increasing reluctance to be the first to risk a trial of the wonders of the catalogues?—C. C. E.

PLANTS FLOWERING IN AUGUST.

August 3. Funkia lanceæfolia
Gentiana Pneumonanthe lutea
Hedysarum coronarium
Hemerocallis flava graminea
Morina persica
Lychnis coronata
Phlomis Russelliana
Physalis Alkekengi
Potentilla reptans
Gaillardia picta Richardsoni
Geranium lanceastrienee
Linum perenne Lewisii
Sedum Aizoon album rupeatre
Statice bellidifolia latifolia
Tigridia pavonia

Santolina incana
Sanvitalia procumbens

—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

SUDDEN CHANGE OF TEMPERATURE.

What a season this has been for violent changes. On Friday, August 27th, the thermometer was 85° in the shade, on Saturday 86°, on Sunday evening 52°. On Monday morning my lawn was as white with frost as if it had been midwinter. Kidney

Beans, Potatoes, Vegetable Marrows in the kitchen garden are all black, and in the flower garden Scarlet Pelargoniums quite spoilt for the season. I hear that at Lord Brownlow's, near Grantham, even Broccoli is killed. I think the "oldest inhabitant" cannot remember a frost in August.—J. R. Pearson, *Chilwell, Notts.*

GARDENERS' EXAMINATIONS.

The following are the names of those who took certificates, and the number of marks obtained at the Royal Horticultural Society's examination of gardeners, July 13th. The names of Chiswick students are marked with an asterisk. James Hudson obtained the whole number of marks in Fruit and Vegetable Culture, being the first candidate who has done so.

Name.	Fruit and Vegetable Culture.		Floriculture.	
	Certificates.	No. of Marks	Certificates.	No. of Marks.
George Haskins*	3rd class	360	2nd class	625
Alfred Jones*	3rd class	530	3rd class	4 0

W. Read, Royal Gardens, Kew	3rd class	390	3rd class	425

CUCUMBER CULTURE.—No. 9.

Ridge and Hand-glass Culture.—At the beginning of May prepare some stable litter in the same manner as for hotbeds, and when this has acquired a good heat, and parted with its rankness, without becoming too much decayed, it is fit for ridge Cucumbers. Select an open situation, sheltered from the east and north winds by a wall or fence, and to the west as well, for the violent winds we frequently have from this quarter do great mischief to the leaves. For ridge crops I usually select the west end of a south border, as I find the plants succeed best in such a position.

Having chosen the best situation for warmth and shelter, take out trenches 15 or 18 inches deep, and from 2 feet to 2 feet 6 inches wide, allowing 6 feet between the outside of one trench to the outside of the other. Fill the trenches with well-fermented dung, making it 8 or 9 inches higher than the ground level, and cover with the soil to the depth of 8 inches, and in the form of a ridge. In the centre of each ridge, at every 3 feet, place a hand-glass — those which are square and have moveable tops are the best; there I draw off some of the soil, and replace it with 3 or 4 inches thick of light turfy loam two parts, and one part leaf mould, finally covering with about an inch deep of finely sifted soil of the above description. On the third or fourth day sow about a dozen seeds under each hand-glass, to make sure of four plants, none of the seeds being nearer the outside than 6 inches, the proper distance for all. The seeds are placed on the surface at equal distances, and pressed into the soil with the forefinger, and to the depth of the nail. The holes are then filled up, a gentle watering given, and the hand-glass tops put on, and kept close until the plants appear, which they will do in less than a week. The soil in the meantime is kept moist by gentle sprinklings with tepid water.

When the plants are up, a little air is given early in the day, by lifting the upper part of the glass, and placing it crosswise, varying the amount according to the weather, and closing early, so as to shut in the heat of the sun. The plants will have fine cotyledons and very short and thick stems, if enough air be given. If the stems are weak and long, the plants are kept too close and warm, and require more air. The rough leaves will be broad, and of a deep green; when they appear make choice of the best plants, pull up all but half a dozen, and take out their points at the second rough leaf; this is all the stopping that will be required. By the time the first rough leaf appears, I have the plants earthed-up to the seed leaves with the soil used for sowing in, choosing a fine warm day, and giving a gentle watering with tepid water. Care should be taken not to over-water, but the soil must be moist without being saturated.

When the plants have broken after being stopped, select four of the best, and these, if possible, corresponding to the angles of the lights or glass. The others are taken up carefully, to fill any vacancies in the other lights, or they may be planted-out and covered for a time with flower-pots. The plants are again earthed-up, removing the lights for the purpose; put the soil up to where the seed leaves had been, allowing it to extend somewhat beyond the lights, so as not to form too much of a ridge. The lights are replaced, and the plants have air and water as required.

As soon as the plants fill the glasses, and before they become crowded, the upper part of the glass is fixed, and the whole light raised on the warmest side, by a brick placed on the flat, or a 3-inch pot, for three or four days, and then 1 place under each corner a 4½-inch pot. Within a week I peg down or train the shoots from under the glass, distributing them equally all round. When they begin to run freely, I give air again by the upper part of the glasses, and by degrees withdraw this and the lower part; for if left on much longer, red spider will be encouraged on the foliage beneath the lights, and will rapidly spread. All the plants need after this, will be plentiful supplies of water in dry weather, and occasionally regulating the shoots. The ground between the ridges must be forked over as the plants advance, and be kept clear of weeds. It will be found advantageous to blacken the ground with soot, after stirring and making it even and fine with a fork.

It is usual to sow the seeds under glass, and rear the plants in frames; potting-off, and planting-out under hand-glasses after well hardening-off. Some sow in the beginning of April, or earlier, and the plants turned out at the end of April, or beginning of May, are strong at the time I advise the ridges to be made, and the seed sown. Those who prefer this method have only to plant instead of sow, when the heat in the ridges has come through, and the after-treatment is the same as above. I may, however, state that the best Cucumbers I have had out of doors were those sown from the 10th to the 13th of May, where the plants were to fruit. It is a practice which has been followed a century, if not more. By early sowing a few early and often worthless fruit are obtained, and the plants become stunted, and vanish very often in a day or night without apparent cause, not that those sown where they are to fruit are exempt from the same evil, but having a stronger constitution they are better able to contend with the sudden alternations of heat and cold, wetness and drought, to which they are subjected in our ever-variable climate.

Culture in the Open Ground.—The situation ought as far as possible to be similar to that described for the hand-glasses. The ground should be rich, and if light all the better, as light sandy soils, though drier, are warmer than heavy soils. The seeds should be sown from the middle to the end of May, and in the manner described for plants to be grown under hand-glasses. I make a hole at every 4 feet, beginning 2 feet from the end, and then allow 4 feet from centre to centre of the holes. These may be 1 foot deep, and 2 feet square. A barrow-load of hot dung is placed in each hole, and covered with from 4 to 6 inches of soil, which is made quite smooth, and surfaced with about an inch of fine soil. After marking the size of the hand-glass by placing it over the spot where the hot dung is, the seeds are placed over the space inside the hand-glass, at an inch apart, and pressed into the soil. The holes are then filled up, a gentle watering given, and the hand-glass put on. In a few days the plants will be up. A little air is given, but only enough to keep the plants from becoming drawn. When they show their rough leaves, a little fine soil should be placed round their stems to encourage the emission of roots, and when there are plenty of these the plants are more safely transplanted.

When the seedlings are in the rough leaf, and before the plants are earthed-up, every alternate plant should be thinned out. The plants taken out may be placed two or three in a pot, set in a cold frame, and kept close, shaded, and moist until established, and then be hardened-off, planting out after stopping at the third leaf; or, instead of potting, they may be planted out at once, making holes about 18 inches square and a foot deep, and filling these with hot dung, covered with 6 inches of soil. In the course of three or four days four plants may be pricked out on each station. A large pot inverted over the spot, when the soil is put on the dung, will retain the heat, so that the ground will be quite warm. The seedlings are planted as deep as the seed leaves, a gentle watering is given, and the pot inverted over them, leaving it close at night, but tilted a little on one side after the first day. By tilting more and more every day, it may be withdrawn altogether in a week or ten days; it should, however, be replaced in cold nights, and to shelter the plants from cold, heavy rains.

The plants under the hand-glass will have grown rapidly after the top-dressing, and will be as far advanced for planting

ont as those potted-off and grown in a cold frame. The ground where they are to be planted must be well forked over, and, if possible, at every 3 feet make a hole 18 inches square and a foot deep, and fill it with hot dung; after drawing the soil over it, each set of plants will stand on a slightly-raised mound, the top of which should be made flat. Three or four plants will be sufficient for each mound. Allow 6 inches from plant to plant every way. Give a gentle watering, and protect from sun and cold with an inverted flower-pot. Water will be required every second or third day, according to the heat or dryness of the weather. The distance between the rows may be 6 feet. Watering should take place in the evening, or early in the morning. No stopping will be required if the shoots be equally distributed over the surface. All but four plants may be taken from each hand-light. It usually takes a month from sowing until the plants are of a size fit to plant out. They will fruit in August and September.

Instead of sowing under hand-glasses and planting out afterwards, seed may be sown in pots, and the plants pricked off when large enough, sowing and forwarding them in a frame, and when they have three rough leaves they may be planted out where they are to fruit. The sorts most suitable for ridge culture are Stockwood Long Ridge, Bedfordshire Surprise, and Long Prickly; for open-ground crops the Long Prickly, and the Short Prickly for pickling.—G. Abbey.

THINNING MELONS.

Having on several occasions been unfortunate in Melon-growing, owing to the first-setting fruit having taken the lead, and appropriated all the nutriment to itself, I have this season experimented on one of my plants, by cutting off the fruit when it had attained a sufficient size to show me that it would deprive the others of a fair share of sap. This practice has proved a success; in fact, it has more than answered my expectations. The plant I selected for the experiment was Trentham Hybrid, which at the time of flowering produced eight female blossoms, all of which I fertilised, but I soon found that one of them was swelling much more quickly than the rest. I allowed it to attain the weight of 2lbs.; the others at this time were all turning yellow, and were not larger than a pigeon's egg. The result was, that every Melon on the plant began to swell rapidly, thus allowing me to choose whether I would allow them all to grow, or reduce them to my usual number, which is four to a plant, and by preferring the latter I have obtained some fine fruit.—W. Wrench, *Padnall Grove, near Chadwell Heath.*

[The plan you have adopted has been advocated by Mr. Fish and others, only we would not let a Melon grow to the weight of 2 lbs., and then cut it off, but would do so at a much earlier period. If one Melon sets and swells freely on a plant, later ones will not often swell whilst it remains; hence the importance of having the requisite number set, and commencing to swell at once.—Eds.]

DEATH OF MR. ROBERT THOMPSON.

It is our painful duty to announce the death of Mr. Robert Thompson, so long known and so highly esteemed as the Superintendent of the Fruit Department in the garden of the Royal Horticultural Society at Chiswick, author of the "Gardener's Assistant," and numerous other contributions to gardening literature. The sad event occurred on Tuesday last, the 7th of September, at 7 25 P.M. For a considerable time past Mr. Thompson has been gradually declining since suffering from a stroke of paralysis, with which he was attacked about two years ago; and although he was latterly incapacitated from doing anything either in the way of work or amusement, his intellect never failed him to the last.

From 1824 to the day of his death Mr. Thompson may be said to have been connected with the Horticultural Society, for although his active duties ceased only eighteen months ago, the Society, in recognition of his worth, retained him after affliction had incapacitated him from further service, and now, after a life of forty-four years of great activity, this kind-hearted amiable old man has gone to his rest. There are many who will read this record with feelings of regret. There are those, and they are now few, who began life with him; who shared with him as young men in those early days of Chiswick gardens, the pleasures and privileges attendant on the impetus then given to gardening, such as it had never before received—those days of Thomas Andrew Knight, Sabine, and Lindley. And there is the younger and far more numerous class who have sat at his feet, and have drunk-in instruction from his words and his writings. They, too, will regret him.

Mr. Thompson was born at Echt, in Aberdeenshire, early in September, 1798. The precise date of his birth is not known, as at that period the birth registers of Scotland were not preserved with that care with which they are now. But from his baptism having been on the 16th of October in the same year, we may reckon with some degree of certainty that this ceremony was performed, as it usually is in Scotland, a month or six weeks after birth. His father was a small farmer, and after he had received the solid education of his native parochial school, he was placed under his uncle, who was gardener to Mr. Skene, of Skene, where he was employed in the garden and plantations. He then removed to Haddo House, the seat of the Earl of Aberdeen, where he remained till 1820, and then left for the garden at Dunottar Castle, the residence of Lord Kennedy. After remaining there for one year, he removed in November, 1821, to the gardens of Robert Ferguson, Esq., of Raith, in Fifeshire, where he was for nearly three years.

In 1824 Mr. Thompson reached London, and went directly to the garden of the Horticultural Society, at Chiswick, to which he had been recommended by his late employer's brother, Sir R. Ferguson. The garden was then nearly completed; the collection of fruit trees had just been planted, some of them which were worked on Paradise stocks were coming into fruit; and the walls which enclose the orchard and kitchen garden had then been just finished. Mr. Thompson was at once placed in the fruit department, which was then superintended by a Mr. Christie, and no time could have been more opportune for his entering on his duties, as from the first he had under his observation the immense collection of fruits which then and subsequently has existed in the gardens. Early initiated by Mr. Knight and Mr. Sabine into a knowledge of the characters and merits of the then existing varieties, Mr. Thompson acquired a knowledge and taste for the study of fruits and fruit trees which increased with his years, and which he retained to the last. During the whole of the forty-four years of his active life at Chiswick, pomology was his special and passionate study, not only as it was exhibited under his eye in the garden, but in the literature and practice of the pursuit, as existing on the Continent. It was this well-grounded and thorough knowledge of the subject which enabled Mr. Thompson so well to produce that laborious work, the "Catalogue of Fruits cultivated in the Garden of the Horticultural Society of London," which has formed the foundation of modern pomological synonymy. No one, except such a person as Mr. Thompson, could have done this work so well. His proverbial patience and painstaking, his excessive care and caution, admirably fitted him for such a work, and stamp it with an authority which has never been assailed. It was not, however, in pomology alone that Mr. Thompson excelled. Every department of horticulture received from him its due share of attention; and not in the practice only, but also in the higher principles of the pursuit, did Mr. Thompson eminently shine. In physics, we believe we are doing none of his contemporaries an injustice when we say he excelled them all. His love of physical science was equalled only by his love of gardening; and his knowledge of mathematics was of a high order. No better evidence of the combination of these qualities can be given than that which is furnished in that admirable compendium of horticulture "The Gardener's Assistant." Meteorological science is much indebted to him for the constancy and correctness of the observations he conducted at Chiswick from 1830 till within a few months of his death; a period of thirty-nine years. And here we may take the opportunity of noticing a remark we sometimes have heard made by others who note meteorological observations. Doubts have been expressed as to the correctness of the instruments used at Chiswick. It has been said that the temperatures announced by Mr. Thompson were, when excessive, too high or too low, and that they did not correspond with those of other observers. It is, nevertheless, a striking fact that on an average of thirty years' observations—from 1826 to 1855—the difference in the records of mean temperature between Chiswick and Greenwich amounts only to 0.06°—a lasting tribute to the care with which the Chiswick meteorological observations were made.

Mr. Thompson was a voluminous writer, though he does not appear as the author of many works. In the "Transactions of the Horticultural Society," besides the bulky meteorological

tables, there are many valuable papers on horticultural subjects. To Loudon's "Gardener's Magazine," the *Gardeners' Chronicle*, the "Edinburgh Philosophical Magazine," and other periodical publications he was a frequent contributor. In the preparation of most of his great works, Mr. Loudon acknowledges the aid rendered by Mr. Thompson, and especially in the "Encyclopedia of Gardening," and the "Suburban Horticulturist." He contributed also to the "Penny Cyclopedia," Morton's "Cyclopedia of Agriculture," Maunder's "Treasury of Botany," and, we believe, he was the sole author of the letter-press of the "Pomological Magazine."

Towards the close of his career a tribute to the services he had rendered to horticulture was paid to Mr. Thompson, by the presentation of a testimonial, amounting to the sum of £400, raised by public subscription, and on the end of his active services in connection with the Royal Horticultural Society he retired on full pay.

We understand that the funeral will take place at Brompton Cemetery, on Saturday next.

NOTES AND GLEANINGS.

The Knight of Kerry writes with reference to the Beechwood Melon, noticed in page 169:—"Another Melon from the same frame and of the same kind was cut on August 28th, which, I am assured, weighed rather over 14 lbs. I was not present, but have just now seen it carefully weighed, and it reached 13 lbs. 10 ozs. The length of time that has elapsed since cutting will, I suppose, account for that reduction. My gardener is quite positive that it is Beechwood; he says he knows that Melon perfectly well, and that it entirely corresponds in all particulars; that he had the seed of the Melon from which it is descended some eight or nine years ago when in the service of the Earl of Meath, near Dublin, and that he has carefully preserved the seed of the successive generations year by year. He says that the soil at Valencia is peculiarly suited to the growth of Melons, and has no other way of accounting for the extraordinary size."

WORK FOR THE WEEK.

KITCHEN GARDEN.

Promptly clear away the remains of all crops as they decay. Quarters which require to be trenched during the autumn should be kept free of any crops after this time, in order that the work may be performed before winter. The weather is now favourable for destroying weeds. *Celery*, the ground is in good condition for earthing this up, and its quality depends to a considerable extent on the care bestowed in doing so, and on earthing-up in time. Some of the very latest crop may also be planted in rows to remain through the winter. The haulm of Peas, stored now in a dry place, is a good material for covering Celery during severe frost. *Cabbage*, the seedling plants intended to stand through the winter must now be pricked out in nursery beds of light soil at 5 inches apart; this will cause a stocky hardy growth. The July sowing of *Endive* may now be pricked-out on a warm border, and as the early plantation attains a proper size, the plants should be tied for blanching. No time should be lost in storing the crops of *Onions* when dry, as the ground from which they are taken is generally used for Cabbages; it should be immediately trenched-up, and if manure is necessary, let it be laid on the top of the trenched soil and fork it in. If, however, the ground was well manured for the Onions, it ought to carry the Cabbages without further manuring, and they will thus always come in better, because if too much manure be in contact with the roots in the autumn, it causes a succulent luxuriant growth, which renders the crop more liable to injury from alternations of frost and thaw in winter. *Lettuce*, a small patch of Bath Cos sown now will, if the autumn prove mild, be more valuable than that sown earlier. Now is the last time to make *Mushroom-beds* out of doors. *Winter Spinach* and *Turnip* beds must be kept hoed, and the plants thinned out, the former to 9 inches or so apart.

FRUIT GARDEN.

It will be an advantage to have the fruit-tree borders free and unshaded by any crop at this season; planting Endive, Turnips, and similar crops, keeps the border cold and wet when warmth and air are more particularly required. It would even be more satisfactory to reduce the width of the borders, if even a more limited space could be exclusively secured to the wall trees. If sufficient material, such as sods of sandy loam are not in hand, no further delay should take place in collecting enough for carrying out any proposed alterations.

FLOWER GARDEN.

A surplus stock of bedding plants should always be provided against contingencies. The propagation of Heliotropes, Verbenas, Pelargoniums, and Calceolarias should be proceeded with, as the general utility of these plants for decorative purposes is unquestionable. Chrysanthemums out of doors should be carefully staked; if against a wall, where they thrive better, they should be trained while the shoots are succulent. Propagate them by cuttings for blooming in pots. Budded Rose stocks should be carefully attended to. It is time that buds which have started should be encouraged to form a more vigorous growth by stopping the wild branches of the stock. If Pansies are to be grown well the bed must be renewed yearly, and in order to insure a good spring bloom, the young plants obtained as cuttings or side shoots from the old favourites, in addition to any new varieties which may be bought, should be soon planted. The bed for their reception should be prepared in order that they may be turned out in the end of the month. Auriculas will now begin to excite and require more attention; all decaying leaves must be removed, and occasional top-dressings given. From the wet weather early in the season, it is possible we may have a fine dry autumn; therefore, they must be kept in a moist state, never allowing them to become thoroughly dry. Examine seedlings that are pricked out; if the roots are raised above the surface, which is often the case, re-insert them by making a notch in the soil with the handle of a budding-knife, or a piece of ivory. Pinks should be planted out without delay. Look after seed of Carnations and Picotees, and carefully examine all pods, as the late dry weather has been favourable for ripening. The soil for potting-off the layers ought to be in readiness, keeping it, if possible, under an open shed. Dahlias must, to insure success, have unremitting attention. Take off all blooms which are not promising, and cover, &c., as required.

GREENHOUSE AND CONSERVATORY.

Continue to introduce plants, for however fine the days may be it is dangerous to trust anything out of doors at this period of the year. Cloudless days are very delightful, but it frequently happens they are succeeded by nights as clear, and a nipping frost. Where partial protection exists, many hard-wooded plants may with advantage be allowed to remain out of doors until the end of the month. Carefully examine the condition of each plant, and remedy any defects in the soil or drainage; clear off moss, remove insects, and replace stakes. The ordinary precautions for obtaining a supply of common flowering plants throughout the winter months should be taken. Violets should be potted or planted in a frame; Mignonette thinned and sown; Hyacinths, Tulips, and other bulbs potted and plunged; Pinks for forcing encouraged; and Cinerarias duly attended to. Roses in pots should occupy a fair share of attention; young plants may yet receive a shift, and manure water may be applied to plants in active growth.

STOVE.

Twiners on the roof should now be more than ever kept within bounds, cutting back all shoots that have done flowering, and tying the others so as to obstruct light as little as possible. Place specimens ripening their wood in the coolest part of the house, and water sparingly at the roots. Achimenes, Gloxinias, and Gesneras that are properly ripened-off may be stored in any dry place where they will be secure from frost, but take care to place them where they will be free from damp, and they should not be exposed to a lower temperature than 45° or 50°. Many valuable plants of this kind have been lost owing to storing them in dry sheds. Hardwooded shrubs, such as Ixoras, that have not made their wood after flowering, should be encouraged with a warm moist temperature, syringing them lightly overhead, and shutting-up the house early in the afternoon. Let any growing plants that require more pot-room be shifted as soon as convenient, in order that they may be well-rooted in the fresh soil before winter. Keep a sharp look-out for insects, especially thrips, which are often troublesome at this season on such plants as are growing in a close warm house; either fumigate or remove the plants affected, and thoroughly clean them as soon as this pest is perceived.—W. Keane.

DOINGS OF THE LAST WEEK.

Never was there such a change as from August 28th to 29th, pretty well roasted the one day and frozen the next. The evening

of the 29th was piercingly cold, and on the 30th and the three following mornings we had hoar frost thick on the grass, and a thermometer showing from 1° to 2° below freezing-point. Some fine scarlet Pelargoniums were blanched a little in consequence. A few Perillas on raised beds were touched, whilst others on the level were not at all affected. Almost every kind of Coleus was affected, except the brown Coleus Verschaffelti, and Dwarf Kidney Beans passed uninjured. The cold would have had a greater effect but for the dryness. On the 29th we heard of heavy rains farther north, yet we had none that reached the ground here, but a singular phenomenon presented itself during fully half the day. There seemed to be more than a thick Scotch mist in the air, and as you looked at it between the eye and some lofty trees, you could see the rain drops thick and eddying in great waves, as if resolved to give everything a refreshing shower, but so far as we saw not a drop reached the ground, the roads being dust-dry all day. The only exception took place beneath lofty trees, as from the highest branches and leaves there were droppings of moisture. No week could have been more suitable for harvest operations, and the fields are being fast cleared. A good rain would greatly help the Turnips.

In the kitchen garden and fruit garden, besides sowing Cauliflower for the last time, and Lettuces, the work has been mostly a continuation of that largely dwelt on in the notices of previous weeks, chiefly surface-stirring, watering, planting, &c. We shall just allude to some matters shortly this week, as more prominently coming under our attention.

Wasps.—For a few days we were quite overrun with these, but the cold nights seemed to have much lessened their numbers, so that as yet we have not put up hand-light traps or bottles to catch them. We feared for our Morello Cherries, as even with the best covering the wasps will find their way to them, and therefore we gathered all the fruit, thinking it safest in bottles, however preserved. Currants, &c., are not safe from their depredations, unless under gauze or fine wire netting. Gooseberries with us are just over. We have often had the Warrington in a shady border very fair in October.

Cabbage Butterfly, and Moths.—We lately alluded to the extraordinary numbers of the ladybird this season, and the popular errors respecting it as destroying the Bean crops. We never saw so few moths as we have done this season. Our Cabbages and Cauliflower have suffered a little from dryness, but that is an evil not felt where there is abundance of water; but in such a summer we often have had in addition whole clouds of white butterflies depositing their eggs, on all the Cabbage tribe especially, followed by myriads of larvæ, which threatened to clear all before them. Finding cleaning and liming the foliage a troublesome operation, when we had young boys we used to send them on the pleasant work, to them, of hunting down the butterflies, and it was amazing how many they would capture in a sunny forenoon. We do not think we have seen half a dozen white butterflies during the season, and yet the winter was so mild, so free from frost. It just confirms what we lately referred to, the falsity of the common idea that a continued severe frost is good for ridding us of grub and insect enemies. The reverse is often the case. Their instinct tells them how to guard against all such casualties, by securing warm places, or going down greater depths in the soil. In mild winters they are encouraged to make their appearance too soon, and are killed by the succeeding cold. This theory seems at least plausible, and is so far confirmed by results. We have noticed the same thing frequently with self-sown annual seeds. When a sharp frost had set in about the beginning of November, and the first part of the winter was cold, the seed, not having vegetated, would withstand the cold and come up strongly in spring; on the other hand, when the winter was mild up to Christmas and afterwards, and then we had severe frosts in January, February, and later, there were fewer plants from self-sown seeds, or even sown by hand, because they had vegetated in the first part of the winter, and were cut up by the following frosts. We have noticed this chiefly in the case of annuals not quite hardy under general circumstances, as there are some of our annual weeds that no frost or changes seem able to destroy. We have rarely known the smallest plants of Thistles or Groundsel injured; even seeds which have just germinated, do not seem to suffer, but many young seedlings do, and in this case there may be an analogy between them and insects, as respects the effects of mild and severe winters.

ORNAMENTAL DEPARTMENT.

Besides putting the flower gardens and pleasure grounds in first-rate order, making lots of cuttings, &c., we may mention the following:—

Lavender.—There is no better mode of making a plantation than taking off slips in autumn or early in spring, and planting them firmly at once. To have the Lavender healthy, and for it to continue so, the ground should be well stirred, but not much enriched. We have seen many instances in which greater vigour was required, where it was better to enrich with surface-dressings instead of digging manure into the soil. As the stalks have opened about half their flowers they should be gathered and sorted, and no plan is better for keeping than tying in small bundles and enclosing in muslin bags. What falls off, or even the stalks chopped, come in useful for mixing with Rose leaves. On the manufacture of oil of Lavender, Lavender water, &c., it is not our province to enter.

Biennial plants, as Canterbury Bells, Sweet Williams, and even Wallflowers, Daisies, Heartsease, and Violets, should now be planted-out, or pricked-out to be planted when the ground is cleared. All *Violets* will need watering when the weather is dry. Our beds of Neapolitan Violets have been several times cleared of runners, as we mean to lift and transplant with balls under glass in a month or so. A little red spider and mildew made their appearance on them, owing to the dryness, and, therefore, they were dredged a little with soot and sulphur, and syringed with clear water a few days afterwards. It is advisable always to have them clean before placing them under glass.

Hollyhocks, Dahlias, Phloxes, &c.—Hollyhocks have been fine this season, without having a drop of water given to them. When in masses, we often fix them in rows by running a stout string from stake to stake, and fastening the stems individually to the string, and thus a few stakes serve for a row or belt. We should remember that it must be a fine stake that becomes any ornament in itself. The aim should be to conceal all such necessary propping as much as possible. We have seen Dahlias so spread out and staked, as to be perfect deformities to the eye—to be grown, in fact, as if for the purpose of having a forest of sticks put in about them. The only way to render Dahlias a pleasing feature to the eye, and thus have every plant symmetrical and natural in outline, is to have only one stake to a plant, and that not quite so high as the top shoots. We are supposing that each plant, as it ought to be, is grown to one stem. This is secured to the stake as it grows, and then all side shoots are secured in their natural position by passing a looped string from the stake round the under side of the side branch. A Dahlia may thus be rendered secure from the force of the wind, and the weight of rains and heavy dews, and yet show neither stake nor tying.

Time of Watering.—With scarcely any watering the flower beds, when not interfered with by intruders, are rather better than on the average of seasons. If we must water some of them, and most likely such free-growers as Salvias and Calceolarias may want it, we shall prefer giving the water in the forenoon, instead of in the afternoon, that the surface soil may be dry before evening. As we may expect the nights to become cooler, all plants in pots out of doors we shall now, as a rule, water early in the day, so that the pots and soil may not be so much cooled at night. Many plants that would not suffer in the least from a little cold at their tops, will be much injured by the free exposure of a damp pot to the air, more especially if the young roots are clustered near the sides of the pot. Plunging, or something wrapped round the pot, would prevent many a casualty. Where that cannot be conveniently done, all tender plants should be placed under cover before long. The mere standing exposed in a pot, even when the precaution of watering in the first part of the day is taken, exposes plants to more danger than if they were planted or plunged in the ground. At one time, for a furnishing purpose, we used to grow Dahlias, and they succeeded admirably in 12-inch pots, but year after year we found the plants in pots suffered from cold some days and even weeks before their neighbours which were planted out in the usual way, even though the latter were more luxuriant, and on that account more liable to injury. This we considered was owing to the free exposure of the pot, because when the pots were plunged, the plants withstood the cold of autumn better than those planted out.

Pinks, Cloves, Carnations, and Picotees.—Rooted slips if planted out now will be well-established before winter; nevertheless, where a spare frame or cold pit can be given them, we prefer potting fine kinds, and sheltering them during the winter, not so much to protect them from cold as from their many enemies. We have had and lost several good collections

from the incursions of enemies. Slugs, &c., are bad enough, but they are nothing compared to rabbits, rats, and mice. We once had several hundreds of good kinds, pretty plants in 4-inch pots, cut down to the surface of the pots in one night by rats, and in the pleasure grounds we have found massive beds like a desert in the spring by the incursions of hares and rabbits. Hardly any fence will keep such intruders from them, nothing but a solid wall which they cannot leap. Efforts must be made to have the plants referred to somewhere, as for cut flowers they cannot be dispensed with.

Cutting-making.—This has formed one of our chief employments, so as to provide for the flower garden next year. We have already alluded to particulars. It is of importance to strike all we can in a cool place. Verbenas, Petunias, Lobelias, Ageratums, and Pentstemons, do better under glass, shaded by day, kept close, and with a little air at night, which prevents drawing and damping. The air at night is very essential. The simpler and lighter the material in which they are put the better. All mixture of old soil should be avoided if possible. Nothing is better than the sandy gritty loam which is obtained from the sides of the highways, with a sprinkling of sand or road drift. If leaf mould or dung is mixed with it, there is the chance of fungus troubling the cuttings and young plants. Bedding Pelargoniums will still strike well enough in the open air. A little flagging is of no consequence. The cuttings of all such plants as Verbenas should be drawn through weak tobacco or quassia water, as it is better to secure the cuttings being clean than to clean them afterwards.

Where gorgeous beds and borders are desired, neither a cutting nor a bloom should ever be taken from them until the latter is faded. What we advocate in this respect, we have not been able to practise. We have no space in which we can form mixed borders for cuttings and cut flowers. We must take both from beds and borders that come prominently before the eye, but no one feels the impropriety of doing so more than we do. We, therefore, delay as long as possible taking off cuttings, and these and numbers of cut flowers diminish the symmetry and massiveness of the beds. Lately we took about two hundred cuttings from a line of Bijou Pelargonium, and we wished afterwards we had delayed for a week. Where there are large kitchen gardens, borders for flowers and cuttings could easily be placed there, and the show beds remain as such.—R. F.

COVENT GARDEN MARKET.—September 8.

A very slow trade indeed, with little signs of improvement. Importations have largely added to our stocks this week, which comprise all the usual varieties of Pears and Apples at this season. Plums are sufficient for the demand.

TRADE CATALOGUES RECEIVED.

James Carter & Co., 237 and 238, High Holborn, London, W.C.—*Carter's List of Dutch Bulbs, Fruit Trees, Roses, &c., for* 1869.

D. Gold McKay, Market Hill, Sudbury, Suffolk.—*Catalogue of Dutch Flower Roots, Seeds for Autumn Sowing, Herbaceous Plants, Roses, Fruit Trees, &c.*

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Select Dutch Flower Roots, &c.*

Smith & Simons, 36 and 38, Howard Street, St. Enoch Square, Glasgow.—*Dutch Root List.*

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Hyacinths, Narcissus, &c.—List of Strawberries.*

Stuart & Mein, Kelso.—*Descriptive Catalogue of Choice Hyacinths and other Dutch Bulbs.*

Hooper & Co., Central Avenue, Covent Garden Market, London.—*Autumnal Supplement to Hooper & Co.'s General Catalogue, containing Descriptive Lists of Dutch and other Bulbs, &c.*

Robert Parker, Exotic Nursery, Tooting, Surrey.—*Catalogue of Hyacinths and other Bulbous Roots, Fruit Trees, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*An Old Subscriber*).—"British Ferns," price 3*s.* 6*d.*, or free by post from our office for 3*s.* 10*d.* (*W. C.*).—You can have the "Cottage Gardeners' Dictionary" free by post from our office if you enclose 7*s.* 2*d.* in postage stamps with your address.

Verbenas for Exhibition (*A Learner*).—The following are six good kinds for the purpose—viz., Foxhunter, Mrs. Reynolds Hole, Mrs. Perry, Madame H. Stenger, Géant des Batailles, and King of the Lilacs. The "Cottage Gardeners' Dictionary," 6*s.* 6*d.*, or free by post 7*s.* 2*d.*

Seedling Pelargonium (*H. O.*).—It is impossible to give an opinion without seeing the flowers.

Dinder Lodge (——).—The information in the "Horticultural Directory" is quite correct.

Quercus Cerris (*W.*).—This, the Turkey or Mossy-cupped Oak, like all the species, flourishes most on a deep rather tenacious soil, but we have seen good specimens on a light soil; and a chalky soil would probably produce it well if of good depth.

Culture of Leptopteris superba (*J. W. K.*).—The temperature and moisture of your Fern house is too uneven for the Leptopteris. It should be potted in a compost of two parts sandy fibrous peat one part yellow light loam, and one part grit or sandstone, in pieces not larger than a hazel nut, nor less than a pea. Use a pot just large enough to hold the roots well, and allow for an increase in growth. Drain it well, and place it in a pot or pan, so that the rims of the two will be on the same level, placing the inner one on crocks. The outer pot should be large enough to contain the fronds without their touching the glass they are to be covered with. Fill the space between the pots with crocks to within an inch of the rim, and the remainder of the space with charcoal made small, sifting it first through a half inch sieve, then through a sieve with an eighth-of-an-inch mesh, and use what remains in the sieve. Cover with a bell-glass having holes in the top. It should rest on the charcoal. The glass should be taken off every morning and wiped dry. If the bell-glass have three holes at top, it will give sufficient ventilation. We find the plant succeeds well when thus treated, or in a house kept uniformly moist, but not from syringing over the fronds; avoid that. A glazed frame is useful for such plants.

Marchioness of Hastings Grape (*W. E.*).—It produces very large, loose bunches, with watery and flavourless berries. Its only recommendation is its size. It is an early Grape, and ripens in an ordinary vinery.

Muscat Grapes (*An Old Subscriber*).—They are only slightly rusted, and being ripe, it will not injure their quality. Rust, we believe, is induced by sudden exposure to cold currents of air.

Grapes (*T. G. Partridge*).—We do not know any private garden in which the Ulliade noir and Schiras are cultivated, but you may see them in the Royal Horticultural Society's garden at Chiswick.

Vines not Growing (*A Beginner*).—The shoot and leaves are attacked by red spider. Little can be done this year beyond syringing the Vines every morning and evening, and shutting up the house early in the afternoon. Continue this treatment throughout the present month, after which the house should be kept drier. Air should be given early in the morning, so as to have the foliage cool and the air in motion when the sun shines powerfully, otherwise the leaves may become spotted. A good watering ought to be given the roots without delay, and repeat it in a fortnight. Cut the Vines back to two or three eyes in December, and paint them with sulphur brought to the consistency of paint by mixing with it 8 ozs. of soft soap to a gallon of tobacco water. Apply the sulphur mixture with a brush, rubbing it well into every crevice, but being careful of the buds. The house ought to be thoroughly cleaned,

and the walls washed with lime and sulphur in equal parts, brought to the consistency of whitewash by 4 ozs. of soft soap to the gallon of water. Do not give the Vines very much water until they are growing freely, then afford copious supplies every fortnight or three weeks, and maintain a moist atmosphere by sprinkling the paths, walls, &c., twice or thrice a-day. Select the strongest shoot, train it carefully, stop the laterals at the second or third joint, and when they break again let them make three or four leaves, and then take out their points. We think the Vines will grow next year

Vine Leaves Discoloured (*J. H.*).—The leaves are very like those of the Espiran, but you say they are from the Black Hamburgh. We believe the discoloration arises from the leaves being formed in or exposed to a cool, moist atmosphere, followed by heat or much sunshine. They are unprepared for the consequent excessive evaporation, and ripen prematurely and assume their autumn tints. Such foliage is often a sign of good, rather than bad health. Perhaps a slight shade for a few days in bright weather, after a dull period, would prevent the discoloration, but we do not advise shading for Vines, or only of a very temporary description. The best time to lift Vines is early in March, or before the eyes begin to swell. We do not think the discoloration arises from the roots being deep, but the contrary, and we do not advise the lifting of Vines as long as they continue to produce good crops and firm, well-ripened wood. Besides, Vines five years planted cannot now require lifting if the border is good, and means have been adopted to prevent the roots going down into bad soil; indeed, the roots ought to be restricted to the border by a concrete or flagged bottom, and walls at the sides and ends. They are then entirely under command.

Vines Breaking (*Norwood*).—We can hardly understand about the Vines you want to start in January breaking now. You had better let them alone. Give them all the air possible; if very hot, even shade; and defer pruning till the end of October or November. If the Vines are breaking and you prune now, you must keep on growing them; better defer in ordinary circumstances.

Placing Pot Peach Trees out of Doors—Pots for Vines (*Reader*).—There will be no danger in leaving your Peach trees in pots out all the winter if the pots be plunged and mulched, and the buds protected from birds and very severe frost. Probably the trees in the vinery were too much shaded. Most likely the Vines planted out in July received a little check. They should have been shaded at first. No doubt the roots are catering for themselves. Your pots 2 feet deep and 20 inches in dismeter are ample in size for Vines in pots. Instead of enlarging the size of the pot we would mulch and top-dress with rich material. This will prevent all starving at any period.

Peach Tree Dropping Its Fruit (*J. B. L. H.*).—As the tree, the fruit of which we do not recognise, is so healthy, the dropping of the fruit prematurely is owing most likely to excessively vigorous growth and the full ripening of the wood. We would continue giving plenty of air and abundance of water after the fruit is fairly set and swelling; but when it is ripe we would give but little water, and be more anxious to harden the wood than to keep it growing. Allowing a tree to become dry and then watering freely will often cause the fruit to fall. It is safest to water a width of, say, 3 inches from the wall at a time, and then follow in a few days with 24 inches or more in width.

Peach Trees Infested with Aphis (*Old Correspondent*).—The Peach leaf sent is infested with the brown Peach aphis. It may be destroyed by an efficient syringing with tobacco water, that of the shops being diluted with six times its volume of water, or it may be made by pouring a gallon of boiling water over 2 ozs. of the strongest shag tobacco, cover up closely, letting it stand until cool, and then straining, applying to the trees with a finely-rosed syringe, thoroughly wetting the trees in every part. The best means of riddance is fumigation with tobacco, the house being made quite full of the smoke, so that a plant cannot be seen through the glass from the outside. The size of the fruit would be increased by top-dressings with rich compost, and abundant supplies of water, and occasionally liquid manure. Probably too many Peaches are left on the trees, so that the trees are unable to swell the fruit to a good size.

House for Pine-Apple Culture (*H. S.*).—Both a lean-to and a span-roofed house are good for the purpose, but had we our choice we would have a span-roof, wide enough to have a walk all round, and a walk down the centre, with a bed on each side, and we would heat each bed beneath, either with pipes or a tank, or both, and have enough of top heat for the atmosphere of the house. Thomson on the Pine Apple is plain, terse, and much to the purpose. The "Pine Apple Manual" would probably suit you, and may be had from our office by post for 2*s.* 8*d.*

Peaches Mealy (*Idem*).—Peaches become mealy and fall off, chiefly from a too heavy crop, or from some irregularity as to moisture at the roots. Stagnant water will cause them to fall, so will too much dryness, and dryness succeeded by abundant watering at once. It is better to water gradually.

Lilium auratum after Flowering (*A. Y.*).—Pot it as soon as the leaves fall and the stem becomes yellow. Do not disturb the roots, merely remove any loose soil. Give a moderate shift. Equal parts of fibrous loam, sandy peat, and leaf mould will grow it well. Drain the pots well, give a gentle watering after potting, and keep the soil just moist during the winter. In potting leave space for top-dressing in spring. Winter in a pit or house from which frost is excluded, though a few degrees of frost will not injure the roots if the pots are plunged. Do not take the bulbs up.

Tropæolum tricolorum Culture (*Idem*).—It ought to be potted without delay, indeed it will soon be in growth. It is well to use a rather small pot, say one 6 inches in diameter, and place it in one of larger size, so that the rims of both may be on the same level, filling the space between halfway up with crocks or the roughest part of the compost. This may consist of two parts light fibrous loam, one part peat, one part leaf soil or old cow dung, and one-sixth silver sand. Cover the bulb with soil, and keep the soil moist. Never overwater. Commence training early. A light airy position in a greenhouse with a winter temperature from fire heat of 40° to 45° suits it. It will flower next March or April.

Tropæolums for Winter Decoration (*A Salopian*).—Tropæolums are excellent for winter decoration. We employ the Lobbianum varieties. Triomphe de Gand, Brilliant, and Elegans, we like best. We grow them in two ways—as climbers, and as pot plants; in the first case we take off cuttings in spring, or early in summer, pot as required, and shift into 9-inch pots in August, or at the beginning of September. The shoots are trained to wires fixed about 9 inches from the glass, but they will succeed equally well on trellises in a light situation. Triomphe de Gand is best for this purpose. The soil used is a mixture of turfy light loam, old mortar rubbish, or broken pots, leaf mould or old cow dung, in equal parts. Good drainage is necessary. Pot plants we raise from cuttings inserted at the end of July, or early in August, in a gentle heat, placing one cutting in a 3-inch pot. When the cuttings are rooted, we pinch out their points three joints from the soil. When they begin to grow again we harden them off, remove them to a cool, airy house, shift into 4½-inch pots, and to each place a neat stake painted green, and not more than 18 inches high. Tie the shoots to the stake, and pinch off all flower-buds as they appear, stopping when the shoot has grown 6 inches. When it again pushes select a leader, tie it to the stake, and pinch out the points of the side shoots when they have grown so as to have three or four joints, and stop the leader when it has grown 6 inches. Shift into a 6-inch pot, and stop again at the third joint. The leader will now be at the top of the stake. The plants will now begin to flower; keep them compact by stopping at the fourth leaf. They will continue to grow and bloom most of the winter, in a temperature of 45° to 50°. If larger plants are wanted, 7, 8, or even 9-inch pots may be used. Give no more water than enough to keep them fresh. When the soil becomes dry, give a good supply. The tuberous-rooted Tropæolums, as tricolorum, Jarratii, &c., are also good. Some notes on their culture will be found in answer to another correspondent. They are very handsome if trained to a wire trellis, or to the top of a young Spruce or Larch, 2 or 3 feet high, and the twigs of the Spruce or Larch covered with the wire-like shoots of the Tropæolums, the pretty bright green leaves, and rich orange, yellow, and brown flowers, have a fine effect on the centre of a dinner-table. The Larch tops make excellent supports for this class of plants much better than wire trellises. The tops should have parted with the bark, or it should be removed, the shoots thinned out, and the twigs equally disposed, widest at bottom, and gradually tapering upwards like a cone. Except for dinner-table decorations, and particular purposes, so much care need not be taken.

Salt as a Manure for Strawberries (*W. I.*).—We should have no idea of, as you say, "pickling" Strawberry plants even in winter, but a little thrown between the rows would be beneficial rather than otherwise. No doubt salt would help to keep the soil moist. A Potato that grows only 7 inches in height and ripens its tubers in two months from the time of planting, would no doubt be useful for pot culture.

Flower-garden Arrangements (*D. C.*).—Your arrangement of the flower de lis will look very well, but we would border all; thus, instead of mixing 2, 2, in the first, we would centre with Golden Chain Pelargonium and edge with Viola cornuta; and if we edged 3 with white Alyssum we would centre with a purple or chocolate-coloured Verbena Similar remarks may apply to the second group. The circles 4 and 18 may be planted in almost any way, as they form no part of the groups. They will look very fair, though we do not much like the Beet so near so many pretty plants. (*Vitis*).—We have no doubt you can make any of your proposed arrangements look well; but for the tank breaking the view we would have preferred all the border being the same We like the plan first proposed best, as the simplest and most effective. We do not enter into your proposed panelling, as we do not see how you will have room for that and so many regular rows besides. We would rather panel entirely the borders round the tank, or vandyke them, and that would make a change. Anything like intricacy in such borders generally mars the effect.

Setting a Saddle-boiler (*L. I. F.*).—Your plan of setting the boiler seems correct. A terminal saddle boiler is better than the common one, as the end of the boiler is filled up, and with one tap you can empty both sides. The great point is to have the top of the boiler considerably lower than the lowest pipes in the house; to have the flow pipe as near the top, and the return pipe as near the bottom of the boiler as possible: The advantage of having a plate 15 inches from the furnace-door to the boiler, chiefly consists in making the furnace larger, and securing when necessary a slower combustion. The smaller boiler should suit your purpose for such a small house; but as changes of purpose often take place, we would prefer the larger-sized boiler named, as the expense of setting will be much the same. The economy of working a small boiler will greatly depend on the having a close-fitting furnace, and especially ash-pit doors, also on having a damper in the chimney. As frequently stated, for general purposes a flue or brick stove is cheaper for small houses, as do what you will much heat will go up the chimney. The hot water, however, is the cleanliest way of applying heat, when a little more for fuel is no consideration.

Truss's Pipes and Joints (*A. W. L.*).—We hear that the advantages of these pipes and joints are neatness of appearance with perfect tightness. The pipes may be moved in any direction without impairing the joint; any length of pipe can be taken out in a few moments and as quickly inserted as required. They are made to any size, and are now laid by large companies to 4-feet bore. The saving in cost of work is very considerable.

Various (*Erin-go-Bragh*).—The best way of heating such a conservatory, opening into a drawing-room and dining-room, would be by hot-water pipes beneath an open trellised pathway, and the beds or tables so formed as to look most effective from the rooms. The large pond at the bottom of the garden would do well for aquatics, either planted out or submerged in large boxes, or lashed. Such as the following would suit you:—Aponogeton distachyon, Butomus umbellatus, Calla palustris Nuphar lutea, Nymphæa alba, and Hottonia palustris. There are few Ferns that would grow on the sides of such a pond, unless there were shade as well; but that noble Fern, the Osmunda regalis, would be in its element in places at the sides, made like a marsh with a little bog or heath soil. Ducks will dirty a pond, if shallow, with their movements, and a pond of any kind, so far, with their droppings. Swans will not thrive in very shallow water, and they prefer moving water to a pond, however large. They live chiefly on vegetable matter, and thus do much to keep water free from weeds, but at times they will also fare sumptuously on the young of carp, tench, &c., and such fish as are found in still water. We do not give plans or plant plans of flower gardens, but we criticise, and thus help. You may easily change to your own mind the form of the beds, and change of plan is often pleasing in itself. We ourselves have had the same plan many years, but we change the planting every season. Most likely you would be assisted by "Flower Gardening for the Many," price 4*d.*, from our office, and "Flower Garden

Plans, &c.," price 5s., where many plans and modes of planting are given. We know of nothing better for covering your paling by the side of the avenue than different kinds of Ivy, and you might relieve the sameness with Clematis, &c. We do not know the length of your Peach wall facing the south, the wall itself being slate, or faced with slate, but the following will give a good succession:—Early Grosse Mignonne, Royal George, Noblesse, Barrington, Walburton Admirable, the last a late one. By plovers, we presume you mean the lapwing or peewits, and these when tamed are more useful in a garden in disposing of grubs, snails, and insects than even Ducks, and most useful the young of the latter are, as they never scratch as hens do, and their paddle feet do little harm.

Strawberry Plants (*R. H.*).—We cannot recommend nurserymen. If you refer to our advertising columns you will see several announcements of what you require.

Applying Ashes (*W. B. C.*).—You may apply ashes to your adhesive soil with advantage. It will make the soil more free-working and open, and considerably improve the staple. The ashes should be applied in autumn, and worked into the soil, it being well in such soils as yours to throw it up in ridges in autumn, and turn it over frequently in dry frosty weather during the winter and early spring months. The soil will be ameliorated by the frost and exposure to the air, and the ashes will be more equally disposed through the soil by the frequent stirrings.

Budding Pears, Apples, and Plums (*Idem*.—It is late to bud these but you may try budding now, and if they fail you can graft in March. The stocks to be grafted next spring may be partially cut back this autumn, but not much, the heading being left until the grafting is done in spring.

Hollyhock Propagation (*Agnes*).—Of the three sorts of stems we should prefer the short stubby ones that come from the base of the plants, particulars of which you will see at pages 162 and 172 of the Journal of August 26th. No time should be lost in getting in the cuttings so as to have them established before winter.

Pinching-out the Hearts of Brussels Sprouts (*H. W.*).—We do not advise the cutting of the hearts, as it tends to bring the crop all in together, the Sprouts swelling the whole length of the stem, come in simultaneously; and by leaving them entire the plants produce a succession of Sprouts for a long time. By pinching-out the heart, however, the Sprouts become of a good useable size the full length of the plant, and can all be taken from the plant at once, or within a short period, and the ground is thus earlier set at liberty for other crops.

Hyacinths, Tulips, and Crocuses in a Pit (*Amateur*).—Your pit will answer admirably. It will not be too damp in winter, and you could employ a gentle fire in dull weather to cause a circulation of air, which would dissipate the damp, a little air being given. The flue, we presume, is not covered with the ashes, or if it be, we do not see its utility. It should run along the front of the pit and have the top, at least, uncovered. Bottom heat is not necessary. Air should be freely given in mild weather, and in severe a covering of mats over the lights will lessen the need for fire heat, and that should be kept at a minimum.

Tacsonia, Rhynchospermum, and Passiflora Culture (*E. M. M.*).—The Tacsonia not having flowered, may do so this autumn. Train the shoots out moderately thin, keeping them from becoming too crowded, so as to fully expose them to light and air. The shoots ought not to be further from the glass than 9 inches, nor nearer than 6 inches. If it do not flower, keep rather dry in winter, and in early spring thin out the weak bare shoots, and train the young growths as they proceed in their place. The Rhynchospermum should have the shoots trained in, and not too closely together, not shortening or pruning otherwise than to thin them out where too thick, and shortening when shoots are required to fill vacant space. The old bare shoots may be cut clean out, replacing with young. Give enough water to keep the foliage fresh, but inclining to dryness during the winter months. Keep the Passiflora dry at the root, and thin out the shoots so as to expose fully to light and air, thereby securing the well-ripening of the shoots. Do not prune, however, too closely at this season, for if that be done it is likely the plant will start into growth, especially if the atmosphere be moist. The dryness of the soil should not be greater than to keep the plant inactive through the winter. Moisture must be given as required to keep the wood from shrivelling. Prune in rather closely at the end of January or beginning of February, and as the growth progresses give increased supplies of water.

Hardy Ferns under a Beech Tree (*A Regular Subscriber*).—You will, we presume, have the mound formed into rockwork with stones. It will be a good position for Ferns, water being given during dry weather in summer. The following kinds would succeed:—Asplenium Adiantum nigrum, A. Trichomanes, A. viride, Athyrium Filix-fœmina and varieties, corymbiferum, multifidum, and plumosum; Blechnum spicant, and its variety ramosum; Cystopteris Dickieana, C. fragilis; Lastrea montana (Oreopteris), L. Filix-mas and variety cristata, L. rigida, L. cristata, L. dilatata, Osmunda regalis (for damp situations at the foot of the rockwork); Polypodium vulgare, P. cambricum, P. Phegopteris, P. Dryopteris, P. alpestre; Polystichum angulare and variety prolifermo, P. aculeatum, and P. Louchitis; Scolopendrium vulgare, and varieties latifolium, multifidum, ramosum majus, subcoronatum, and submarginatum multifidum. The best time to procure them is in spring, planting out at the end of March or beginning of April.

Fruit (*A Subscriber*).—Messrs. Webber & Co., Covent Garden Market. Mr. Mart is still in Oxford Street, and that direction would be sufficient.

Skeletonising Leaves (*E. F.*).—Ivy, Chestnut, Oak, and almost any other leaves with prominent nerves and veins are suitable. We know of no flower the petals of which can be skeletonised; but the seed-vessels of Physalis Alkekengi (Winter Cherry), and P. edulis (Cape Gooseberry), answer very well.

Names of Fruits (*W. Ashwell*).—The Fig you sent us was crushed as flat as it was possible for it to be. Send it again in a stouter box, and by some conveyance by which it will not be so damaged as by the post. It is a very fine-looking fruit. We had 5*d.* postage to pay, partly as a fine.

Names of Plants (*F. S. A.*).—Aster Amellus. (*Esher*).—Phygelius capensis. (*Ann Carr*).—1, Cheilanthes microphylla; 2, Tamarix gallica. (*H. C. F.*).—Bignonia radicans. Cut away the small weak shoots of the former year in winter, and shorten the strong ones to about 2 feet long, that young shoots may be obtained for flowering the following summer. (*Alfred Squires*).—Houlletia Brocklehurstiana. (*James Scott*).—1 and 2, Verbascum nigrum; 3, Pentstemon venustum or Richardsoni. (*W. Y.*).—1, Pernettia angustifolia; 2, Hypericum patulum var.; 3, Ligustrum lucidum; 4, Spiræa Fortunei. (*Henry Bottomley*).—Hibiscus syriacus.

POULTRY, BEE, AND PIGEON CHRONICLE.

LEICESTERSHIRE AGRICULTURAL SOCIETY'S POULTRY SHOW.

It is a matter of general congratulation that this Society's exhibition is resuscitated, the cattle plague having unfortunately made a break in the arrangements of this long-established institution, of which poultry has formed a most popular part for a long series of years. The care and attention bestowed on the specimens exhibited were equal to those at former meetings, and the poultry department was a most undoubted success.

Dorkings were first-rate, a couple of very fine hens in the pen shown by Mr. Warner being in excellent trim; the cock belonging to Mr. Wood in the second-prize pen was, however, the best male specimen. In chickens these gentlemen reversed their positions. *Spanish* and *Cochins* formed good classes, but we regretted to see leg-disease in a capital pen. The White Cochins, both old and young, were the gems of the Show, the chickens more particularly being the best seen this season. In *Game* fowls the chickens were the best shown, the old birds being mostly out of feather. *Hamburghs* were indifferent. *Bantams*, also, we could have wished better. *Ducks, Geese*, and *Turkeys* were first-rate. Mr. Worthington showed the best Rouen Duck that has been exhibited this season.

Pigeons were remarkably good; Messrs. Forster, Choyce, and Draycott being heavy exhibitors.

Every provision was made to prevent injury from bad weather to the birds exhibited, but the day was fine, and the attendance of visitors quite equal to the anticipations of the Committee.

Dorkings.—1, H. Warner, Loughborough. 2, R. Wood, Clapton. *Chickens*.—1, R. Wood. 2, H. Warner.

Spanish.—1, J. J. Sharpe, Kettering. 2, W. T. Everard, Alton Grange. *hc*, J. Stephens, Walsall. *Chickens*.—1, J. Stephens. 2, M. Brown.

Cochin-China (Any colour).—1, H. C. Woodcock. 2, H. Warner. *Chickens*.—1, J. Stephens. 2, A. O. Worthington, Newton Park.

Cochin-China (White).—1, A. O. Worthington. 2, Mrs. Williamson, Queenborough Hall. *Chickens*.—1 and 2, Mrs. Williamson. *hc*, A. O. Worthington.

Game (Black-breasted and other Reds).—1, H. Warner. 2, W. H. Clars, Twycross. *c*, W. T. Everard. *Chickens*.—1, 2, and *hc*, W. H. Clare.

Game (White, Piles, or any other Colour).—1, W. T. Everard. 2, T. Ragg. *Chickens*.—1, W. T. Everard. 2, H. Warner.

Hamburgh (Golden-spangled).—1, J. Stephens, Walsall. 2, Earl Ferrers, Staunton Harrold, Melbourne. *Chickens*.—1, J. Stephens.

Hamburgh (Silver-spangled).—1, H. Warner. 2, J. Faulkney, Bretby Farm. *Chickens*.—1, H. Warner. 2, J. Stephens.

Bantams (Gold-laced).—Prize, H. Draycott, Humberstone.

Bantams (Clean-legged).—1 and 2, H. Draycott.

Bantams (Black Clean-legged).—1 and 2, H. Draycott.

Game Bantams (Black-breasted and other Reds).—1 and 2, H. Warner. *Cock*.—Prize, Lord Manchline, Deonington Park.

Extra Stock.—*hc*, J. Choyce, Pinwall Grange.

Ducks (Aylesbury).—1 and 2, J. Choyce.

Ducks (Rouen).—1, A. O. Worthington. 2, J. Wright, Sysonby. *hc*, A. O. Worthington. *c*, W. T. Everard; J. Wright.

Turkeys.—1, J. Bleasby, Pitsford Hall. 2 and *c*, W. H. Johnson, Braunstone.

Geese.—1, J. Choyce. 2, W. Cockram, Smisby, Burton-on-Trent. *hc*, A. O. Worthington. *c*, J. W. Faux, Coleorton.

Pigeons.—*Carriers.*—1 and 2, F. F. Foster, Birmingham. *Turbits.*—1, F. F. Foster. Equal 1, W. Choyce. 2, J. J. Sharp, Kettering. *c*, F. F. Foster. *Pouters.*—1, F. F. Foster. 2, H. E. Emberlin, Oadby. *c*, J. J. Sharp; F. F. Foster. *Jacobins.*—1, F. F. Foster. 2, W. Choyce. *Fantails.*—1 and 2, F. F. Foster. *hc*, H. E. Emberlin, Oadby; H. Draycott. *c*, W. Choice. *Magpies.*—1 and 2, H. Draycott. *Any other Variety.*—1 and 2, H. Draycott. *hc*, F. F. Foster; W. Choyce; H. Draycott; J. Choyce. *c*, Lord Manchline.

Rabbits.—*Heaviest.*—1, W. Foulds, Loughborough. *Greatest Length of Ears.*—1 and *hc*, H. Warner. 2, Right Hon. P. Hastings, Donington Park. *Any other Variety.*—Prize, W. Foulds.

Edward Hewitt, Esq., of Sparkbrook, Birmingham, was Judge.

DRIGHLINGTON AND ADWALTON POULTRY SHOW.

This took place on the 4th inst., and was more successful than any which has been held by the Society for many years. The Show had grown worse and worse year after year, until it seemed probable it would cease, but the appointment of an energetic Secretary has altered things for the better; and if the prizes be augmented every year in the same proportion as in the present one, there is little doubt but ere long this will become a most important Exhibition.

Spanish.—1, T. C. & E. Newbitt, Epworth. 2, H. Beldon, Goitstock, Bingley. *hc*, J. Thresh, Bradford.

Dorkings.—1, E. Leech, Rochdale. 2, J. Codd, Idle. *hc*, H. Beldon.

Cochins.—1 and 2, C. Sidgwick, Ryddlesden Hall, Keighley. *hc*, H. Firth.

Brahma Pootra.—1, E. Leech. 2, J. T. Wood, Saddleworth. *hc*, M. Scott.

Game.—*Black-breasted or other Reds.*—1, and Cup E. Ackroyd, Bradford. 2, H. Jowett, Idle. *Duckwing or other Grey or Blue.*—1, H. Jowett. 2, G. Noble, Staincliffe. *hc*, J. Fell, Adwalton. *Any other variety.*—1, R. Hemingway, Shell. 2, J. Brook, Gomersal. *hc*, R. Turner, Drighlington.

Hamburghs.—*Golden-spangled.*—1 and 2, H. Beldon. *Silver-spangled.*—1 and 2, H. Beldon. *Golden-pencilled.*—1, W. Clayton, Keighley. 2 and *hc*, H. Beldon. *Silver-pencilled.*—1, Cup, and 2, H. Beldon. *Black.*—1, C. Sidgwick. 2, H. W. Illingworth, Idle. *c*, W. Brown, Birstall.

Any other Distinct Variety.—1, H. Beldon. 2, J. S. Senior, Dewsbury.

Game Bantams.—1 and *hc*, W. F. Entwisle, Leeds. 2, J. Ramsden, Drighlington. *c*, J. Fell, Adwalton.

Bantams (Any other variety).—1, H. Beldon. 2, J. White, Netherton, Wakefield. *hc*, T. C. Harrison, Hull.

Turkeys.—1, E. Leech, Rochdale. 2, J. Saville, Birstall.

Guinea Fowls.—1, W. Buttrey, Gildersome.

Geese (Any variety).—1, E. Leech. 2, J. White.

Ducks.—*Aylesbury.*—1, E. Leech. 2, D. Render, Adwalton. *Rouen.*—1, J. White. 2, J. S. Senior, Dewsbury. *hc*, C. Sidgwick; E. Leech; H. Jowett; J. Ward, Drighlington.

Any Breed.—*Cock.*—1, J. White, Wakefield. 2, H. Jowett. 3, T. Denton, Southowram. *hc*, C. Sidgwick, Keighley; H. Belden; J. S. Senior; T. C. and E. Newbitt.

PIGEONS.

Carriers.—1, J. Hawley. 2, H. Yardley, Birmingham.

Pouters.—1, T. Tetley, Birkenshaw. 2, W. Ackroyd, jun., Birkenshaw.

Tumblers (Almond).—1, J. Hawley. 2, H. Yardley. *hc*, W. Lund, Shipley.

Tumblers (Any other variety).—1, J. Hawley. 2, W. Lund. *hc*, H. Yardley, Birmingham. *c*, H. O. Steel, Gomersal; J. T. Lishman, Girlington.

Barbs.—1, H. Yardley. 2, J. Hawley. *c*, W. Lund.

Antwerps.—1, J. T. Lishman. 2, B. Field, Birkenshaw; J. S. Senior, Dewsbury; S. Smith, Bradford. *hc*, J. Dawson, Gildersome; W. Lund.

Turbits.—1, T. C. & E. Newbitt. 2, W. Lund; H. Yardley; J. T. Lishman. *hc*, J. Hawley.

Fantails.—1, J. Hawley. 2, T. C. & E. Newbitt.

Jacobins.—1, T. C. & E. Newbitt. 2, J. Hawley.

Trumpeters.—1, J. S. Senior. 2, J. Hawley. *hc*, H. O. Steele; J. T. Lishman.

Any other Variety.—1, J. T. Lishman. 2, J. Hawley; S. Smith; J. T. Lishman. *hc*, J. Thresh; W. Lund; H. Yardley; H. O. Steele. Extra prize for greatest number of points.—J. Hawley.

Judge.—Mr. E. Hutton, Pudsey.

BLACKPOOL POULTRY SHOW.

This took place on September 2nd. The entries were not very numerous. The following are the awards:—

Spanish.—1, C. W. Brierley, Middleton. 2 and *hc*, J. Leeming, Broughton.

Dorkings.—1 and *hc*, J. Smith, Manchester. 2, W. H. Butcher, Lea.

Cochin-China.—1, C. W. Brierley. 2, Miss Jackson, Garstang.

Game.—1, C. W. Brierley (Brown Red). 2 and *hc*, W. Haughton, Inskip (Black Red).

Hamburghs.—*Golden-spangled.*—1, Miss Jackson, Garstang. *Silver-spangled.*—1, Miss Jackson. 2, J. Leeming, Broughton. *Golden-pencilled.*—1 and 2, B. Bee, Goosnargh. *Silver-pencilled.*—1 and *hc*, B. Bee. 2, C. Moore, Poulton. *Any other Variety.*—1, J. Noblet, Layton. 2, J. Partington, Leigh. 3, J. Smith.

Game Bantams.—1, J. Walker, Halifax. 2, W. Milner, Inskip. *hc*, Bonny & Davis, Blackpool.

Bantams (Any other variety).—1, J. Walker, Halifax. 2, R. B. Riley, Halifax.

Game Cock.—1, C. W. Brierley. *hc*, W. Haughton.

Ducks.—*Aylesbury.*—1, B. Bee. *c*, W. Milner. *Any other Variety.*—1, C. W. Brierley (Rouen). 2, M. B. Riley, Hipperholme (Rouen). *hc*, C. W. Brierley; J. Smith.

Geese.—1, W. H. Butcher, Lea. *hc*, J. Grime, St. Michael's.

Ornamental Fowls.—1, C. W. Brierley.

WAKEFIELD POULTRY SHOW.

This Show opened on the 2nd inst., and was very creditable to the Managers. The poultry and Pigeons were exhibited in pens in a large tent, which admitted of excellent ventilation, and the pens (Turner's), were so arranged round the sides and through the centre as to secure two large promenades, and at the most busy period of the day no inconvenience was felt as regards either room or heat.

The *Game* were very good as a whole, but most of the adult birds were moulting. The cup for the best pen was given to adult Black Reds in fine feather and condition. *Game Bantams* were good, and the cup went to Duckwings, and in other varieties Pekins won both prizes. The *Hamburghs* were excellent though not numerous, and the cup went to a fine pen of adult Gold-spangled. Adult *Spanish* looked badly, but the chickens were well shown. The adult *Dorkings* were only of moderate quality, but the chickens were good. In this section the cup was won by such a pen of Buff *Cochin* chickens as is rarely seen, and the *Brahmas* were good throughout. *Polands* were first in the "Variety" class, and handsome *Crève-Cœurs* were second. The Rouen *Ducks* were of very great size.

There was a good show of *Pigeons*. The Carriers, winning Pouters, and Trumpeters were exceptionally good, and the Owls, Nuns, Turbits, and Jacobins were also noteworthy. In Almonds, Mr. Fulton showed a fine pen of excellent ground colour.

Among Lop-eared *Rabbits*, Mr. Hudson's excellent Tortoiseshell buck stood first, and a good Fawn second. Nothing can excel the beauty and neatness of the winners in the class for Himalayan, and the quality of fur in the Chinchilla in the "Variety" class.

Game (Black-breasted or other Reds).—1, C. Chaloner, Steetly, Whitwell, Chesterfield. 2, H. Jowett, Idle. *c*, H. M. Julian, Hull. *Chickens.*—1, C. Chaloner. 2, Master G. Crosland, Wakefield.

Game (Brown-breasted Red).—*Chickens.*—1, H. Jowett. 2, H. Hatton, Cleckheaton. *hc*, H. Beanland, Bradford; C. Chaloner.

Game (Duckwing, Blues, or Greys).—1, C. Chaloner. 2, H. Jowett. *hc*, H. M. Julian.

Game (Any other variety).—1, H. C. Mason, Drighlington. 2, J. Sunderland, Halifax. *hc*, J. W. Thompson, Southowram.

Game (Any colour).—*Cock or Cockerel.*—Cup and 1, C. Chaloner. 2, J. W. Thompson. *hc*, H. Jowett. *c*, H. Hatton. *Hen or Pullet.*—1, H. C. Mason. 2, E. A. Johnson, Wath-upon-Dearne. *hc*, Miss K. Crosland, Wakefield.

Game Bantams (Black-breasted or other Reds).—1, W. F. Entwisle, Leeds. 2, J. Crosland, jun., Wakefield. *hc*, J. Crosland, jun.; J. R. Robinson, Sunderland; G. Noble, Staincliffe, Batley.

Game Bantams (Any other variety).—Cup and 1, Miss A. Crosland, Wakefield.

Bantams (Any variety).—1, H. Beldon, Goitstock, Bingley. 2, J. White, Netherton. *hc*, J. H. Dawes, Birmingham; S. S. Messop, Long Sutton; S. & R. Ashton, Mottram; S. H. Stott, Rochdale.

Hamburghs (Gold-spangled).—Cup and 1, H. Beldon. 2, J. White. *hc*, S. & R. Ashton. *Chickens.*—1, H. Beldon. 2, E. Brierley, Heywood.

Hamburghs (Silver-spangled).—1 and 2, H. Beldon, *hc*, W. A. Taylor, Manchester. *Chickens.*—1, H. Beldon. 2, W. Bairstow, Feurncliffe, Bingley.

Hamburghs (Golden-pencilled).—1, H. Beldon. 2, S. Smith, Northowram, Halifax. *Chickens.*—1, H. Beldon. 2, S. Smith.

Hamburghs (Silver-pencilled).—1 and 2, H. Beldon. *Chickens.*—1, H. Beldon.

Spanish.—1, J. Thresh, Bradford. 2, H. Beldon. *hc*, T. C. & E. Newbitt, Epworth. *c*, J. Hornsby, Grantham. *Chickens.*—1, H. Beldon. 2, W. & F. Pickard, Thorner, Leeds. *hc*, J. Thresh.

Dorkings (Any variety).—1, W. Bearpark, Ainderby, Northallerton. 2, J. Codd, Shipley, Leeds. *Chickens.*—1, E. Leech, Rochdale. 2, Rev. E. Bartrum, Berkhampstead. *hc*, W. H. King, Sandfield, Rochdale.

Cochin-China (Cinnamon or Buff).—1 and 2, W. A. Taylor. *c*, J. H. Dawes, Birmingham.

Cochin-China (Any other variety).—1, W. A. Taylor. 2, J. Turton, Ackworth. *hc*, J. White. *Chickens.*—1, W. A. Taylor. 2 and *hc*, C. Sidgwick, Keighley.

Brahma Pootra (Any variety).—1, E. Leech. 2, J. H. Pickles, Birkdale, Southport. *Chickens.*—1, J. H. Dawes. 2, E. Leech. *hc*, J. H. Pickles.

Any other Variety not Classed above.—1, H. Beldon (Polands). 2, Hon. H. W. Fitzwilliam, Wentworth Woodhouse (Crève-Cœurs). *hc*, Hon. C. W. Fitzwilliam (La Flèche); C. Chaloner.

Ducks (Aylesbury).—1, E. Leech, 2, S. H. Stott, Rochdale. *hc*, J. T. Beaumont, Greenhead, Huddersfield.

Ducks (Rouen).—1, J. Dixon, Bradford. 2, J. White. *hc*, E. Leech; S. H. Stott; J. Dixon.

Any other Variety.—1, C. W. Brierley, Middleton. 2, J. Dixon. *hc*, A. & J. Trickett, Waterfoot, Manchester; J. Dixon.

Geese.—1, E. Leech. 2, J. White. *hc*, Rev. G. Hustler, York.

Turkeys.—1, E. Leech. 2, S. H. Stott.

Selling Class.—1, C. W. Brierley. 2, H. Beanland. *hc*, W. Firth, Birkenshaw; W. Fell, Adwalton, Leeds.

PIGEONS.

Carriers.—1, E. Horner, Harewood. 2, J. Hawley, Bingley. *hc*, E. Walker, Leicester; R. Fulton, Deptford.

Dragoons.—1, E. Horner. 2, H. Yardley, Birmingham. *hc*, J. L. Lishman, Girlington, Bradford.

Pouters.—1 and 2, E. Horner.

Trumpeters.—1 and Cup J. Hawley. 2, E. Horner. *hc*, Hudson and Burnip, Epworth; E. Horner.

Barbs.—1, R. Fulton. 2, J. Fielding, un., Rochdale; E. Horner; J Hawley; J. Fielding.
Owls.—1 and 2, J. Fielding, jun
Turbits.—1 and c, E. Horner. 2, J. Fielding, jun. *hc*, J. T. Lishman.
Fantails.—1, J. Hawley. 2, I. F. Liversidge, Newark-on-Trent. *hc*, J. Hawley; H. Yardley; E. Horner; T. C. & E. Newbitt, Epworth.
Jacobins.—1, J. Hawley. 2, T. C. & E. Newbitt. *hc*, H. Yardley; R. Fulton.
Nuns.—1, W. Croft, Killinghall, Ripley. 2, J. E. Thompson, Hull. *hc*, E. Horner.
Tumblers.—1, R. Fulton. 2, J. Fielding, jun. *hc*, J. Hawley; R. Fulton.
Antwerps.—1, E. Horner. 2, J. T. Lishman. *hc*, J. Crosland, jun., Wakefield.
Any other Variety.—1, E Horner. 2, J. T. Lishman. *hc*, H. Yardley.
Selling Class (Any variety).—1, J. Hawley. 2, Hudson & Burnip, Epworth.

Rabbits.—*Lop-eared Buck.*—1, B. Hudson, Holl. 2, T. Ingham, Leeds. *hc*, S. Hardcastle, Walmgate, York; F. Mosy, Leeds. *Lop-eared Doe.*—1 and 2, T. Ingham, Leeds. *hc*, A. H. Easten, Hull. *Himalayan.*—1, J. R. Jessop, Hull. 2, S. G. Hudson, Hull. *hc*, J. Batterworth, Stony Field, Rochdale. *Any other Variety.*—1, J. R. Jessop, Hull. 2, S. G. Hudson. *hc*, C. Rayson, Prestwich, Manchester.

Judges.—*Poultry, Pigeons, and Rabbits:* Mr. J. Douglas, Clumber, Worksop; and Mr. E. Hutton, Pudsey, Leeds.

BINGLEY POULTRY SHOW.

The third annual Show of the Airedale Agricultural Society was held in Myrtle Park, Bingley, on the 1st inst. The following is the prize list :—

Game (Black and other Reds).—Cup, H. Jowett, Idle. 2, J. Hird, Fearncliffe. 3, W. Drake, Allerton.
Game (Any other variety).—1, T. Dyson, Halifax. 2, Mrs. E. Winwood. Worcester. 3, J. Bentham.
Spanish.—Cup, F. & C. Haworth, Newfield, Haslingden. 2, W. & F. Pickard, Thorner, Leeds. 3, J. Berry, Silsden. *hc*, R. Longbottom, Bingley; J. Thresh, Bradford.
Dorkings —1, J. White, Warlaby. 2, E. Leech, Rochdale. 3, T. E. Kell, Wetherby. *hc*, T. E. Kell; D. Gellatly, Meigle.
Cochins.—Cup and 2, C. Sidgwick, Ryddlesden Hall, Keighley. 3, W. Harvey, Sheffield.
Brahmas.—1, C. Layland, Warrington. 2, E. Leech. 3, M. Scott, Cote, Idle. *hc*, D. Gellatly; J. Smith, Long Lee, Keighley.
Hamburghs (Gold-spangled).—1, E. Brierley, Heywood. 2 and 3, W. Driver, Keighley
Hamburghs (Silver-spangled).—Cup, 2, and 3, W. Bairstow, Bingley. *hc*, T. Fawcett, Baildon.
Hamburghs (Gold-pencilled)—Cup, R. Longbottom, Bingley. 2, R. Anderton, Gilstead. 3, S. Smith, Northowram. *hc*, W. Clayton, Morton Banks, Keighley; J. Smith, Gilstead; S. Burn, Whitby; H. Pickles, Earby.
Hamburghs (Silver-pencilled).—1 and 3, J. Walker. 2, H. Pickles. *hc*, H. Pickles; B. Hutton, Bingley.
Hamburghs (Black).—Cup and 2, C. Sidgwick. 3, J. Cockcroft. *hc*, Baxter & Murgatroyd, Idle.
Any other Variety Except Bantams.—1, J. S. Senior, Dewsbury (Polands). 2, J. Bowker, Keighley (Silver Polands). 3, W. Harvey.
Game Bantams.—Cup and 2, W. F. Entwistle, Leeds. 3, G. Noble, Stanncliffe.
Bantams (Any other variety)—1 and 3, Miss Robinson, Long Lee, Keighley. 2, T. C. Harrison, Hull.
Selling Class.—1, R. Berry, Silsden (Spanish). 2, J. I. Booth (Spanish). 3, M. Scott. *hc*, S. Felgate, Ipswich; F. & C. Haworth. c, J. Berry.
Ducks (Aylesbury).—1, E. Leech. 2, J. I. Booth.
Ducks (Rouen).—Extra 1, E. Leech. 2, S. H. Stott, Rochdale. 3, C. Sidgwick.

PIGEONS.

Pouter.—*Cock.*—1, E. Horner, Harewood. 2, R. Fulton, Deptford. 3, F. Crossley, Elland, Halifax. *hc*, R. Fulton. *Hen.*—1, F. Crossley. 2, 3, and *hc*, R. Fulton.
Carrier.—*Cock.*—1, E. Horner. 2, F. Crossley. 3, R. Fulton. *hc*, J. Watts, King's Heath, Birmingham. *Hen.*—1, 2, and *hc*, F. Crossley. 3, R. Fulton.
Tumblers (Almond).—Cup and 2, R. Fulton. 3, J. Fielding, Rochdale. *hc*, W. R. & H. O. Blenkinsop, Newcastle-on-Tyne; F. Graham.
Tumblers (Any other variety..—1, R. Fulton. 2, W. Whitaker, Belper (Bronze Balds). 3, J. Hawley. *hc*, F. Graham.
Barbs.—1, F. Crossley. 2, J. Fielding. 3, E. Horner. *hc*, F. Crosaley.
Owls.—1, F. Crossley. 2, D. McCollin. 3, J. Fielding. *hc*, F. Graham. Birkenhead.
Jacobins.—1, R. Fulton. 2, E. E. M. Royds, Greenhill, Rochdale. 3, J. Hawley. *hc*, E. Horner.
Trumpeters.—Cup and 3, J. Hawley. 2 and *hc*, E. Horner.
Fantails.—1, E. Horner. 2, J. F. Loversidge, Newark. 3, J. Hawley. *hc*, W. H. Tomlinson, Newark.
Turbits.—1 & 3, E. Horner. 2, R. Wilson, Thirsk (Black). c, W. R. Park, Melrose.
Dragoons.—1, E. Horner. 2 and *hc*, T. Smith, Keighley. 3, S. Smith, Bradford.
Antwerps.—1, J. Fortune. 2, C. Anton, jun., York. 3, W. Harvey. c, W. H. Mitchell, Moseley, Birmingham.
Any other Variety.—1. H. Yardley, Birmingham (Satinettes). 2, E. Horner. 3, W. Harvey. *hc*, J. Watts.
Any Variety.—1, W. Harvey. 2, W. Lund, Shipley. 3, E. Horner.

CANARIES.

Belgian (Yellow).—1, J. Smith, Bocking, Keighley. 2, J. Shepherd. 3, J. Bexson, Derby. c, J. Hollings, Bingley.
Belgian (Buff).—1, J. Smith. 3, W. Needler, Hull. 3, J. Shepherd.
Norwich (Yellow).—1, W. Heap, Bradford. 2, Allen & Baines, York. 3, J. Heaton, Fearncliffe.
Norwich (Buff).—1, J. Bexson. 2, Allen & Baines. 3, W. Heap.
Yellow Marked.—1, W. Heap. 2 and 3, J. Shepherd.
Buff Marked.—1, J. Shepherd. 2, I. Wildman, Bingley. 3, W. Needler.
Coppie.—1 and 2, J. Shepherd. 3, Allen & Baines.
Mule.—1 and 2, W. Heap. 3, W. Needler.
Any other Variety.—1, J. Shepherd. 2, G. Midgley, Bocking. 3, J. Banister, Micklethwaite.
Cock of any Breed.—1, J. Cockshott, Bingley. 2, J. Heaton. 3, W. Heap.

RABBITS.

Heaviest Rabbit.—1, H. Firth, Sheffield (Black and White Doe). 2, J. Pearson (Tortoiseshell Doe). 3, C. Gravill, Thorne.
Lop-eared.—1, S. Hardcastle (Fawn Buck). 2, T. Ingham. 3, W. Allison, Shipley.
Any other Variety.—1, A. H. Easten, Hull (Himalayan). 2, J. R. Jessop, Hull. 3, A. G. Poole (Angola). c, H. Jennings.

The Judges were—for *Poultry and Rabbits*, Mr. R. Teebay, Fulwood, Preston; *Pigeons*, D. Wolstenholme, Esq., Highgate, London; and *Canaries*, R. Gledstone, Esq., Idle.

MIDDLESBROUGH POULTRY SHOW.

The Meeting of the Cleveland Agricultural Society was this year held at Middlesbrough, and the Exhibition was excellent. The poultry were placed under two large tents, and the entries were much more numerous than in any previous year. The first-prize adult *Spanish* were a neat pen, and the winning *Dorkings* were the same. Of *Brahmas* there was a good entry, and the competition was close. Of *Game*, the first-prize Reds were fine, firm-handling birds; so were the winning single cocks. The winning *Hamburghs* were almost perfect, and an excellent pen of Houdans was first in the "Variety" class.

The Aylesbury *Ducks* were wonderful for a show so far north, and the Rouens were also quite as noteworthy for both size, colour, and marking of beak.

The *Geese*, however, were the leading feature of the Exhibition. The White Embden in the adult class were extremely difficult to judge, so large was the number, and so close the competition. The first-prize Toulouse goslings were almost as large as adult birds, and an extra first prize was awarded to an equally fine pen of White.

The *Turkeys* were large, but the young birds shown were almost all cocks. The Himalayan *Rabbits* were very pretty.

Spanish (Black).—1, W. Bearpark, Ainderby Steeple, Northallerton. 2, G. Holmes, Great Driffield.
Dorkings.—1, J. White, Warlaby, Northallerton. 2, E. Leech, Rochdale. *hc*, W. Bearpark; J. White.
Cochin-China (Buff or Cinnamon).—1, G. H. Proctor, Durham. 2, G. Calvert, Darlington.
Cochin-China (White).—1 and 2, G. Calvert.
Cochin-China, Partridge, or Grouse.—1, R. E. Brown, Wass, Oswaldkirk, York. 2, W. Barnes, Ingramgate, Thirsk.
Brahma Pootra (Any colour).—1, E. Leech, Rochdale. 2, J. Walker, Haya-Park, Knaresborough. *hc*, J. Rutherford, Kirkleatham, Redcar; Rev. J. F. Newton, Kirby-in-Cleveland.
Game (Black-breasted or other Reds).—1 and 2, T. Blackburn, jun., Broughton, Northallerton. *hc*, J. Walker.
Game (Any other variety).—1, W. Bearpark. 2, G. Pounder, Kirby Moorside.
Game Cock.—1, T. Blackburn, jun. 2, W. Bearpark. *hc*, T. R. Loy, Stokesley; G. Pounder; G. Ingledew, Great Ayton, Northallerton.
Game Bantams.—1, J. Pennington, Market Place, Thirsk. 2, W. Lawrenson, Egglescliffe, Yarm. *hc*, G. Carter, Sand Hill, Bedale; J. Ramsey; G. Holmes.
Hamburghs.—*Golden-pencilled.*—1, J. Walker. 2, W. Bearpark. *hc*, J. Webster, Whitby; G. Holmes, Great Driffield. *Silver-pencilled.*—1, J. Walker. 2, W. Bearpark. *Gold-spangled*—1, J. Walton. 2, G. Holmes. *hc*, W. Bearpark. *Silver-spangled.*—1, J. Walker. 2, G. Holmes.
Any Distinct Variety.—1 and *hc*, Rev. J. G. Milner, Bellerby, Leyburn. 2, W. T. Wilton, Ryhope, Sunderland.
Any Variety of Cross.—1 and 2, G. Pounder.
Ducks.—*Aylesbury.*—1, E. Leech, Rochdale. 2, M. Harrison, Warter, Pocklington. *hc*, Miss Smith, Stokesley; Mrs. Storey, Stokesley; W. Stonehouse, Whitby. *Rouen*—1, O. A. Young, Driffield. 2, C. Stamper, Highfield House, Oswaldkirk. *hc*, C. Stamper; E. Leech; J. Walker. *Any Variety.*—1 and *hc*, Rev. J. G. Milner. 2, S. & R. Ashton.
Geese.—1, Miss Walton, Acklam, Middlesborough. 2, E. Leech. *hc*, Mrs. Buffham, Lofthouse, Saltburn-by-the-Sea; Mrs. Braithwaite, Stokesley. c, W. Sherwood, Ingleby, Greenhow. *Goslings.*—1, Rev. G. Hustler, Stillingfleet Vicarage, York. 2, O. A. Young, Driffield. Equal 2 and *hc*, Mrs. Braithwaite.
Turkeys.—1, E. Leech, Rochdale. 2, Mrs. Braithwaite. *hc*, Miss B. Barker, Battersby, Ingleby Greenhow; O. A. Young. *Poults.*—1, Mrs. Redhead, Picton, Yarm. 2, L. Manfield, Thirsk.

Judge.—Mr. E. Hutton.

RABBITS AND THEIR JUDGES.

I was much pleased with the remark of "Himalayan," in page 197, for there is no class of exhibitors who are subject to so much annoyance, and who have so much right to complain of the conduct of committees with respect to judges as the Rabbit-fanciers. Having had more experience in these matters than most exhibitors, and being now out of the fancy, though

still taking a deep interest in Rabbits, I can add some remarks without being thought an interested party. The whole fault can be summed up in a few words—gentlemen who know nothing about Rabbits, and do not understand them, undertake the duties of Rabbit judges. Some of these judges, too, have an idea that, as compared to the poultry and Pigeons, the Rabbits are worthless, and treat them accordingly. Now, if they would take the trouble to inquire they would find that the Rabbit-fanciers are at as great an expense as exhibitors of poultry and Pigeons, and if committees will not be at the expense to provide a competent person as judge, they ought not to offer prizes. I have repeatedly heard committeemen and judges say, that the Rabbit men are the most discontented and dissatisfied of all exhibitors. Why, I ask, have they this character? If the services of a man who could judge the Rabbits aright were secured, it would soon be found that the Rabbit-fanciers were as contented a lot of men as other exhibitors.

It would be a good plan for Rabbit exhibitors to name a person they know to be a good practical Rabbit judge, so that committees may know who are the men who would be acceptable to the fancy.—M. Millinoton, *York*.

In answer to the latter part of "Himalayan's" letter, I for one see no reason why the Vice-Presidents, Committee, or Stewards of a show should not exhibit what they like, and as many specimens as they think fit. If exhibitors cannot trust the different Show Committees to appoint Judges, who will work fairly and honestly, without awarding the prize or prizes to an exhibitor solely because he is the owner of the field in which the Show is held (which one exhibitor at the Rochdale Show last year stated as a fact), they had much better keep both themselves and their specimens away. And latterly, with regard to the judging of Rabbits which seems to trouble "Himalayan" so very much, I am at a loss to know what will satisfy exhibitors, when I tell them that at the Rochdale Show this year there were three Judges appointed for Rabbits, to adjudicate in only three classes; they had six prizes to distribute amongst twenty-nine Rabbits, and yet there is grumbling, and that by our leading and oldest exhibitors.—The Winner of all the Silver-Grey Prizes at the Last Rochdale Show.

FOUL BROOD—ITS PRODUCTION AND CURE.

I have received another letter from Mr. Lambrecht, in which after sundry compliments to myself, he proceeds to combat the conclusions of Dr. Preuss. The line of argument taken by him is identical with the doubts expressed as to the correctness of the mycological theory in page 372 of the fifteenth volume of "our Journal," by that excellent observer, "R. S." Mr. Lambrecht urges that the fungi described by the learned doctor are the effect and not the cause of foul brood, and that instead of originating the disease, they are in point of fact produced by it. His letter is accompanied by an article, of which I append a translation. It is scarcely to be expected that five hundred subscribers will be found in Great Britain, but I shall be happy to receive the names of those who may be willing to subscribe, and when we see how many we can muster, will submit the list to Mr. Lambrecht.—T. W. Woodbury, *Mount Radford, Exeter*.

REPORT OF THE CURE OF VIRULENT FOUL BROOD IN THE EXPERIMENTAL HIVE AT BRUNSWICK, TOGETHER WITH MINUTES TAKEN ON THE SUBJECT.

"He who would extirpate an evil must learn to commence at its root."

The apiarian readers of this Journal will probably remember that we had been requested by the Brunswick Apicultural Society to produce foul brood in an experimental hive by the administration of fermented pollen, and then to cure the pestilence which had been thus produced. The former having been satisfactorily accomplished, as proved by the reports published in The Journal of Horticulture of the 8th of July, we now embrace the opportunity of making public the result of the latter part of our undertaking.

The experimental hive having been declared foul-broody according to the report of the 23rd of May, we in vain expected to be required by the Commission to undertake its cure; but it was only after the lapse of nearly four weeks, when the stock was declared by the commissioners to be "rotten-foul," and when one might clearly perceive that it was their intention to render the cure altogether impossible, that we were called upon to proceed. But what a sight revealed itself upon removing the crown-board, and what a task! A handful of disheartened and inactive bees were found scattered over rotten and stinking combs, and upon these we were to exercise our abilities, and prove the efficiency of our means of cure! The hive and its contents having been brought into a room with but one window, we again surveyed the disgusting rotten combs, and at once decided upon our mode of action. Had we been called upon to effect a cure three weeks before, it would have required only ordinary means, but in the present wretched condition of the hive we must resort to extraordinary measures in order to be certain of effecting a cure. We therefore took the combs from the infected hive and put them into a reserve hive, sweeping all the remaining bees on to a cloth spread in front of the entrance to the latter. We then threw various doses of powder of our own composition on red hot coals, held the infected hive over it, and let the developed gases act upon it during five minutes. These gases penetrated through the crown-board where it had been cemented by the bees, as well as through the material of which it was made, so that a bystander exclaimed, "Law! what a powerful remedy!" We then took from different bottles such fluids as we deemed most appropriate, and with a syringe sprinkled them all over the interior of the hive, into which we put frames with old comb foundations, swept the bees from the foul combs into it by means of a small brush, and finally added to them the clusters of bees which had formed against the window. The whole business occupied but a short time, and ere half an hour had elapsed the bees were returned to, and were in full flight upon, their stand, which in order to prevent infection was placed in a garden half an hour's walk from Brunswick, close to a hedge which bordered an open field.

On the 15th of July we inspected the cured hive (we live at four hours' walk—*i.e.*, 16 miles—from the place), for the first time, and what did we then see? The bees were clustering on the alighting-board, drone-combs and worker cells were filled with beautiful sealed brood, whilst on their edges were royal cells just ready for closing. The first swarm would have flown off in a few days. We now inspected all the cells, and were just going to give vent to our joy, when in the last comb we found two cells, the contents of which proved clearly that the pest had not yet entirely disappeared. We therefore at once resorted to a little after-cure, and again took leave of our child of trouble and pains. On the 27th of July we were at length invited by the Commissioners to view the hive. We went to the spot, and began the inspection, whilst twelve eyes scrutinised combs and cells, drone-combs and queen-cells, which latter had been excised by Mr. Gravenhorst to prevent swarming, but which had now been renewed in readiness for swarming as before. But we leave it to the report of the Commissioners to describe what they saw:—

"Brunswick, 27th July, 1869.

"This afternoon about four o'clock, the Examining Commission visited the experimental hive. Each comb was taken separately and examined twice over, and in order to do this more thoroughly the bees were swept off and each separate cell examined. We found the stock, to the best of our knowledge, strong and ready for swarming—royal cells about to be sealed over—and the whole colony in such excellent condition that we cannot but declare the hive completely and entirely cured of virulent foul brood.

"(Signed) "C. J. H. GRAVENHORST,
"HEINRICH OPPERMANN,
"H. HERBST
"H. WIEDENWROTH."

Foul brood, therefore, has no longer its former terrors for bee-keepers. He who is afflicted by it can free himself from it, whilst he who has been spared may stand armed and prepared if it should approach him. The means of completely curing foul brood, of keeping it from the apiary, of rendering infected honey again fit for bee-food, of at once freeing the pest from its contagious character, &c., will be published in a pamphlet by subscription. It will be printed in English, and if you find in England five hundred subscribers its price will be four thalers (12*s*.). Subscriptions are received by Mr. Gravenhorst, Brunswick, for North Germany; and by Mr. Woodbury, Mount Radford, Exeter.—A. Lambrecht, *Bornum, near Börssum, Brunswick*.

We are indebted to an esteemed correspondent for the following additional particulars of this interesting and important experiment:—

"Mr. Gravenhorst particularly requested that the means of cure should not be applied on the 23rd of May, but be post-

poned to the 17th of June, in order, first, to be more certain of the presence of virulent foul brood; second, that foul brood might reach its highest possible point of development, so as to test the process as severely as might be. Scarcely a day passed in the interval when some bee-keeper did not visit Mr. Gravenhorst, and one and all declared that there was no mistaking the presence of foul brood. To convince himself still further, Mr. Gravenhorst procured from a friend suffering from foul brood two pieces of comb and compared them most carefully, and found precisely the same appearances and smell in each. On the 17th of June Mr. Lambrecht was sent for to exercise his skill. When he saw the state of the stock, he at once said that it was a case requiring extraordinary means, and that whereas a fortnight sooner it would have been a simple matter to cure it, the case was now very different. The stock was brought into a room, the process gone through, and in about half an hour the bees were once more in the same hive in their previous situation.

"In the beginning of July Mr. Gravenhorst was visited by another well-known German bee-keeper, and in company with him examined the stock, and they found one foul-broody cell. On the 8th of July some members of the Committee discovered three or four cells in the same state, and Mr. Lambrecht was communicated with, and on the 15th of July again applied his remedy. At this date, however, the stock had nearly recovered itself; there was abundance of brood, and from twelve to fifteen royal cells. For fear of swarming, the latter together with the drone brood were removed, and the same process was repeated on the 27th.

"The above is Mr. Gravenhorst's account. He goes on to say, that at first, like Dzierzon and von Berlepsch, he was an opponent of Lambrecht's theory; but being unacquainted with chemistry, or the manner of conducting microscopical investigations, he could only speak as a practical man, and say that if proved by facts he should be satisfied; and, he adds, facts have spoken. The stock was thoroughly healthy, was fed with fermenting pollen and honey, became foul-broody, and is once more, after being subjected to the Lambrecht process, as sound as ever.

"As, he adds, a practical bee-keeper will not care whose a theory may be, whether Lambrecht's, or Preuss's, or Dzierzon's, &c.; if he has foul brood amongst his bees he will be perfectly satisfied with a means of curing it; and he ends by declaring that he and those who saw the stock are satisfied with the process used by Mr. Lambrecht."

REMOVING A LIGURIAN QUEEN.

On the 11th of April I received a hive of Italian bees from Mr. Woodbury, and on the 4th of July took an artificial swarm, which, although rather late, was a very good one. The old hive I removed a few paces off in the manner described; the swarm, although only three weeks old, was working well in a super, and during the very hot weather in June or July, I found the combs had fallen from their frames, and presented nothing but confusion. The old hive up to this time had shown no signs of breeding, and on examining the combs I could not find a queen, nor a single grub. I therefore resolved upon giving back the old queen, thinking the swarm (after having the combs which had fallen removed) would hatch another queen. This I did on August 1st, and on the 4th liberated her majesty—when to my unspeakable sorrow she was brought out dead in five minutes. I have examined the hive twice since that time, and neither time could I discover either queen or brood.

The bees have wonderfully degenerated, but not wholly left off pollen-gathering; they bring home very little; of honey there is at a guess, 40 or 50 lbs. weight. Well, to-day I had another search before uniting them to a black stock, and judge my surprise when I found a princess, with ragged wings, dark abdomen (nearly black), and more like an old worn-out worker than anything else; but undoubtedly a princess. There are very few drones left in the hive. Now what shall I do? Is it too late for fertilisation, or shall I wait another week or two? The swarm hatched a queen, and although there is not yet any signs of brood, still the bees carry pollen freely, and I do not apprehend two sterile queens.—Highgate.

P.S.—I find that by transposing, the black bees receive the Italians peacefully, but have always lost the black bees when trying to strengthen the Italians.

[The hive containing the artificial swarm could not have been properly sheltered from the sun, hence the collapse and fall of its combs. It was, of course, a mistake in any case to transfer the original Ligurian queen, but the presence of the ragged-winged princess doubtless rendered the catastrophe more certain. We should get rid of the latter at all events, and we advise your communicating with Mr. Woodbury, who, we doubt not, will be willing to assist you.]

OUR LETTER BOX.

Chickens Dying (*E. F. W.*).—There is probably some fault in your feeding, as there is no reason why your chickens should die at this time of year. Feed them on bread soaked in milk, dough made of oat or barley-meal. Let them have a grass run, and be well supplied with dust or road grit, also with pure spring water. Keep the hens under the rip till the chickens are seven weeks old. If you do this, we do not believe they will die. You may add to the dietary given above, the knuckle of a leg or shoulder of mutton, cooked and chopped fine. (*C. B. M.*).—Your food is hardly good enough for very young chickens, but it is quite enough to support life, and they should not therefore die. We believe your mistake has been you let the hen out too soon. We never allow our hens their liberty till the chicks are six weeks old, and in the winter use them in confinement longer. We are not very friendly to wheat for small chickens, we prefer barley, but we also give chopped egg; we mix our meal with milk; we also give cooked meat chopped fine. The rips in which the hens are kept should be daily changed in place, so that there is always a fresh roost, and taint is avoided. They want more care and feeding between a fortnight and a month old, than at any other time. Provide them with dust.

Fowls Roosting over an Oven (*Northern Subscriber*).—We should be disposed to attribute the snuffling, which is catarrh or incipient roup, to roosting over the heated oven. All such heat is injurious to poultry. We have enough of change in our climate without inventing any. As we read your query, the fowls also have a roosting place with a brick floor. Nothing can be worse. Find some place where they can roost without artificial heat, and where there is a floor they can scratch upon. If you can do this, all the medicine they will want for a few days will be a stimulant in the shape of toasted bread steeped in strong ale. The heated roosting would be more dangerous in winter than now.

Fowls Suffering from Catarrh (*Constant Reader*).—Your fowls are suffering from very severe cold. It is common at present, and not to be wondered at with frosty nights and unusually hot days. Improve the feeding a little, and while the discharge lasts give two doses daily at the longest intervals, of bread soaked in strong ale.

Game Bantams (*T. M.*).—The cock should be dubbed for exhibition purposes.

Trimming—Names of Judges (*Revd. G. J. Milner*).—The memorial, we believe, was sent to the Committees. The judges' names are pre-published by some Committees; but there are objections to, as well as reasons for, the practice.

Jacobin Pigeons (*Amateur Pigeon Fancier*).—The points of a Jacobin show Pigeon are as follows:—A short beak, the shorter the better; head, tail, flight, rump, and thighs pure white; eye clear pearl; hood compact and long, also the chain; size of the bird small; plumage rich and good, not washed out. The white of the head should not extend below the beak. Shape a little long but neat and elegant. Feed well and wash clean for exhibition.

Introducing a Queen to Hive Containing a Fertile Worker (*J. C.*).—It is too great a risk to attempt the introduction of a valuable queen to a stock in which a fertile worker may be presumed to exist. We should drive and unite to it the inhabitants of a condemned hive.

Removing a Partly-filled Bell-glass (*E. M. M.*).—It should be taken off at all events; and we should appropriate its contents, which cannot but deteriorate by keeping.

Uniting a Swarm and Stock (*M. J. V.*).—The bees of the swarm should be driven into the same hive as those from the old stock as soon as the expulsion of the latter is completed. They will fraternise amicably, and little or no confusion is likely to arise even if they are left until the evening. This delay is, however, better avoided, and they may be at once inducted into their permanent domicile by being knocked out immediately in front of the furnished hive, which should be blocked up an inch or so, and stand upon a cloth spread upon the ground. As soon as nearly all are inside, it should be placed on its floor-board and returned to the old stance. Mr. Payne's plan is unfortunately liable to failure, although it is often entirely successful.

Cooking Indian Maize (*A Subscriber*).—Your maize is ripe very early. As soon as the grains give out a milky fluid when pressed, the cobs can be used. They require then about twenty minutes' boiling, but a week's further growth makes much difference in the time. The common practice is, after spreading butter and a little salt over the grains, to eat them off the cob, when the flavour is supposed to be fully realised; others pick them off with a fork at table. When older, forty-five minutes boiling are not too much.

POULTRY MARKET.—September 8.

It is very difficult to make any quotations for poultry. The supply is moderate, the weather trying, and the trade very small. There is a good average supply of Grouse. Young Partridges are scarce, except very small ones. There are large numbers of these; old ones are also very plentiful.

	s. d	s. d		s. d	s. d

From observations taken near London during the last forty-two years, the average day temperature of the week is 67 7°; and its night temperature 45.3°. The greatest heat was 84°, on the 17th, 1843; and the lowest cold 29°, on the 17th, 1849. The greatest fall of rain was 0.90 inch.

GRAFTING VINES TO PROMOTE HARDINESS.

THE Editors having expressed a wish to know how my Vine grafting succeeded, as far as time will permit I report progress, but still under the impression very much has to be done in Vine culture in this most important direction.

The points kept in view are, with the aid of grafting, to avoid costly Vine houses, and fire heat as much as possible, using sun heat as best and cheapest; to place the most hardy roots in the soil, to endeavour to add to the yearly crops, and to adopt training to poles as practised in the Hop gardens of Kent. Also to improve the size of the berries and bunch, and the flavour, if possible, so that hundreds, possibly thousands, may enjoy many bunches of the queen of all fruits, who at present are excluded not only by the first great outlay, but by the annual cost which is never at an end. I am keeping in view good useful bunches of Grapes, either for the sick chamber or the daily use of a family.

The Vines are all planted inside the house, trained on the rafters only, and there are large squares of 21-oz. glass flaps to open near the ground in front, and at the back close to the ridge of the roof; doors are at each end, glazed to the ground to admit all the sun heat possible. I have only used the common soil of the garden, and no more trouble has been taken than if any other garden crop were about to be planted.

The Vines I am about to mention will only have a small stove inside the house, 4 feet from the front, just to ripen off the fruit at the end of this month, harden the wood, and expel damp and frost. While the Vines are hard at work—that is, are bringing to perfection a good crop, I refresh them with poultry dung, guano, night soil, all in solution in water, as their wants may require.

I have splendid canes, three and four to a Vine—the Vine also with a crop—16 to 20 feet long, and 2¾ inches in girth; joints from 3 to 4½ inches apart, with eyes at this time standing out from the canes like nuts. Now, as to the leaves, I request the Editors to sit in judgment on those I have sent, and pronounce opinion in "our Journal." Several of the bunches hanging will weigh 3½ and 4 lbs.; I have no insects; the lovely shining green of the foliage proves sturdy health; or, could the Vines speak, all would say, "It's just the thing."

I have to remark that after the bearing rods preparing for next year's fruiting had been stopped, one and all broke at the ends with fruit; and in four cases where an eye had burst, that also showed fruit growing out of a green cane of this year's produce. I think this is not very common. Does it not show rather an inclination to perpetual bearing in the Vine?

Lady Downe's grafted on some wild Vines from America, and on the Frankenthal, shows fruit in this way at every break.

Black Tokay, or Alicante, worked on a wild stock, is splendid. A Vine two years from the graft, with four rods 6 feet long trained to poles, showed eighty-three bunches. I have this on the Frankenthal and its own roots. I cannot speak too highly of this Vine.

Gros Guillaume on the wild stock is beautiful; it seems as yet to do better than on the Frankenthal. Permit me to advise not to plant this on its own roots; 5 and 6-lbs. bunches can be grown like Hamburghs, and it is one of the best of keepers.

West's St. Peter's is not satisfactory worked on the Black Hamburgh; I prefer it on the wild stock.

Chaouch makes splendid rods, foliage, and bunches on the wild stock.

Burchardt's Prince, grafted, is very hardy. I like this Vine much; it is a pity it is not more grown.

Foster's White Seedling is also very good under the same treatment.

Trebbiano, or Child of Hale (?), is equally satisfactory under my treatment. I note this, as it is stated in the catalogues to require strong heat. The Vine of Trebbiano has two bunches only; I cut the rest off. The two are good in shape, and will weigh when ripe about 8½ to 9 lbs.

Mrs. Pince's Black Muscat, as Mr. James Douglas observes in page 96, is not a strong grower on its own roots; in fact, I have decided not to plant it in this form. On Lady Downe's it is also doing well with me, but I like much the look of the eyes it is making grafted on Frankenthal. I have grafted it on six other stocks, waiting for advantages if any.

All the Vines I have mentioned have only been planted two years from pots.

I have many other Vines, including all the new introductions, grafted. Fancy has led me to double-work some of these. Possibly I may write at another time. All my friends who have seen the Vines expressed astonishment and admiration.

A word to "Kate," who wrote in No. 433. This house of Vines, of the two wanting more heat than Hamburghs, never was totally closed at night or by day, even during the cold of this spring. At 5 A.M. the thermometer several times stood at 34°, while all the Vines named showed fruit, and they set so well that more than one-half of the berries had to be cut out, and many bunches totally cut off. Another house of Vines, all grafted, will shortly be erected; of the results I may hereafter write.—R. M. W., *Mount Pisgah, near Sheffield.*

[Judging from the specimens sent, your Vines are in wonderful health and vigour. The leaves are perfectly glossy on the upper surface, and their texture is like leather. We shall be obliged by further reports of your results.—Eds.]

AMONG THE ROSES.

Thanks, many thanks, "D," of Deal, for reminding us amateurs, who love the Rose, of the duty which we owe one another. Well may you ask, "Why do not some of our amateur growers give us their experience of the different varieties, mentioning their soils and situations," in order that others may profit thereby? For myself I am heartily ashamed that so many months have elapsed since I occupied a corner of "our Journal" with matters respect-

ing the flower I love so well. I suspect the reason why so few contribute their experience—and the experience of others is useful to the best of us—is the same as that which keeps many good cultivators from competing at our shows—viz., the fear lest what little they can do is sure to be excelled by the doings of others who enter the lists. We all know the results—in the one case a few bold exhibitors carrying off all the prizes from want of a healthy competition; in the other, an eager and earnest seeking, week by week, after Rose articles, and the inevitable disappointment.

What a fortunate rosarian is he whose habitation is upon a Rose soil! Nearly three years ago I came into Warwickshire, and became the tenant of a newly-built house. The garden had never been cultivated, save as a portion of a field; it was full of large and small stones, and so deveid of fertility that hardly anything would grow therein; sand and gravel could be obtained, and can now, at a depth of 2 feet; in fine, it was a sandy waste, only fit for the growth of Potatoes. During my first summer, therefore, my Roses did no good, especially as I possessed nothing but standards, which should be almost entirely discarded from sandy soils. Last year I began with Roses on their own roots and on the Manetti stock, which I planted in well, though freshly, manured ground. A great improvement was the result, even the standards showing their gratitude for the better feeding. During the spring and summer I accumulated a couple of tons of horse manure, which I used for Vegetable Marrows, and in November last, when well rotted, I dug it deeply into my Rose beds, and as I transplanted nearly the whole of my stock I took particular care that the manure should be under as well as around the roots. And what a reward I have had! Since the beginning of May, in spite of the unfavourable weather of the spring, vigorous growth, clean foliage, fine buds, and noble blooms have been the rule, and afforded proof that the disadvantages of a wretchedly poor soil and exposed site (for we are very bleak), may be ameliorated.

Although my standards have done well this season, the Manetti-stocked Roses have done so much better as to make me a convert to the new faith—that the Briar must soon become a thing of the past so far as the true rosarian is concerned. I can understand the repugnance which many old cultivators will have against changing their creed; but I would respectfully submit that although they should not be

"The first by whom the new is tried,"

neither should they be

"The last to cast the old aside,"

for, depend upon it, the Briar is doomed.

Luckily for me, I purchased in November last a lot of Roses on the Manetti stock, and among them was Monsieur Noman. It has delighted me as much as did Alfred Colomb last year at our Birmingham show. Was ever such a pink Rose seen? Your readers will remember the spell which Marie Baumann cast over the Rev. Mr. Radclyffe—how he returned to it time after time with the ardour of a devoted lover; and of such a nature was the fascination which glorious Monsieur Noman exercised over me. I was never tired of looking at its splendid form, and colour, and size, and bringing others to drink of the intoxicating cup. I am afraid, however, that its great beauty departs in the early summer, for I have had no such blooms since. And Alfred Colomb, too—where is its equal for brightness, clearness, and form? It is a class in itself, and, like Charles Lefebvre, will live for ever. Talking about the latter, I must not forget to say that it has done as well with me on a standard as on the Manetti. Perhaps there is no better Rose than this is for all general purposes. Another of my loves is Anna de Diesbach, which was the universal favourite at my house. Even my little children would arrest their gambols to point it out to one another; and a reverend friend of ours was so enchanted with it, that he could only be brought back to his usual frame of mind by my promising that he should possess a similar Rose before Father Christmas paid us another visit. I have been quite disappointed with Charles Rouillard, which does not open well with me, nor does it show any distinct colour. I imagine it requires a stiff soil to bring out the qualities which attract one in the catalogues.

Talking about catalogues, I look in vain for two great favourites of mine—Roses not for exhibition, but to be tenderly regarded in one's own garden. I allude to Queen of the City and Armide. The former grows finely, is compact, well built up, and of a pretty shade of pink. The latter, though rather—only rather—flat, is a charming flower, a free bloomer, and of a rich salmon tint; its foliage is unique, and nearly always keeps in good condition.

Climbing Devoniensis does well; its growth is surprisingly vigorous, its flowers fairly good, and its perfume delicious. Everyone should have this who likes a climber. Will the Comtesse de Jaucourt turn out first or third-class? It has grown and bloomed capitally, yet I cannot become enthusiastic about it. I know those who think it perfection. Another glorious Rose for a soil like mine is Dr. Andry, which has gratified me beyond measure. Do all your readers grow General Washington? If not, let those who wish to have the finest and most brilliant of the autumn bloomers order it at once. Even on a cutting struck last year it has given me a flower to be proud of. Vicomtesse de Vézins is a pink General Washington, and worth a place in every rosery. Elie Morel will turn out a first-class Rose; it is large, has a perfect form, with a charming disposition of its petals. A neighbour of mine has grown such a prodigy on a plant of Hippolyte Flandrin as I never saw before. It is certainly a prime exhibition Rose, though I am of opinion it will require very high feeding. Duchesse de Caylus is a Rose of exquisite form and of fine colour, and it also blooms abundantly; the same remarks will also apply to Abel Grand, a noble Rose. Duc de Wellington is superb in its colouring, and in the duration of its bloom extraordinary; its growth is only moderate. Duc de Rohan I cannot get to bloom properly, yet it is such a fine Rose that I cannot give it up without another trial. I suppose a strong soil suits it best. One of those I could ill spare is the old Duchess of Sutherland; it does equally well on the Manetti, Briar, and on its own roots, and blooms continually and in profusion—in fact, for general good qualities it approaches Charles Lefebvre.

To those who are fond of purples, let me recommend Lady Suffield, which has a luxuriant growth, fine foliage, and large, well-shaped blooms. Madame Fillion, a salmon colour, is a little gem. Marguerite Dombrain suits a light soil, and it is, moreover, a Rose which must be in every collection. Another Margaret—her of St. Amand, I regret to say will not repay me for the trouble which I take to obtain blooms. However, I will give another trial before discarding a Rose which appears in every exhibitor's box. Can anybody speak from experience about Napoléon III.? It grows well enough, though I do not admire the foliage, which is too much like that of the Briar itself; yet for two seasons I have been unable to obtain a single bloom, or even a bud. William Griffiths, although very stiff in its growth, and inclining to raggedness, always bears a first-class flower, which endures for a longer time than any other in my garden. It does well on the Briar.—C. W. M., *Wylde Green*.

PROTECTING GRAPES FROM WASPS.

I have been for several years very much plagued with wasps eating my Grapes. Netting over the ventilators is of little or no use, as my house is old, and consequently there are many little crevices which the wasps soon find out. This year I was recommended by a friend to try tissue paper, and I may say with perfect success, as not a bunch has been touched since it has been put on. It is simple and cheap, and the paper will last for several years if care be taken of it. The way I use it is to take a sheet, or half a sheet, according to the size of the bunch, place it round the bunch, doubling the edges together, and tie it at the top and bottom with a piece of bast. This forms an effectual barrier, and if put on with care, the bloom is very little injured. If the paper be put on when the Grapes are only partly coloured, it does not prevent them from colouring beautifully. I certainly prefer it to muslin.

In a gentleman's garden I saw a more easily applied remedy, but more costly, at first at any rate—namely, an oval, fine wire gauze covering, with a hinge in the centre, a slight catch for a fastening on the opposite side, and a small notch in the top; this was opened and the bunch clasped inside, the shoulder of the bunch holding up the covering. This was of French manufacture. Is it made in England? I understand that bunches kept thus are not liable to damp and mould. Perhaps some of your correspondents have tried them, and can tell if it is the case.—W.

WELLINGTONIA GIGANTEA.

Having read Mr. Robson's remarks, in page 168, on the Wellingtonia, I feel pleasure in stating I have under my care several specimens of this magnificent tree in the most robust

health, and perfect in shape. One is 20 feet in height, 46 feet in the circumference of the branches, and 5 feet 6 inches in that of the trunk, and is a very handsome tree. I hope this favourite tree will retain its position in our parks and pleasure grounds.

I also wish to ask the question, If a plant of Cupressus Lambertiana measuring 39 feet high and 30 feet through the branches, exceeds the usual size?—W. Mayo, *Gardener, Shalstone House, Buckingham.*

APPLICATION OF MANURES.

I see one of your correspondents lays great stress on the necessity of covering manure as soon after it is spread as possible, to prevent its being injured by sun and wind. Many years ago I wrote a paper attacking this mischievous notion, and I think it was published in "our Journal." I call it mischievous, not only because it is erroneous, but because it leads to injurious practice.

I have acres of land now covered with manure as dry as wind and sun can make it, and, of course, according to many persons' ideas such manure is worth but little. If in my place, they would prefer seeing it in an open yard exposed to every shower, or in a heap losing bulk every day, and when rain comes and their land is wet they would cart it on to the ground, spread it, and plough it in immediately. Now, I prefer carting on land when it is dry; when rain comes to soften the land I am glad to be able to set the ploughs to work at once, and am glad the land is already manured. But is not your manure spoilt? some will ask; I would ask, How? What has it lost? Spread evenly over the surface there has been no fermentation, and, consequently, no ammonia has been formed. What has it lost besides water? If the manure is intended to grow a summer crop in dry weather, the moisture in the manure is valuable, but not otherwise. If this very common notion of manure being injured by sun and wind be correct, then guano, the excrement of birds deposited drop by drop under a burning sun, is of no value, the top-dressing of grass land is a most wasteful process, and the manure of sheep is in a great part lost to the farm.—J. R. Pearson, *Chilwell.*

[We somewhat differ from our clever correspondent, but shall be glad to hear the opinions of others who also combine science with practice.—Eds.]

UNSEASONABLE BLOSSOMING.

When staying at Weymouth in the month of June I paid great attention to the state of the fruit crops in that neighbourhood. One day I was much amused, and not a little surprised, to see an orchard, just two miles out of the town, on the Wareham road, in full flower, all the trees, twenty-four in number, being literally a mass of bloom. I first saw it about the 16th of June, and it was not then quite in its full glory; as I passed it nearly every day I took great interest in watching its development, which it reached about the 24th, and by the end of th month had nearly all passed away. The trees appeared to me to be of different kinds, but not of those two late-blooming kinds so largely grown here for cider, the Horner and Chisel Jersey. How they may have set their fruit, or in what condition that now is, I am unable to say; but I shall ask a friend at Weymouth to visit the orchard, and let me know how the crop is, more especially as most other trees in the neighbourhood had their fruit of a considerable size at the time.

Although in many places south and west of us there is but a very poor crop of fruit generally, here we have an abundance, and of good quality. Pears, particularly upon large trees, are a heavy crop. On my young trees I have a fair lot, somewhere from 450 to 500 sorts having fruited. The Quince stocks are especially rich in fruit of fine quality, and the Apples on my Pommier de Paradis stock are a wonder to see.—J. Scott, *Merriott Nurseries, Crewkerne.*

AN ABUNDANT-FLOWERING DEVONIENSIS ROSE.

We have a plant from which we cut from 200 to 250 flowers every year. It was raised from a cutting, and planted-out at the end of a vinery facing due south, and partly sheltered from the north winds by an Orange house. The soil is sandy loam, mixed with old mortar and bricks. We sprinkle a little guano every year round the roots, and with the help of the engine once or twice a-week we keep down green fly, and preserve the plant in a very healthy state. Very little pruning is given, for as soon as the shoots push in spring we are sure there are flowers on them, but a little thinning is practised when they become too crowded.—J. H. S.

BOUQUETS AT THE MANCHESTER SHOW.

As an exhibitor of bouquets, I quite agree with Mr. W. H. Turner respecting the awards of the Judges being final, unless some fraud has been practised; but there was something radically wrong in the exhibition of the bouquets, for all the staging cards were turned topsy-turvy. I came into the tent after the Judges had altered their award from Turner to Yates. I remarked to the Rev. S. R. Hole I could not see what standard they had adopted in judging, as I had two bouquets which must have been overlooked. When he saw them he said, "These two bouquets have been smuggled in since we gave our award, or we should have given them the first prize," and he called the other Judges' attention to them to confirm his opinion, and they coincided with him.

From what I have gleaned since, I believe the Judges were right respecting the smuggling business. If they were not on the table, they were out of sight during the awards being made, and replaced after the decision. It is a pity that any feeling should exist, except an honourable rivalry, at our floral exhibitions.—J. Delamere, *Orton, Cheshire.*

MARÉCHAL NIEL ROSE—BUDDING ON GLOIRE DE DIJON.

In page 180, I see Mr. Harrison Weir has almost given up trying to grow Maréchal Niel. I hope his last attempt may prove more successful, for it is, without doubt, a gem with those who succeed in flowering it. Although I had not seen it growing, and only knew it from cut blooms at exhibitions and notes that appeared from time to time in this Journal, I determined last spring to give it a trial. I ordered two strong plants from a respectable nurseryman, but instead of being strong, they were very poor. From the weakness of the plants I knew they would not bear forcing, accordingly I plunged them in one corner of a Potato frame with a gentle bottom heat, the lights being taken off during fine days. They soon began to grow, made good plants by the end of May, but showed no signs of flowering; so I potted the strongest plant, and let it grow at full length. It has now shoots 8 feet long. The other I cut down, making six cuttings, which have all struck, and are now established plants in 6-inch pots, with strong shoots 4 feet long. One of the cuttings struck produced a flower, and it was a little gem.

After cutting down the weakest of my two plants, it was repotted in an 8-inch pot, and returned to a cold pit, where it remained about three weeks till the young shoots began to appear, when it was turned out of doors, and set among other plants in one corner of the frameyard. There it remained for some weeks, and was soon smothered with green fly, which was syringed off with soot water. Up to this point no flower-buds had appeared, and I began to think it would not flower this season; however, I was mistaken, for shortly afterwards I perceived three very small flower-buds. I removed it at once to a cold pit, where it was regularly syringed, and supplied with liquid manure at every alternate watering. It soon began to swell more buds, and has at present seven fully-expanded flowers, besides several promising buds. It is admired by all who have seen it.—E. Rooker, *The Gardens, Coton Hall.*

Mr. Harrison Weir tells us of his success and non-success. This is as it ought to be. Like him, many have had failures with that gem of Roses Maréchal Niel, and myself among the number. I know of some good plants budded on the Briar, and they produce some fine Roses. I have tried it on its own roots, grafted and budded on the Manetti stock, in pots, and in other ways, but all to no purpose; die the Maréchal would, and did. I had almost given up the hope of ever succeeding; but as I did not like to be deprived of the Maréchal's company I thought I would try him again budded on Gloire de Dijon. It proved a first-rate union, and during the past summer I have been rewarded with yellow Roses as large as Jules Margottin and of great substance, the colour being exquisite, and the

perfume all that could be desired. I think Gloire de Dijon will be a good stock for the Maréchal. I have this season budded it on Souvenir de Malmaison and other Roses. The buds have taken, but I must wait the result.—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

ROYAL HORTICULTURAL SOCIETY.

FRUIT COMMITTEE.

An adjourned meeting of this Committee was held at Chiswick on the 9th inst., when the collection of Potatoes, which was reserved from last meeting, was submitted to the Committee, after having been cooked.

Mr. Nash, Threehouseholds, near Slough, sent four varieties—White Blossom was close, waxy, and very inferior in quality; Myatt's Ashleat, very excellent; Prince of Wales boils floury, but is deficient in flavour; Early Rose boils white and floury, but has a very objectionable flavour.

Mr. Headley, of Stapleton, sent a seedling Kidney Potato of medium size and good form; when cooked it is of rather a deep yellow, very floury, and possesses an excellent flavour.

Mr. Fryer, of Chatteris, sent Rough Red, which is a fine-flavoured and floury Potato; but a great objection to it is being so deep in the eye, necessitating so much waste in peeling.

Mr. Walton, gardener to E. Pottle, Esq., sent a seedling, called Walton's Late Kidney. It is a fine-looking Potato, but was not ripe; the flavour was excellent even then.

Messrs. J. Carter & Co., Holborn, sent Early Rose Potato. These, like those sent by Mr. Nash, boiled white and floury, but they, too, had the same objectionable and disagreeable flavour. In the opinion of the Committee, this is an inferior Potato for table use.

Messrs. Stuart & Co., of Nice, sent a seedling Melon, called Triomphe de Nice—a large, round, yellow, prominently-netted, green-fleshed fruit, with great thickness of flesh, and with a rich flavour and fine aroma. It was awarded a first-class certificate.

ADULTERATION OF SEEDS BILL.

In continuation of our extract respecting garden seeds from the blue book relative to this Bill, we give this week the

EVIDENCE OF MR. DANIEL NASH.

Mr. Shaw-Lefevre.—You are a partner in the firm of Minier, Nash, & Nash, seedsmen of London?—Yes, of the Strand.

Have you for many years been engaged in the seed trade?—Yes, upwards of forty years.

Has your business been mostly of a wholesale character?—Mostly wholesale; but we have done retail.

And you have paid some attention to the question now before the Committee?—Yes, I have given it the best attention in my power.

And in the end of June last you presented a memorial to the Board of Trade against certain clauses of this Bill?—I did, inasmuch as I thought that the form of the Bill was such that it would create the utmost possible confusion in the trade, and that there would be an enormous amount of difficulty in any person wanting to swear that such-and-such seeds had a proportion of adulterated seed amongst them, although if you were to see a sample, in bulk, of killed Turnip seed, or adulterated Clover seed, you would say, "Yes, that is adulterated."

I apprehend that what you wish to say is this, as regards adulteration, that though in bulk it is very easy to tell whether the seeds have been doctored or have been killed by the process that we have heard of, yet, when the killed seeds are mixed in small quantities with genuine seeds, it is exceedingly difficult to tell their presence?—I would hardly say that it is easy to tell it in bulk: in some kinds they do it so nicely: I consider that in some cases it is almost impossible for a person to say on examination whether there is seed which has been killed to represent Turnip seed, or coloured Trefoil to represent Clover; when it is mixed in the bulk in the small proportion that is put in, I think it would be impossible for any one to go into the witness-box and swear that there was any killed or coloured seed.

You consider that if the Bill passed in its present form there would be considerable danger of injustice to the sellers of seeds on the ground that complaints would be trumped up against them, and charges produced without just cause?—Yes: it was on those grounds that I took the liberty of writing a letter to the Board of Trade stating that I thought I might give some hints that would make the Bill more effective; I was particularly anxious to have a Bill for doing away with the adulteration of seeds; it was done, no doubt, originally, to get something like a fair average growth, for seeds vary very much in one year as compared with another: I have known the germinating power of them to be in one year 40, and the next year 80 per cent.

You are now speaking of the process of mixing old and new seeds together?—I am speaking of mixing killed seeds particularly: I do not think it is possible for a man to say with certainty that the seed is adulterated with killed or coloured seed.

You agree with previous witnesses, that the custom of mixing killed seeds has existed of late years to some extent?—Yes.

In your opinion, is the practice as prevalent as it was or not?—I do not think it is; I think that there has been a general improvement in the trade, and I think that now, though there are cheap sellers, no doubt, as in all trades, if you take the great bulk of the trade, seeds are sent out now in the ordinary way very much better than they were twenty years ago.

Have you found any difficulty yourself in buying pure samples of seed?—We have our seeds grown for us expressly.

I think you grow them under contract?—We grow them by contract; I do not do much in Clover seed; I sell pounds where some of the large Borough houses would sell tons: that is their trade.

Do you deal in Turnip seed largely?—Very largely.

Then you can speak with reference to that class of seed?—Yes; and I think there is considerable difficulty in saying, and it would be almost an impossibility to say, that such-and-such seed was adulterated with killed seed; killed seed and old seed come so close.

Has there been, in your knowledge, a considerable mixture of old seed with recent genuine seed for the purpose of adulteration?—I will not say that it is for the purpose of adulteration; but it is a common practice to mix old seed with new seed; and for this reason, that we cannot get an average growth without resorting very frequently to the seed of the previous year, or the year before that.

Therefore, in consequence of that, in a bad harvest, you are obliged to mix one-year-old, or two-year-old, seed with the new seed for the purpose of increasing the average, and, I suppose, sometimes you reduce the average by the same process?—Yes, that is precisely the way in which the thing got into use at first: our invariable practice is to test the growth of any seed of any importance when it comes in, and if the seed is beyond what you may call a fair average growth of its year, then you bring it down.

By mixing with it old seed?—By mixing with it either old seed or killed seed, as the case may be; but if, on the contrary, it is below what you consider the average, you resort to the seed which you have in hand; if we have had two consecutive bad years for Carrot seed, say, as you cannot make Carrot seed, or buy it, you must take it as it comes; then it is the custom of the trade to say that it would be necessary to sow such-and-such a seed "thicker than usual," or "much thicker than usual;" the great object of the trade is to keep their seeds as nearly as they can at one average growth.

Can you tell us what that average growth is?—It varies very much in different varieties.

Take the case of Turnip?—It will grow from 80 to 90 per cent.

Mr. Pell.—Is that Swede?—Swede or White Turnip; taking the average of seven years, I think that Onions at the extreme would not grow more than 60 per cent.; we endeavour to get that. Take the case of Broccoli and Cabbage; they come about the same as Turnip seed, not quite so much; then look at Cauliflower, that is an article that ripens very late, generally in the month of September. Last year Cauliflower up to the month of August looked one of the most promising crops I ever knew, but whether from heat or drought that seed generally collapsed, and what little was saved was of such inferior growth that it was good for nothing virtually; you have to take that, therefore, off your average of seven years: I say that Cauliflower will not average 50 per cent.; Mr. Murray said that different seeds varied very much in their growth, and there is no doubt of that.

Then I understand from you that it has been the custom of your trade to mix the seeds of several years together in order to produce an average germinating power?—Yes.

And that in some cases that has been arrived at by mixing killed seeds with genuine seeds?—Yes.

But you think that that process is not carried out to the same extent as it used to be?—I think that, taking the larger amount of seed sold there is no doubt that there is a larger quantity of seed killed, but then the increase in the sale of Turnip and Mangold Wurtzel seed has been enormous for the last twenty years.

Do you think that the average standard of germinating power during the last few years has been lowered or not?—I think it has been increased.

Then you signed this memorial to the Board of Trade on the ground that you considered that the Bill, as it now stands, would subject the sellers of the seeds to possible persecution?—I did. Might I be allowed to state that, in the first instance, I had drawn out that memorial, and intended only to strike out clauses 1 and 5, and have nothing to do with the importation of seed, but I conversed with some gentlemen at Mark Lane one Monday, the very gentlemen who have their names down as Promoters of the Bill, and who have since said that they signed that memorial under a certain restraint as it were, and I put that clause referring to importing killed or dyed seeds in, in order to meet their objections as far as I could, not that I thought it of much value; I wished to do away with the killing of seeds.

You wished to confine the Bill to the prevention of killing?—Yes, killing and dyeing.

And not to touch the seller of seeds, on the ground that it would not be possible in evidence to prove with certainty whether killed seed or naturally dead seed had been mixed in the sample?—That is precisely what I wish to state.

Dr. Playfair.—What is the great advantage of obtaining an average?—That farmers and market gardeners should have no difficulty in getting what you may term an average crop.

Do the farmers attach very much value to that average?—I do not suppose that they even know it.

Supposing that there is a great advantage in obtaining that average,

where is the disadvantage in the employment of killed seed to produce that average?—I do not think there is any disadvantage whatever.

Then why would you legislate against killed seed and not legislate against reducing the average by old or naturally dead seed?—I do not think that that is in the clause at all.

This clause is confined to killed seed?—Yes.

But where is the disadvantage to the farmer if he wishes to produce a general average of using the killed seed for that purpose?—It is a disagreeable practice, no doubt of it, although it is attended with convenience; I myself detest it.

What is the difference to the farmer between using killed seed to reduce seed of 90 per cent. to 75 per cent., and using old seed to reduce it to 75 per cent.?—No difference.

Then if the killed seed produce no disadvantage to the farmer, why legislate against it?—I consider it to be a disagreeable practice, and I would rather see it done away with.

But you would still, as a seedsman, allow yourself to mix bad seed with good, to reduce it to an average?—I would not say bad seed, but old seed; there are individuals who wish to sell, and parties who wish to buy cheap, and below what you may call a fair market price, and it gives these parties an opportunity, by reducing that seed, instead of sending it out at 75, to send it out at 50 per cent.; I want to put a stop to that kind of thing, and to have the trade carried on in a more legitimate way.

Would you have an objection to warranting the standard of germinating power with regard to different seeds?—I do not think it can be carried out; so much depends on those who test seed, the soil it is tried in, and the attention that is paid to it. If a man puts a little too much water, it may turn some seeds into a jelly. It is men, whose business it is to try these seeds, who will do it with accuracy; it may answer all the purposes which a farmer may require to put the seed in a flower pot, and I wish that every farmer would do so.

To whose advantage is this Act to be, to that of the farmer or to that of the seller of the seed?—I do not know that it is a particular advantage to either one or the other: I believe one thing, that the farmer gets now regularity of crops; I believe that under a different system, in some seasons, when there have been two successive failures, he would get a very inferior growth; he does not pay for his seed now what he would do if he had it to grow 100 per cent.

But will he derive any more advantage if an Act is passed to prevent killed seed being used for the purpose of reduction, than he does now, because you may use inferior seed for the purposes of reduction, may you not?—You may do it, certainly.

We are supposing that this Act is for the benefit of the farmer, do you see any likelihood of the farmer obtaining any such advantage?—I think it would be decidedly in his favour; that he would get seed of a larger growth than he does now, upon an average.

But I thought you said the object of seed-sellers was to reduce the seed to a general average by mixing the seed?—That is the object, no doubt; the farmer would otherwise get for two or three years consecutively, perhaps, a good growth, and then for two or three years a bad growth.

Do you think that he would get true net seed, unmixed with inferior seed, if this Act were passed?—I think that he would get old seed mixed with the newer.

Seed producing a general average?—Yes.

Then I do not see where the farmer is to obtain much advantage?—Not a very considerable advantage, I do not think he would; I say that the practice of using killed seed is a nasty practice.

But does the killed seed in the slightest degree interfere with the vitality of the other seed?—Not in the slightest.

Where then is the disadvantage to the farmer of getting the same average by killed seed as by seed of an inferior growth, supposing you reduce it to 75 per cent. in both cases?—There is not the slightest difference.

Mr. Cross.—You sell both wholesale and retail?—I do.

Do you ever sell seeds, what they call net?—Yes.

When is it you sell seeds net?—Where they inquire of the travellers for it. It is well known that seeds are sent out in the ordinary way, what you may term a fair average growth, and of course every man who has been in the trade knows that in some years seeds will grow much better than in others, and he trusts to the seedsman he deals with to send him a fair average quality; but if that man had stock on hand below an average growth, he would say "Mr. Nash, will you send me an extra quality, and I will pay an extra price for it?"

When the retail dealer has some old seed he wants to improve, he asks for net seed?—Yes.

But do you ever sell net seed under any circumstances as net seed?—Not unless they pay a different price.

Do you ever sell net seed to a retail man?—Yes.

If I were to write up from the country for Turnip seed, would you send me net or adulterated?—I would send net as a rule; I might not send you all new seed.

But no killed seed?—No killed seed; it is always net seed in Turnip seed that we send out to private gentlemen.

But not to the retail dealer?—No.

But why am I not to have the benefit, as a private gentleman, of the average growth, as well as the farmer?—You would have it.

Then (to put it in another way) why should not the farmer have the same benefit of average growth as I have?—If the farmer applied to me he would get it; but the farmer does not apply to me.

Will you tell me where is the injustice you speak of in this Bill; you say that it would be unjust, do you not?—Unjust with regard to charges that might be made against individuals for selling seed that was adulterated.

Supposing a charge was made, and the case not made out, what injury would happen then?—You cannot go before a magistrate without having your name paraded in the country newspapers; and people naturally say, "Where there is smoke there is fire," and it would be exceedingly annoying to be taken down to Cornwall, say, with your books, to prove that that seed was as you imported it.

You would rather keep away from the magistrate altogether?—Yes.

You say that your great object in the seed trade is to give a fair average growth?—Yes.

In Turnip seed you put that at 80 and 90 per cent.?—Taking this year I should question if it would come to that.

At all events your object is to put it down to the very minimum average growth, that is to say, to make it as much adulterated as you can?—You can more easily do that than the other way; you can carry on your business more conveniently in that way; you cannot increase your growth, but you can decrease it.

Supposing that there is an increase of growth in any one year, does not that make a difference in the mixture you put in?—Yes.

But if there were a small quantity of good growth in one year you would still adulterate it, in order to meet the demand?—If there were a small quantity of good seed, you would have to spread it all over the country.

But it would never enter your head to say that the growth of seed was so small one year that you could not meet the demand?—Yes; if all new seed was required, sometimes, if you were to give gold, you could not have it.

Do you, as a matter of practice, ever give out that you have no seed?—No; because I can generally get it from a trader if I have not got it myself.

If there is a deficiency in the growth of one year, is it not the practice of the trade to make it more plentiful by reducing it with the seed of old years?—No, that has not been so to my knowledge, because of seed that will grow for three or four years there is generally a pretty good stock.

Now, you stated that you wanted to mend this Bill. Will you tell us how you want to mend the Bill?—The memorial which I drew out, and which has been read to you, expresses my view; I gave to each party who attended the meeting a copy of it. I want to make clause 7 run thus:—"Whosoever shall be convicted of killing or dyeing seed, or knowingly shall import killed or dyed seed, shall for every such offence," &c.

All you want to affect by the Bill is the actual killing of the seed, or dyeing it, or importing killed or dyed seed?—Yes.

Dr. Lyon Playfair has asked you several questions on this point, why is it better for the farmer that killed seed should be prohibited than old worthless seed. Can you say why?—I do not think that it would be any better.

But you have also said that if killed seed were not allowed to be used, old seed would certainly be used, in order to keep up the average growth?—It would, so long as old seed existed.

Then I want to know, as Dr. Lyon Playfair wanted to know, what would be the benefit which the farmer would get from killed seed being prohibited?—Between using killed and old seed, I do not think that there would be any benefit at first.

When would he get benefit?—Perhaps some years hence, when the old stock is exhausted.

In your opinion there is a great quantity of old seed still in the country?—Of some sorts; I think that there is a very small stock of Turnip seed; of other seeds there is a relatively large stock.

And in your opinion it is just as injurious to the farmer to have this old worthless seed mixed up as killed seed?—Yes.

Do not you think, therefore, that in the first clause of this Bill words should be introduced to prohibit the mixing of old worthless seed, as well as killed seed?—Where are you to draw the line?

Old worthless seed, practically dead seed, I mean?—Well, I do not think you would get such a thing; they will not allow it to get dead.

Inferior seed, seed of 5 or 10 or 15 per cent. growth?—There is virtually no great difference whether a man uses that or uses killed seed.

Dr. Playfair.—Is it not a fact that the qualities of seed are continually varying according to the harvest, and the climate, and the conditions of growth?—Undoubtedly so.

Then is it not the fact that there will always be inferior seed which you can use to mix with the superior seed? It is not the question of using up of old stock, but is it not the fact that inferior seed will constantly be grown under varying conditions of climate and of harvest?—Undoubtedly.

Then the farmer still might have the seed, whether for his benefit or not, reduced to an average by that inferior seed being used to mix with the superior, even though the old stock were exhausted?—Yes.

And different places in the same year may produce seeds of different growth?—Yes, more especially upon heavy lands; last year upon heavy lands Onion seed grew better than I ever knew it in my life, 90 and 95 per cent. This year, in all probability, the seed will not ripen till the month of October, when we often get autumn frost, and it may not grow 26 per cent.

And you would use that seed to mix with the higher quality?—We should use the last year's growth to mix with that if we could do it.

Mr. Cross.—If I, as a private gentleman, were to write to you an order for Turnip seed I should get net seed, I understand you to say?—Yes, at least, no killed seed with it.

If I were to write to an ordinary seedsman in the same town specifying that I wanted some of your seed, I should get mixed seed?—Most probably.

Dr. Playfair.—Your interpretation of net seed is not seed of that year's growth, but unadulterated seed of a certain average?—I would not say of a certain average.

It may be superior mixed with inferior, or inferior mixed with superior?—Yes.

Mr. Cross.—But I should get a different class of seed if I went to you direct from what I should get if I went to one of your retail customers?—You might for one year, but I do not think that you would for seven years together.

Dr. Playfair.—Why do you take seven years?—I take seven years as a fair datum to go upon, but you might take fourteen, if it were preferred.

Mr. M'Lagan.—Did I rightly understand you to say, that you do not mix to increase the germinating power of the seeds, but always to decrease it?—Most certainly not. If the seed this year is bad, and last year's seed is good, we mix to increase; we keep the best growth for that very purpose in case of a failure or depreciated growth in the next year.

You said that it was immaterial to the farmer whether killed seed or old seed was mixed to bring the growth of the seed to the average?—If a man gets seed to grow, say, 75 per cent., and if we know that for all ordinary purposes it will give him a good average crop, I cannot see what difference it makes to the farmer whether that seed is mixed with killed seed or with seed of an inferior growth.

Supposing that it is mixed with killed seed first, that seed is warranted not to grow, therefore the farmer will not expect to see a plant from it?—It is not warranted.

You do not expect that killed seed to grow?—No; I should be sorry to see it grow.

If you substitute old seed for that killed seed, that old seed may be several years of age, and as seed gets older it is longer in germination, is it not?—Not very materially.

Do you mean that three-years-old seed will germinate in the same time as one-year-old seed?—No, but two-year-old seed and three-year-old seed will not differ much in that respect.

Between ten year-old seed and two-year-old seed will there be much difference?—If you go to those long dates, you would treat it as dead altogether; you would not take into consideration the growth of that seed.

How many years would you go down to?—It would depend on how the seeds were ripened; I have known Mangold Wurtzel grow well when it was a dozen years old, and Broccoli.

If you sold new seed mixed with old seed of different years, you would have an irregular braird, would you not?—Yes.

Is not that irregular braird a disadvantage to the farmer?—It would be, possibly; but if you could have your field as level as this floor, and if you could get your drill to go in the same depth, you would get a regular braird. In the same season you may see a long row of Mangold Wurtzel without a miss in the plant, and in the same row you may also see several yards with scarcely a plant, from the drill going deeper into the soil.

Take the case of a farmer having his land in the best condition, and the weather as favourable as possible, and supposing that he sows there some of that new seed mixed with old, and after a while an irregular braird comes up, do you think that an advantage for a farmer?—I think the seedsman who knows his business will take care that he shall have seed where there is no material difference in time.

How could you do that?—There is not more than two days' difference between good Turnip seed, one, two, and three years old.

Take it seven years old?—You seldom get that.

I think you said in your evidence that you do not object at all to mixing seed of different quality?—I do not.

But what you object to is the killing of the seed; you want to do away with that?—Yes.

Supposing that this Bill should pass, and that you stamped out old seed altogether, and that you want still to reduce your germinating power of seed to a certain standard, where will you get a sufficient quantity of old seed in the country to do it?—I do not at all know; I think that when the old stock of seed was exhausted there would be an end of the matter.

Then you think that the effect of this Bill would be to do away with having large quantities of old seed on hand?—I think it will, so far as killed seed is concerned.

In fact, whether you introduce old seed or not into the Bill, you will do away with the use of old seed through doing away with killed seed?—I think that it will get used up.

And consequently you think that the effect of this Bill will be to do away with mixing altogether?—It cannot do away with it. If we were not to keep an old stock, sometimes the country would be bare.

As I understand you, there is a large quantity of killed seed mixed and sold at the present time?—Yes.

By the Bill you do away with that, and therefore you withdraw from the market a very large quantity of seed?—Yes.

That being the case, old seed would have to be substituted for a few years for that killed seed?—Yes.

And afterwards, what seed would you have for mixing?—No seed at all, it would all go away as received from the growers.

You would do away with mixing?—You might have an excess in some years; Yes. In 1868 you send out what you want to come in in 1869. You may "calculate on getting from that 24 bushels an acre," and instead of doing so you may get 40 bushels an acre. The same thing may apply in the following year. Then you get an excess for your demand.

I think you have admitted in your evidence already that there is very little stock of old Turnip seed in hand?—I think there is very little.

And consequently the passing of this Bill would do away with the mixing at all of any old seed, even with Turnip seed?—It would in a year or two.

If the Bill should pass, and killed seed should be withdrawn from the market altogether, would you still have the mixing carried on?—You must do it; you cannot carry on the trade otherwise. Very often you do not get enough seed of one year's growth, not half or a fourth enough, to supply the wants of the country.

Would you be able to arrive at your standard as easily by mixing the new seed with old seed as by mixing it with killed seed?—Yes; there would be no difficulty about that. We always have our regular test every autumn.

And how often do you test?—Always in the autumn; and if we have any doubts about it at all we test again in the spring.

That is after you have mixed the seed?—That does not follow at all; probably it is before.

Then do you test both your new seed and your old seed in the autumn and the spring?—Not always in the spring; we test them when they come in, and if there is anything we have left over, we always test that; and if there is anything doubtful in regard to our growers as to the seed tested in 1868, before we send that seed out in the spring, we have it re-tried.

Then you admit that seed is very apt to lose some germinating power in six months, that is to say, from autumn to spring?—Yes; it very often does.

Still you scarcely admit that it will lose much germinating power in the same number of years?—It depends upon how it has ripened; take late-ripening seeds, like Radish seed: I knew seed the growth of 1868 thrashed the same autumn, which grew very fair when it came in, but in the following spring it grew very badly. So much depends upon how they ripened, and fifty different things. You may get a heavy frost in the month of October: that seed does not show it very much at the time, but it does show it after you have kept it three or four or five months.

After two years have passed, and you have a supply of old seed in your stores, do you keep all the different years' growth separate?—Not always.

They become mixed after a year or two?—They become mixed of necessity in this way, that you have mixed two already, and have not sold all of that mixture.

You always have a quantity of old seeds about you?—Of some kinds.

Say of Turnip seed?—We have a very small quantity of that now.

But in previous years had you always a small quantity?—No; sometimes we had a very large stock. If the seed comes down very low, you buy two years' consumption. I once knew seed to be worth 50s. a bushel, and the next year it was bought for 7s.

Now you have admitted that you generally mix seeds to bring them to a certain standard?—Yes.

Having admitted that, do you see any difficulty in selling your seeds according to that standard; I mean in warranting them at that standard when you sell them?—I think that there is a great difficulty in that, because I would not rely upon people making a proper test.

There is your own test to put against theirs. That would be taken in evidence against their test, would it not?—I can give you no other reason than that of the difficulty of testing.

But you test yourself?—I test myself.

And you sell it according to your test?—I would not guarantee it; I could be prepared to prove that, according to my test, it grew so-and-so; but I cannot make other people bring out the same result.

Do you keep samples of all the seeds that you sell?—For a certain time.

Suppose that a complaint came in that some seeds which you had sold did not come up to the standard, would you not say that you were quite ready to test it?—Most certainly.

What difficulty, then, would there be in guaranteeing it?—That is another thing. I could not be certain that a man would use proper discretion in sowing that seed and growing it. One man will get a crop from seed, and another will get a total failure with seed out of the same bag sown on the same day. I have this from a market gardener within a fortnight with regard to Carrot seed; and that is one of the most difficult seeds we have to manage. He said that he was not going to drill it: I said, "Why not?" He said, "Because last year he had almost a total failure in that which was drilled, and just where it happened to be on the headlands and to be trodden down it came as thick as grass." He said, "If it had not been that I saw it grow, as it did, on the headlands I should have believed that all the seed which you gave me was bad."

I am supposing that you sell guaranteed seed according to your own test; would you object to that?—I could not guarantee it. How

could I guarantee it? I could only say that, according to my books, my seed would grow so-and-so; but I would not guarantee for you to make it grow. Ask any gentleman's gardener how he makes seed grow one time and not another. Give half-a-dozen people samples out of one lot of seed, and I have no hesitation in saying that you will find a difference of 10 or 15 per cent., according to the different seeds that are sown from the same sample. It is a most difficult thing, and the seed trade is one of the most difficult trades that I know.

Mr. Cogan.—Do you believe that it is difficult to distinguish artificially killed Turnip seed from Turnip seed that has become naturally dead?—I think that it is, to a great extent. Seed may get a nasty sweat on the barn floors. That is where it is more injured than in any other way; particularly where large quantities of Turnip seed are grown and they have very little barn room, that seed does get damaged more in that way than in any other. If you go to Romney Marsh, there are hundreds, and, perhaps thousands, of acres grown, and in that whole district you hardly see a barn.

By crushing, is it not possible to distinguish artificially killed seed from naturally dead seed?—I do not think that you can distinguish it with a certainty; I think that you may get a pretty fair idea of it, but not to distinguish it with certainty.

Have you tried that as a test yourself?—Yes.

Do you use it as a test of the seeds that you buy?—I cannot say that I do, for I never have any doubt of them; I not think that the growers that we deal with would be likely to have any killed seed to mix with it.

Are the seeds that you sell exclusively seeds that you buy from the growers, or do you buy killed seeds and mix them with the other seeds?—I have admitted that fact, that we do it to reduce the average sometimes.

You think that it is difficult to distinguish the artificially killed from the naturally dead?—I do; in regard to Clover seed, I may say that I am not much in the Clover seed trade, but I think that if you get a small sample of what is called Red Clover of foreign growth, a great many of those seeds are exceedingly small and scarcely any larger than Trefoil seed, and a person's eyes must be much better than mine to tell the difference; and then what man on earth can tell whether White Clover is adulterated by looking at it, when only a small per-centage of coloured is used?

Mr. Pell.—Did I rightly understand you to say that it is the practice of the trade to sell all the seed as near as possible with one average germinating power?—That is my practice, and I believe it is the practice of other houses.

And that that is done for expediency, in order that the farmer or gardener may know about what to expect from the seed that is furnished to him?—Most decidedly.

And, so far as the matter of expediency goes, you would not object to have some old or killed seed in order to reduce some very good seed down to the standard?—That is my present system.

You know something about seed-growing yourself; does not the amount of germinating seed in any sample depend very much upon the way in which the seed is dressed?—Yes.

Would it not be possible to dress inferior seed up to a sample, as well as to tone good seed down to a sample?—Not altogether.

Nearly so?—Not in an unfavourable season.

Is it not the practice in the growth of Turnip seed, that when they are dressing, there are two samples made of it—namely, the head which is the very best, and then the next quality which would have vitality in it, but not to the same amount as the head?—No; I think that you are erroneously informed there.

I have grown several hundredweight of it myself. You do not think that it could be as well dressed up?—You could not improve that by dressing 5 per cent., I should think.

I want to know whether it would not be possible by giving extra dressing to the seed in a bad year to bring it up to the standard, instead of doing what is the practice of the trade—namely, reducing the seed down to a sample?—No; it must be in a very extreme case indeed that that could occur. It could only be where seed was very much blighted; then you might, by extra dressing, bring it up to a better growth. But you can never make a bad sample grow well.

Then, putting honesty out of the question, and going to expediency and practice, it would hardly be possible, without killed seed, to sell stock that should average 75 per cent.?—I do not think it would.

What would the trade do, supposing that this Bill became law, when they were deprived of those means of bringing their seed down to a particular standard?—I think that there would be a certain amount of inconvenience; the farmer at some time would get much thicker crops than at others.

Then though you are against the morals of the practice, you think that there is some expediency in it?—There is some expediency in it.

Mr. Brand.—I understand you to say that speaking as a seed merchant, you are anxious for legislation on this question in the seed trade?—In the first instance, I did not think legislation necessary. I thought that the trade had worked very well for a great many years, and that those who sold a good article had retained their customers.

But on second thoughts you have come round to the view that it would be desirable to legislate on the subject?—The view that I take is this, that there has been so much said about it, and that so many questions might arise, that I should rather have the operation completely taken out of our hands by making it penal to kill or colour seeds.

Several questions have been asked you with regard to the interest of the farmers in this matter; I presume that the farmers are very much like other people in this respect, that when they buy an article they wish to have it genuine?—Yes.

There are two ways of toning down seed, one is by introducing killed seed, and the other by introducing old or dead seed?—Yes.

The supply of killed seed is almost without limit, is it not?—Yes.

But the supply of old seed is comparatively small?—Yes.

And you as a seed merchant, are very anxious to reduce as much as you can the supply of old seed in your warehouse, I presume?—Yes, I am.

And therefore in the course of a short time, if this Bill were passed, and the supply of killed seed were stopped, you would have very little old seed to fall back upon?—Very little.

Chairman.—I think that you were formerly a miller at Biggleswade? No, but my father was.

You yourself have been in the seed trade for forty years, you have told us?—Yes.

And for twenty-one years of that time you have been chairman of the trade association?—Yes.

Do you remember receiving a letter from Mr. Sharpe, of Sleaford, addressed to you, urging upon the trade that it was time to abandon the system of adulteration now in practice?—I do.

And I think in consequence of that a meeting of certain members of the trade was called, you being one of them?—Yes.

And his proposition was favourably entertained?—Well, we heard what he had to say.

And you agreed with him generally in the expediency of putting an end to the system of adulteration?—Not at that time.

The meeting was adjourned to lay it more generally before the trade?—The meeting was adjourned to the 22nd of June.

By way of laying his proposals before the whole of the London trade?—Yes.

And when the 22nd of June came you were the chairman of the meeting, I think?—Yes.

I think a resolution was then passed condemning the use of killed seed?—Yes; the minute of that was to this effect: "The Committee have become aware, in their investigations, that a system has been carried on which they consider prejudicial to the interests of the seed trade, and recommend that every means should be used to prevent further use of prepared seed for adulteration."

And it is very much on the proceedings of that meeting that the present Bill has been introduced into Parliament?—Well, I cannot say that: I must tell you very candidly that I have told Mr. Sharpe more than one or twice that I did not think the project would be carried out with any probability of success.

Mr. Brand.—Did you approve of that resolution to which you have referred?—Yes.

You were chairman of the meeting?—Yes.

You did not express any dissent?—It was the sense of the meeting, and I approved of it to that extent.

Chairman.—You have told us candidly that it has been your practice during the whole of the time that you have been in business, to reduce your seeds down to a certain growth?—Yes.

That is, in other words, to adulterate them?—Yes.

Have you continued that practice up to this season?—I have.

Using killed seeds, or simply inferior seeds?—Principally the lower class seed; but I have used killed seed too.

Nevertheless, I think that you told the honourable member for South-west Lancashire, that if a customer wrote to you for seed, without giving any special orders, you would send him net seed?—I said a private customer.

Then you draw a distinction between a private customer and a customer in the trade?—Yes.

If a customer in the trade had written to you, without giving special instructions, you would have sent him seed which the trade term "seed as the trade use it?"—Yes; seed of the average growth and quality.

That average being in some cases reduced by the use of killed seed?—Yes.

What should you say would be about the average which you generally used, about 75 per cent.?—About 75 for some sorts. For some sorts you cannot get that average. Mangold, I suppose, would be 100 per cent.

If the retail dealer wished to buy net seed of you, he would not get it unless he specially stated that he wished it?—No.

Are you aware whether Melon seed is ever adulterated?—It would not be worth while. All the Melon seed that you would sell would not be more than two or three pounds a-year. I can answer the question so far that I never knew it killed.

I suppose that you consider that selling to the retailer in the way in which you have mentioned is scarcely a fraud, inasmuch as it is the recognised custom of the trade, and the dealer would be able to a certain extent, by his own knowledge, to protect himself?—Unquestionably so.

Are you of opinion that the retail dealers as a rule have a sufficient knowledge to be able to distinguish pure seed from adulterated?—Only by trial; proof of growth.

And with regard to trial, they have no special advantages over the farmer or the eventual consumer of the seed?—A great number of the seedsmen who use it are nurserymen who have every advantage, hot-houses, and so on.

A great many are grocers, and ironmongers, and so on?—But that chiefly applies to the Clover trade; it does not apply so much to our trade.

You have said that you have been in the habit of mixing your seed

simply for the purpose of making it an average growth?—Yes, from no other motive whatever.

It has had nothing to do with the profit to be gained by it?—Not a bit.

We have had it stated in evidence by one witness that there is no profit to the dealer by the adulteration; and by another witness, that the profit sometimes runs up to 300 per cent. You agree with the former witness?—Most certainly. The other witness must have meant, when he spoke of 300 per cent., some little trivial thing; because, in anything like wholesale transactions, we know nothing of that per-centage. He must have meant something like Melon seed, which is worth a guinea an ounce.

Then I think I understand from your evidence, that you would be in favour of a Bill for preventing the killing of seeds only?—Killing and colouring.

But that anything beyond that you consider would create such a confusion in the trade that it would be inexpedient and inadvisable?—I think so.

I imagine that, in that answer, you are considering simply the interest of the trade, and not the interest of the public, that is to say, of the consumer?—What would be to the interest of one would almost be to the interest of the other. I think that there might be some cases where people who were disposed to be litigious, or who wanted to back out of a transaction, might take advantage of the Bill to do so; for instance, if a man bought Clover seed, and the market varied 5*s.* on a single market, as it does sometimes, he might have an opportunity of repudiating that seed by saying, "Oh, your seed is adulterated." He might buy Mustard seed of me, for instance (these seeds are generally bought by small sample in Mark Lane, of half-a-pint to a pint), and looking at it afterwards, when the price had changed, he might say, "Oh, your seed has some Charlock in it, and I shall go before a magistrate if you do not let me off the bargain, and say that it is adulterated."

Would not the introduction of a clause that the information must be laid within a certain time obviate a difficulty of that sort?—He could do it in less than a week. I have known Mustard seed vary 5*s.* on a market day.

Still, all that is in the interest of the dealer that you are now speaking of?—More in the interest of the trade than anything else.

Can it be in the interest of the public by any possibility?—I do not know that it can.

Mr. Shaw-Lefevre.—You told us that in some seeds the growth varies very much from year to year?—Yes.

And you mentioned that in Onions there was a variation from 21 per cent. to 96?—Yes.

Supposing that you have grown, under contract with some farmer, Onion, of which the germinating power is 24 per cent., you do not destroy that seed?—No.

You keep that and mix it with older seed of a superior germinating power?—Yes.

It would not be to the advantage of the farmers to buy from you that seed of 24 per cent., as I imagine, though it is not seed?—No; they like to have the best seed.

It is for the convenience of the farmer to mix it with the older seed, then?—Yes.

And therefore you have a large bulk of the superior seed on hand to mix with the inferior in such a case?—Yes.

And in that way the custom has arisen of selling seed of an average growth instead of one varying from year to year?—Yes.

Dr. Playfair.—Is it not a fact that in almost all kinds of seeds you have in different countries different growths?—Yes.

Supposing that you go to the Continent, it may be different from what you are growing in England, and so on?—Yes.

There may be large variation in any one year in different districts and countries?—Do you allude now, may I ask, to seed generally?

Say Turnip and Clover seed, if you like?—Clover I cannot speak to, Turnip seed we never import; then take Onion seed, that seed will often vary considerably.

You have told us that you cannot tell seed that is mixed with killed seed from seed that is mixed with inferior sample, or that it is difficult to tell it?—I think it is difficult, I would be sorry to swear to it.

Then if this Bill becomes an Act, how are you to prove that the seed of the average which is sold has been brought to that average, either by killed seed or by seed of inferior growth?—I think you would have great difficulty in doing so; if you stopped the killing of seed it would go a long way to get rid of the evil; a man who killed seed might be informed against, but I fear you would not altogether get rid of the evil by this Bill.

How am I to tell inferior imported seed which may be reduced by killed seed, if you cannot detect the killed seed?—I do not see how you are to do it.

Chairman.—Would you take in seed which has been naturally damaged before it leaves the hand of the grower, would you buy such an article?—I would not buy it, but I might be obliged to take it in, because our contracts are, that they shall be delivered a fair average sample for the year, but there is nothing said about the growth, and that man, perhaps, is not in any way responsible for the growth.

I think your business is principally in garden and Turnip seed?—Yes, principally; we also do in Sainfoin. If you will allow me to refer to the subject, that is one of the things which you are reported to have mentioned in your speech, as being adulterated with Burnet; well, you cannot buy Burnet seed so cheap as you can Sainfoin; it is not the seedsman who does the mischief, but the farmer by not pulling the Burnet out when he saves seed.

Mr. Cogan.—You stated that you objected to the provisions of this Bill, and you gave as an example, that if you sold Mustard in which there happened to be some Charlock, you might be liable to a penalty?—I think you might, for adulterating it.

The only penalty imposed under this Bill is for mixing killed and dyed seed with other seed, but not for mixing one kind of seed with another?—Then, perhaps, in my mind I have blended my ideas of the Bill with what was stated in the Chairman's opening speech.

THE INTERNATIONAL HORTICULTURAL EXHIBITION AT HAMBURG.

(*Concluded from page* 206.)

FRUIT TREES AND NURSERY STOCK.

This portion formed a very interesting feature of the Exhibition, to the gardening community at least. Prizes were offered for all sorts of fruit trees, such as are exposed for sale in the different nurseries. This was distinctly a nurseryman's class, so that the competition was confined to just a few of the great fruit-tree nurserymen of France—viz., MM. Jamin et Durand, André Leroy, Louis Leroy, Croux et fils, Martin Muller, Baltet, &c., closely pressed, however, by Herr Jurgens, of Nienstadten, Holstein, the able designer of the Exhibition grounds. It was at the International Horticultural Exhibition in Paris in 1867 that we first saw an exhibition of this sort, and we were well pleased with it. At Hamburg, however, the Show was on a much larger scale, covering nearly an acre of ground, which was formed into convenient-sized beds, and the trees planted therein, with good broad gravel walks between. The trees, however, having only been planted here a week or two, had to be divested of all their leaves, which gave the place quite a wintry appearance. All sorts were exhibited, as common orchard standards, pyramids of all forms, wall fruit trees, palmette espaliers, cordons, &c. Many of these forms of trees were extremely handsome, some very fanciful; nearly all were exceedingly good specimens, with their various parts evenly and regularly proportioned. In the matter of fruit-tree training our continental friends are certainly a long way ahead of us, and from this part of the Exhibition some valuable lessons might have been learned.

We cannot here give a list of all the articles exhibited, or the prizes awarded to each. We may, however, state that Herr Jürgens had a very splendid lot of Pear trees, to which the first prize was awarded, "en pyramide aux ailes"—*i.e.*, of pyramidal shape, with the branches all coming out in regular tiers over each other, so as to give the tree a sort of winged appearance. These were very regular and very pretty. Baltet, frères, horticulteurs, Troyes, came in second with the same style. For the best wall tree, palmette form, MM. Croux et fils were first with a fine example of a Pear; M. Baltet second with a Peach which in our opinion should have been first. For cup-shaped trees M. Baltet carried off the first prize, and for cordons of three different sizes we believe Herr Jurgens was placed first. These trees, however, did not please us much, as, although they were remarkably well grown, we could discern but little trace of fruiting buds upon them; they seemed more inclined for a rambling growth.

For twelve common standard fruit trees three-years-budded, three each of Apple, Pear, Plum, and Cherry, there were no less than eighteen competitors, and the first prize was awarded to a very splendid lot exhibited by C. Million, Nurseryman, Lubeck. MM. Jamin et Durand, André Leroy, Louis Leroy, Croux et fils, Muller, &c., all exhibited a great quantity of their different forms of fruit trees, with samples of the stocks they are worked on, such as they grow for sale, which were all deserving of attention.

VEGETABLES.

Of these there was but a very poor display, so far as quality was concerned. A great number of Potatoes were exhibited; they were, however, as a rule, small, but some were very large, deep-eyed, and of a very coarse appearance—not nearly so dainty as the "praties" of our own country. Cucumbers were shown largely—but how? Not as we ever see them in this country, but big, yellow, almost ripe, and full of seeds. In this condition they are always exposed for sale in the market. How they can be used in such condition, however, we have not the remotest idea, excepting it be for soups—certainly not for salads as we are accustomed to. An immense quantity of Haricots (Kidney Beans) and Celeriac (Turnip-rooted Celery), was also shown, both of which vegetables are grown and used to a very great extent in Germany. A beautiful dish of fresh forced Asparagus was shown, and excellent Cauliflower. Great quantities of Pumpkins, Kohl Rabi, Black-skinned Turnips, and fine Carrots were also present. The majority of the articles here, however, presented anything but an inviting aspect, and contrasted very unfavourably with our own home productions.

ARRANGEMENT OF FLOWERS.—BOUQUETS, &c.

For this section a great number of prizes were offered for all styles of arrangement of Cut Flowers—in the epergne, for the dinner-table; bouquets in vases, for ball-rooms, for weddings; for coiffures, wreaths, garlands, &c. It was expected that this would form a very interesting portion of the Show; with it, however, we were much disappointed, as we had formed very high notions of the skill displayed in flower-

arrangement by our German friends. We shall not, however, be going beyond the bounds of truth when we say that out of the whole collection (some 200) there was not a single good arrangement of flowers shown. The common error of attempting to do too much was here fully displayed. Instead of a few simple colours being used, harmonising well the one with the other, the endeavour in every instance seemed to have been to have variety, the whole being without harmony and without taste. That which pleased us most was truly the most simple—composed entirely of sprigs of green Myrtle, with the pretty white Myrtle flowers intermixed, or studded over the surface. A little wreath, composed of the same materials, was also pretty. In contrast with this modest quiet beauty there was another wreath formed entirely of the flowers of the double red Pelargonium, also a bouquet in a vase of the same, intermixed with a little green Fern, which pleased greatly. These had such an artificial look that it was necessary to inspect them very closely to make sure of their reality. The novelty of the articles used, added to their tasteful arrangement, attracted much attention. A large bouquet of Roses, measuring about 2 feet in diameter, attracted a considerable amount of attention, the flowers being beautifully shaded off in their different colours, from white in the centre to deep red outside, reminding one much of the shading of colour in Berlin wool work. Some of the bouquets and vases of flowers were of an enormous size, from 2 to 3 feet across, and composed of every possible variety of flower.

Here we observed also, for which prizes were awarded, some fronds of Cycas revoluta, having attached a small bouquet of white flowers tied up with white satin ribbon. It is a custom peculiar to some parts of Germany, on funeral occasions, for the mourners to carry fronds or leaves of this plant, and for the coffin, &c., to be similarly arrayed. For this purpose these plants are largely cultivated in Germany, and the sale of their leaves forms one of the most lucrative portions of the trade in some of the nurseries.

MACHINERY AND IMPLEMENTS.

In this important section the Exhibition was not so good as might have been anticipated. Here, however, the English exhibitors greatly predominated over the German, both in the number and quality of their articles. Prizes were offered for the best machine for transplanting large trees, and for this Messrs. Barron & Son, of Borrowash, Derby, Messrs. Peter Smith & Co., of Hamburg, and others competed. The first prize was awarded to Messrs. Smith & Co.; but upon what grounds this judgment could have been arrived at, excepting that in the one case the machine was altogether larger, and happened to be loaded with a bigger tree, we, like everyone else who saw the two machines, entirely failed to make out. We consider this judgment very unjust, and a piece of gross partiality. We all knew in this country with what perfection Messrs. Barron can and have for many years conducted this sort of work, and we confess we think it rather hard for them to be thus beaten by a clumsy lumbering machine like Messrs. Smith's, which is entirely incapable of performing its work. The prizes were awarded without a trial of the machines, so that the Jury had nothing to guide them. If Messrs. Barron's request for a trial had been allowed, the decision must certainly have been reversed. For mowing machines several English firms competed—viz., Messrs. Green, Boulton, Ransomes & Sims, and others, the first prize being awarded to Messrs. Ransomes for, no doubt, a very excellent machine. Williams's new patent Archimedean lawn mower was also shown. This, it may be observed, is of an entirely novel construction, the most simple of all. There is no box for gathering the grass, that being scattered on the lawn. It is, in our opinion, the best lawn mower yet introduced, and the greatest economiser of time in the operation.

Messrs. W. S. Boulton, of Norwich, horticultural engineers rising rapidly into notice, exhibited a large number of garden engines, water-barrows, garden chairs, &c., for which they received the prize given for the largest and best assortment of garden furniture. We can speak in very favourable terms of their garden engines, which are of extremely powerful action, and of simple adjustment. A very ingenious watering-pot engine, or syringe combined, was also exhibited, and for small gardens it might prove extremely useful. Messrs. Boulton's swing water-barrows are also a great improvement, and deserve to be better known. The new hydronettes were also exhibited. We cannot, however, say we admire their action much; the water is thrown forth in too jerky a fashion instead of gently continuous. Messrs. Schmidt & Francke, of Osnabruck and New York, exhibited a great quantity of garden tools—hoes, forks, rakes, axes, hatchets, bill-hooks, &c., of many peculiar forms and patterns. Excepting in the case of some of the hatchets, which were certainly very recommendable, we could see little to take our attention. Messrs. Ch. Delacroix, Ghent, exhibited a peculiar style of heating apparatus, so peculiar that we did not in the least understand it, or how the water was made to circulate; all the three pipes proceeding from the boiler, and continuing exactly on the same level the entire distance, which was the flow or which the return we knew not. All were equally hot throughout a distance of 50 feet. A first prize was awarded. Shading for hothouses was also exhibited largely; the prize was awarded to an article peculiar to the Continent, where the houses require a thicker shade than in this country. This shading is simply thin laths, about an inch in breadth, fastened together by some thick string. This, when painted green, as it usually is, has a very pretty appearance on the roofs of the houses, and may be rolled up as easily as canvas. We wonder it has never been adopted in this country.

Messrs. C. Buhring & Co., Hamburg, and Silver Street, London, exhibited a quantity of their new Charcoal Flower Pot, which they are attempting to introduce. We can as yet say but little about these, only that we know charcoal is a material very much relished by the roots of plants. The pots themselves, which are made of a composition of pitch and charcoal, afterwards burnt, are of very firm substance, yet very porous, absorbing a great quantity of water, which the charcoal sweetens, the material acting as a filter. Slabs are also made of this, which are intended for use as stages, instead of slates, also linings for walls, &c. We are of opinion that some good will come out of this, and that if these charcoal pots, &c., can be produced at a reasonable price, they will prove very serviceable for some classes of plants. They deserve a trial, at all events.

Messrs. Veitch & Sons, Chelsea, exhibited also a great quantity of garden tools, knives, &c., and there were, besides, many other exhibitions in this section which our space forbids us to notice.

MISCELLANEOUS SUBJECTS.

One large building was entirely devoted to subjects of a miscellaneous character—a sort of horticultural museum. Here Senator Goddeffroy, of Holstein, exhibited an extremely interesting selection of articles from his private museum—an immense variety of dried Fungi and Herbaria, &c. Here also Dr. Laudois and Dr. Altun exhibited one of the most interesting collections of Insects, &c., such as are useful or injurious to vegetable life, that has perhaps ever been seen, these being accompanied with specimens of their works or depredations on the various plants. In their various stages of development, they formed a really useful and instructive exhibition. There was also exhibited a very fine collection of all resinous matters, copal and other gums, &c. Immense quantities of fruits, preserved and dried in every conceivable way, were likewise shown.

Messrs. Ernst & Von Spreckelsen, seedsmen, Hamburg, exhibited a very large and excellent assortment of all kinds of grain, garden seeds, &c., arranged in very beautiful order in pretty conical glass bottles. Messrs. Veitch & Sons also showed a fine collection of English garden seeds.

Messrs. J. M. Krannick, Thuringen, F. & A. Haage, Erfurt, and A. H. Hobbel, Hamburg, each exhibited great quantities of flower stakes, labels, trellises, and fruit boxes, all made and arranged so neatly that, simple objects as they were, they did not fail to attract a considerable amount of attention.

Dried flowers, Everlastings as we call them, were also exhibited in endless array by Messrs. Hobbel, Hamburg, Handel, & Co., Hamburg, and others. This is a feature in the floral line which is carried to a great extent in Germany, and enormous quantities of these dried flowers are annually exported. Almost every flower, even the Rose, is dried and preserved in the same manner. We believe it is accomplished by some process of slow baking. The dark colours seem to hold pretty well; the light ones, however, are all dingy, and all the bouquets we have seen made of them have a very flimsy tinselly look, not at all pretty.

A very remarkable lot of bouquet papers and holders was here also shown by M. Vollmer and Gustav Demmler, of Berlin. Everyone who has had any practice in bouquet-making, and the fitting of the papers now in common use, well knows what ill-fitting, inconvenient things they are. Some of the papers exhibited were exceedingly well adapted for their intended purposes, being made of such a shape as exactly to fit the shape of the bouquet without cutting or pinning. Some others of these papers were so elaborately got up—so much fancywork executed upon them, and so bedecked with ribbons, &c., that, as many observed, even with the choicest flowers it would be difficult to tell which were the prettier, the flowers or the paper holders. These, however, were simply overdone, in order to show the maker's skill in ornamentation.

In the gallery of the great plant house were exhibited a number of drawings of horticultural buildings, &c., amongst which there was nothing very striking. Herr W. Hochstetter, University gardener, Tubingen, Wurtemburg, exhibited here a very extensive and excellent collection of dried Conifers—some hundreds of species, all in most excellent condition, and full of interest.

A very splendid lot of drawings of fruits—Apples and Pears—was also exhibited by Dr. Ed. Lucas, Director of the Pomological Institut, Rutlingen. These were well and faithfully executed in colours, and deservedly admired.

We now close our report of this great Show. Many objects in this vast gathering, although of much interest, must have necessarily escaped our notice. It would have been, indeed, impossible to have noticed all. We have, however, we hope, reported faithfully, and if at times we have been severe, we believe we have been just.

In the report of last week read "Blankenose," not "Blankenose;" "Nieustadten," not "Nieustadten;" "Boskoop," not "Borkoop;" "Brockenberg," not "Brockenberg;" "*Aulnay* Lez-Sceaux," not "*Avenay* Liz-Sceaux;" "Villa Monrepos," not "*Mauressas*;" "Bigarreau Monrepos," not "Bigarreau *Maureesses*;" "Marien, Baumanns rother winter," not "Marien Baumanns rother winter."

CRYSTAL PALACE.—A fine spar of Abies Douglasii (135 feet above the ground) has been erected as a flag mast adjoining the Tropical Department on the road front of the Palace; a flag

was hoisted upon it for the first time on Wednesday, the 8th inst., the stars and stripes being appropriately so honoured. The mast was presented to the Company by the late Governor of British Columbia, Frederick Seymour, Esq.

POMOLOGICAL GLEANINGS.

Hathen's Red Gage (Reine Claude Rouge de Hathen).—This is a new Plum, sent us by Mr. Rivers. It is large; in size, form, and colour, it is very like Victoria; but the flavour is like that of a Gage, the flesh separates freely from the stone, and the juice is very rich. This is a great acquisition; the young wood is bright and smooth, while that of Victoria is downy.

—— Yellow Magnum Bonum.—This is another Plum sent by Mr. Rivers. It is perfectly distinct from White Magnum Bonum. It is a medium-sized oval fruit, with a dull yellow skin sprinkled with red dots; it is also a clingstone and with a rich flavour; the young shoots are smooth. All these are characters which bring it very near Jefferson and Coe's Golden Drop.

—— My Lawton and Dorchester Blackberries are ripe (August 20th). They are at least five or six weeks earlier than our English sort, their berries more conical, and not quite so large as we have on our Brambles in good soils. They have the same flat, mawkish flavour. Thousands of bushels are sent to the markets in the northern States of America, where they are very popular. It is curious to note this boyish taste in our transatlantic cousins; they must be very simple and innocent, for here Blackberries are only eaten by very young folks. —Rubus.

—— The Early Favourite Plum.—This nice early Plum was raised many years ago by Mr. Rivers with the Early Prolific, and is often mistaken and sent for it. It is, however, quite distinct, having downy shoots, and fruit smaller and more round. Against a south wall it often ripens early in July. It is so juicy and refreshing, as to remind one of a Black Hamburgh Grape.

—— Messrs. Bunyard & Son, of Maidstone, have sent us again fruit of that delicious little seedling Apple we figured and described last year, in Vol. XV., page 284. It is all flavour, and the flesh is very tender. It is a pity it is so small, but in this respect it will rank among Apples, as the Seckle does among Pears.

—— The Atlas Nut.—We have had a Nut sent us by Mr. Rivers called the Atlas Nut, but why so named we do not know. The nut is short and roundish, and of a good size, a good deal like the true Cob (not the Kentish Cob); but has a long husk projecting beyond the nut. It produces fruit from seven to eight in a cluster, and the kernel is very full and firm. The shell is pale brown.

THE STORM OF SEPTEMBER 11TH.

Last night (11th inst.), or rather this morning, this neighbourhood was visited by a most terrific storm of wind and rain, doing great damage to the Hop plantations and fruit crops in the neighbourhood. Coming as it did from the south-west, and there being a valley from that direction to Lillesden, it had a most damaging effect on these gardens. Bushels of fruit of different kinds are blown down, and some trees; while the green crops, such as late Peas, Scarlet Runners, and Broccoli, are blown in all directions, and the foliage much battered about. In the more ornamental portion of the grounds large limbs are blown off trees, and other damage done. Even some standard Laurustinuses in slate tubs, weighing 2 cwt. each, were blown over; but it is surprising to see how well the Wellingtonia, Pinus insignis, and Taxodium sempervirens stand the wind in an exposed place like this, while the Deodar, Douglas Fir, and Pinus excelsa, appear affected by it, though not so much so as at some places.—T. Record, *Lillesden Gardens, Staplehurst, Kent.*

[We have received similar accounts from Mr. Perkins, Thornham Hall Gardens, Suffolk, and other correspondents.]

"WHO IS TO BLAME?"

The remarks of "C. C. E.," in last week's Journal surprise us, and as we (in conjunction with Messrs. Hurst & Son), introduced Laxton's Supreme Pea to the public, we hasten to reply.

Presuming that your correspondent purchased the true variety in a sealed packet, his experience is astonishing, and as far as our reports go, exceptional. It is a well-known fact, that to publish an actual standard of the height of Peas is impossible, inasmuch as on some soils and under certain influences Peas run quite away from their real character. With this fact in view, we endeavour, when deciding the description of any new Pea we may introduce, to fix the standard as that most likely to be generally acknowledged, and in this instance we were guided by the reports of the Royal Horticultural Society, and our own observations during trial.

We feel sure, therefore, many readers of the Journal will be as much surprised as ourselves at "C. C. E.'s" remarks on this point. Now, as to our statement of the qualities of Laxton's Supreme Pea, it is sustained by several published authorities. In addition, a correspondent in Yorkshire forwards a provincial newspaper announcing a show of Peas, from which we extract the following:—"All the Peas shown were Laxton's Supreme, a new and superior kind. There were twenty dishes shown. The smallest number of Peas in each pod was eight, the largest containing thirteen, the average being ten."

Another correspondent, Mr. Henry May, seedsman, Bedale, says—"I think Laxton's Supreme an improvement on Prolific. It took the first prize at Carthorpe Show, beating Veitch's Perfection and other well-known kinds."

We may also mention, that at the Manchester Meeting of the Royal Horticultural Society, in the collection of vegetables that secured the Cellini cup prize, the Peas shown were Laxton's Supreme and Laxton's Prolific. We are constantly receiving similar evidence, whilst the gratifying reports appearing almost incessantly in the gardening journals are worthy of note. As regards the price of an article, it is worth just what it will fetch, and in practice we may mention, that if we had possessed three times the quantity of the Pea in question, we could have sold it at the same price. From this it appears to us that there is a large section of the gardening world who do not look upon 3*s.* 6*d.* per half pint as a high price for a first-class novelty. In his condemnation of Laxton's Supreme, "C. C. E." pits his judgment against the decisions of the Royal Horticultural Society's trials at Chiswick during two years, and also against the judgment of ourselves and Messrs. Hurst & Son, who were induced to give something like £100 per bushel for stock seed, because we fancied, and are still of opinion, that it is a grand Pea.

If seedsmen are enterprising enough to give these large amounts for really good novelties, "C. C. E." must expect to pay 3*s.* 6*d.* for a sample, or look at the Peas in his neighbour's garden instead of his own. We may add, that we have several other first-class Peas of Mr. Laxton's which we intend offering to the public, and before we introduce them we do not expect them to please everybody, but we are equally certain the majority of the gardening community will thank us for bringing them under the public notice.—James Carter & Co.

A FEW OF THE FERNY COMBES OF NORTH DEVON.

The angle formed by the meeting of the bases of two adjoining hills has various names, and I have seen examples of all such angles—the Valleys of Switzerland, the Glens of Scotland, the Dales of Derbyshire, the Vales of Somersetshire and Wales, the Ghauts of India, and the Passes in many lands, yet none resemble the Combes of Devon. These Combes are many-branched; have breadths of grass so green, have such steep sides, often wooded, always densely clothed with entangled underwood and briars, are threaded by a stream, and are rich in Ferns. Their soil, their climate, their shade, render them specially the home of Ferns—they abound and thrive rarely. And so do legends. There are near the shore of North Devon more than twenty places with names ending in Combe, and I verily believe each Combe has its legendary tale, always a combination of love, murder, catastrophes, skeletons, and ghosts. I have heard a dozen such. There is Crosscombe near Lynton has two legends, for there flits the ghost of the daughter of one with the unpronounceable name of De Wchehalse, who threw herself in despair from Duty Point when the noble lover who had wooed and won her proved false; and there the spirit of Sir Arthur Chichester wanders on the coast as penance for his sins. Then there is Woolacombe, where the ghost of the

De Tracy who aided in murdering Becket is doomed for ever to make wisps of unadhesive sand. Since that murder they say hereabouts

"All the Tracers
Have the wind in their faces."

Shall I mention any more of these wild traditions? Yes, one more, that of Chambercombe. This genuine example of a North Devon Combe is about two miles from Ilfracombe, about one mile from Bicklescombe, and the same distance from Warmscombe! Its steep sides are clothed with Oaks; along its bottom rapidly runs a stream; Ferns, as well as Geranium phæum, and Erodium moschatum, and Aquilegia vulgaris abound; and not far off—at Hele, is found the wild Balm. Long have the Champernownes been connected with this portion of Devon; but the earliest notice of their connection is especially applicable to my notes, for in the eighteenth year of the third Edward's reign, more than five centuries since, "William Champernoun" had wrongfully deprived James de Audeley of the right of presentation to the church of "Ilfridcombe," as it was then spelt. Champernonscombe, as it was once called from belonging to that family, was estreated to the crown; yet a member of the family continued its tenant, and by his ability as a farmer accumulated money. His only child, a daughter, was united to a wealthy foreigner, and her father after the lapse of some years began to see a prospect of repurchasing the forfeited estate. At this juncture, during the night, when one of those fearful storms which visit our western coasts was raging, a vessel bound for Bristol was driven on the rocks nearest to Champernonscombe. The tenant saved a lady from the wreck, and carried her home. About her person and fastened round her waist were jewels of great value and a large sum of money. To all inquirers he said he knew of no survivor of the wreck. He appropriated her property to his own use, and was thus enabled to complete the purchase of the estate. The lady had not survived the injuries she had received; and to conceal the body he boarded up the window, and built up with cob the doorway of the small room in which her body was lying. Ere long information reached him, showing that it was his own widowed daughter who had thus perished on her voyage back to her old home. Her father could now no longer endure to dwell on the estate he had so long coveted and by intended fraud had purchased. He let the whole, stipulating that no one should reside in the house, and this vacancy he provided should be continued for several generations. At length it passed into other hands; and it being observed that there were five windows but only four chambers, an opening was broken into the closed room. In it were a bed draped and a lady's dresses, all of the style prevalent during the days of the last of the Stuarts, and in the bed was the skeleton of a woman. The confessional narrative was found among the papers of her father. The house, of which I send you a sketch, is at the end of a Combe which I visited oftener than others in search of Ferns.

North Devon is truly "The Land of Ferns," and deserves this title, not only because of their there abounding, but because you continually fall in with something or some one demonstrating their prevalence and their culture. By the side of every country path you observe fragments of fronds, telling that collectors have passed that way. In the front of cottage doors, far away from a town, you see boards bearing inscriptions such as this—"Ferns sold here by John Lewis." In the towns there are professed Fern-growers and Fern-propagators. There are two such in Ilfracombe, named Moule and Dadds. They have followed the employment for years, and have fernerias—terraces cut on the shady side of a rock, in which they grow not only the species but many of their chief varieties. They have small greenhouses, and there in pans I saw thousands of seedlings raised for sale and to test whether the varieties are permanent. I have always upheld local naturalists' clubs, because I know from personal experience the protecting influence of those associations. The man who has such a mental employment and congenial companions for his leisure hours, has a sound and evergreen fence against evil. Such a club is that of Todmorden in Lancashire, and no better evidence of its good influence need be quoted than that its secretary and some of its members had travelled into North Devon, and enlisted Mr. Dadds as their guide in search of Ferns. The very donkey-drivers are learned in Ferns, and I especially recommend one of them, Mrs. Rowe, to those of your readers who are lovers of Ferns and who visit Ilfracombe. She knows where the species are to be found, and I tried in vain to puzzle her by showing her mutilated fronds. The Maidenhair, she says, is obtained now not only from White Pebble Bay, but from a bay just beyond Helesborough and from Lundy Island. The history of this worthy Fern-and-donkey woman is not without interest, and points a moral. She was a lady's servant, took to herself a husband, and when the loss of an arm disabled him from pursuing his usual occupation, they, nowise daunted, became the owners of donkeys and donkey-chairs, and guides to the Fern-seekers.

Here, too, resides the authoress of that pleasant little book "Ferny Combes." None but a lover of the wild and the beautiful could have written its eight introductory chapters. She is the wife of the Rev. Mr. Chanter, rector of Ilfracombe, and there is a biography in this dedication of her volume—"To the Reverend Charles Kingsley and Mrs. Kingsley, this little book is affectionately dedicated by their daughter, as a small token of the gratitude due to them for awakening and fostering in their children a love of nature and beauty." May she and her husband attain the age and be as adhesive as his ancestor, whose memorial in the churchyard records that he lived for ninety-three years, during seventy of which he was perpetual curate of Hartland.

Every one who is not blind must have noticed here and elsewhere how the love of plants and their culture clings to man, woman, and child; even when living in an attic in the closest alley of a town they will have a "Geranium" or a Fuchsia in a pickle-jar or a dilapidated teapot. I once saw a permanent garden on a canal barge. Schoolboys have their gardens, and even old college professors, like Dr. Jowitt, will have a

plot, and stir it with a trowel, even after being lampooned thus:—

"Professor Jowitt a little garden made,
And round it put a little pallisade.
A little garden taketh little wit to show it,
And little wit had little Dr. Jowitt."

This, and much more to the same purpose, came to my remembrance when looking from my window at Ilfracombe I saw a miniature garden, which a table-cloth would cover, having a narrow walk all round, a narrower border crammed with pigmy plants next the enclosing walls, and a grass plot in the centre, so small that its owner was mowing it—clipping it I should say, with a pair of scissors.

Of extensive gardens I saw but few in North Devon, and in them the horticulture was not of superlative excellence. The culture of culinary vegetables is there more successfully pursued than that of ornamental plants, and I was especially interested by the prevalent mode of taking up the Potato crop. The soil is light, and usually are the ridges of Potatoes on a steep slope. The only implement used is a long-bladed hoe, and beginning at the lowest end of each ridge, this long blade is struck into it beneath each Potato plant, and a pull towards the operator brings all the tubers rolling to his feet. The soil and climate are favourable to the growth of the Potato, and upon my so observing to a gentleman whom I casually met during one of my rambles, he replied, "So my ancestor thought, when he, the first field-cultivator of it, planted them near Exeter, exactly one hundred years since." Who my informant was I know not; but Mr. Roberts, in his "Social History," says "One Moore, an Irishman, planted the first field of Potatoes in Devon, at Poltimore, where he resided." Poltimore is about five miles from Exeter.

Although there is no very superior flower gardening in North Devon, yet a love of flowering plants prevails there among all classes, as it does elsewhere in England; and if a Rose tree, Fuchsia, or Myrtle is planted and left to itself, and unprotected, the climate is so genial, that it attains a size and vigour never witnessed in our colder localities. This was further impressed upon me by seeing near Lee Bay a hedge of Veronica Andersonii. It is a common error to connect the name of *North* Devon with the conclusion that its climate must be more severe than that of *South* Devon. So far is this from being the truth, that the mean temperature of Ilfracombe, Lynmouth, and their coast vicinities is slightly higher than that of Torquay, with this additional advantage, that the average summer temperature is lower, and the average winter temperature is higher—a fact explicable by our knowledge of the Gulf stream flowing along its shore.

In no other year have I noted such a frequent occurrence of white variegation in the foliage of our native hedge-row plants. Such abnormal colouring is rarely permanent; but this is not the case, we know, with our garden plants, cultivated for this peculiarity. I was introduced, at Chippenham, to a gentleman who admires especially white-variegated-leaved plants, and he showed me a Wych Elm in his garden that has the natural green foliage on its topmost and lowest boughs, whilst those on the central branches are white. This gentleman, Charles Bailey, Esq., is one of those who indulge largely in "the luxury of doing good." Not only has he built residences and endowed them for decayed practitioners of medicine and their widows, but is generally the friend of the distressed. His scientific collections show that his head as well as heart "turns to what 's most wholesome," and his garden evinces that admiration of things graceful is not incompatible with a love of things of thought, and things of kindliness.

I must now lay down my pen, for I had only a Parthian glance at that most Swiss-like district of North Devon about Lynton. If Moore had seen the "Waters' Meet" near Lynmouth, he would not have written, unless as specially applicable to it—

"There is not in the wide world a valley so sweet
As the vale in whose bosom the bright waters meet."

If the poet had looked upon the North Devon "Waters' Meet," he would have seen that the Combe, in which join the streams of the Lyn and the Brend, is quite as "sweet" as that valley in Ireland where those of the Avon and Avoca unite.—G.

DEATH OF MR. VEITCH.

It is again our painful duty to record the death of another eminent horticulturist—one whose name has been often on the lips, and prominently in the minds, of all lovers of plants wherever civilisation has spread. On Friday last, the 10th inst., died at Stanley House, King's Road, Chelsea, Mr. James Veitch, the head of the firm of James Veitch & Sons, aged 54.

Mr. Veitch was the third in succession of three generations of nurserymen of his name, who for nearly a century have occupied a prominent position in that branch of industry. His grandfather, a native of Jedburgh, in Scotland, established a nursery at Killerton, near Exeter, towards the end of the last century, and there the subject of this notice and his father were born; the former on the 24th of May, 1815, and the latter in 1792.

Early in life Mr. Veitch exhibited those tastes and qualities of mind which developed with his years, and combined to make him in after-life the man he was. When yet young his father sent him to London to gain the experience which at that time could only be obtained in a London nursery. The provincial establishments were in those days much more dependant on the London nurseries for novelties and supplies than they are now; and it was to London—severed though it was at that time from the rest of the country by long roads, and reached only by stage coaches and stage waggons—that all who wanted improvement and extended experience and knowledge, were usually attracted. Mr. Veitch, always ardent in the love of his pursuit, was first sent to the nursery of Chandler & Son, of Vauxhall, at that time the special attraction for the culture of the Camellia, and then for a short time to that of Mr. Rollisson, of Tooting, in whose family he resided. We mention this fact because it has a bearing on Mr. Veitch's future, and on that of the Exeter and Chelsea nurseries. As his son was at Mr. Rollisson's for improvement, and at the same time living in his family, Mr. Veitch, senior, prudently thought that some compensation was due for the favours his son was receiving, but the Messrs. Rollisson firmly declined to entertain any such proposition; and Mr. Veitch commissioned the subject of this memoir, before leaving Messrs. Rollisson, to purchase from them plants to a certain amount, as a graceful acknowledgement of the favours and advantages he had received in their establishment. Orchids were at that time just coming into vogue, and our young nurseryman exercised his taste and his judgment in making a selection of Orchids, among which were Oncidium papilio and other rarities of that period, with which he started on his way homewards; and these were the beginnings of those Orchid collections which have now for many years made the nurseries of the Veitches famous.

About this time the long-contemplated removal of the nursery from Killerton was being carried out; and whether it was in consequence of the new ideas and fresh impulse he had acquired by his experiences in London, or the natural development of an establishment which had still within it the united judgment of sire and grandsire, true it is that from the time of Mr. James Veitch's return to Devonshire the Exeter establishment took a development which progressed with wonderful rapidity, and never ceased till it became without exception the most important and noted of the provincial nurseries. The Orchid purchase, and we suspect also the fresh knowledge which only stimulated a taste already strong, had their effects in giving a direction to the nature of the business which was in future to be the distinguishing characteristic of Mr. Veitch's life. It was not long before a search for Orchids and new plants was to be made in their native habitats rather than in the London nurseries, and accordingly in the year 1840 Mr. William Lobb was despatched to Brazil to enrich the Exeter Nurseries, and through them the plant collections of England. A house was erected specially in which to raise the seeds sent home by Mr. Lobb; and among the first of his introductions were Dipladenia splendens, Hindsia violacea, Gloxinia speciosa var. macrophylla variegata, Begonia coccinea, Manettia bicolor, Echites atropurpurea and hirsuta. Hypocyrta strigillosa, Stigmaphyllon ciliatum and heterophyllum, Tropæolum azureum, Rondeletia longiflora, Gesnera polyantha, and many others.

Encouraged by the success that attended Mr. William Lobb's mission, about three years after his departure for Brazil his brother, Mr. Thomas Lobb, was sent to Java, and there began the foundation of the Orchid collections, which culminated in what may be now seen in the exhibitions of Messrs. Veitch and Sons at the great shows and in their immense collection at Chelsea. Those who knew Mr. Veitch well could imagine the delight with which he would hail among the first receipts from Java such plants as Phalænopsis grandiflora and Vanda suavis, for they were of the earliest that arrived. To follow out in detail all that was done by the Messrs. Veitch of Exeter would occupy more space than we have at command. The time came

when the subject of our notice was constrained to remove from the parent establishment. An opportunity offered which, with his keen perception, he saw opened a field for his energy and enterprise, which the narrow limits of a country nursery did not afford, and accordingly in April, 1853, he left Exeter and came to London.

For a long series of years the Exotic Nursery of Joseph Knight, of Chelsea, carried the sway as the centre of attraction for new and rare plants; but at the period about which we are now writing it had fallen much into decay, and required new life and energy to resuscitate it. There was none better qualified for such a task than Mr. Veitch, who in April, 1853, became the purchaser and sole proprietor, though the designation of the firm was "Veitch & Son, of Chelsea and Exeter;" the same accord continuing between the two establishments, although in reality separate and distinct. The history of this establishment has been the history of English horticulture for the last sixteen years. The collectors who were sent out and the plants which were sent home all added fresh lustre to a nursery which had at its head more fire and energy, coupled with keen perception and sound judgment, than perhaps fell to the lot of any other in the kingdom. Among these collectors let us not forget to mention his own son Mr. John Gould Veitch, who in his one journey to Japan and the East, and his other to Australia and the South Pacific Archipelago, added numerous treasures to the botanical and horticultural wealth of this country.

In sixteen years, through the exertions of this one man, and yet ably seconded by two sons, whose devotion has been only second to that of their father, the Exotic Nursery at Chelsea, with its extensive adjuncts of Coombe Wood and Fulham, has risen to be the largest and most prosperous in England. May we not say in Europe?

And now his labours are ended, the work he had to do has been accomplished, and he has retired to his rest, leaving behind him those who are fully qualified by their knowledge and experience, and devotedness to their pursuit, to maintain the position and reputation their father has built up.

The disease from which Mr. Veitch suffered was an affection of the heart. For nearly twelve months he has not taken an active part in business, the whole management having devolved on his sons. Yet there were no symptoms which gave rise to any immediate apprehension of danger. Three days before his death he deliberately walked up to Brompton Cemetery, which is close by, and without the knowledge of any of his family selected the spot for a family grave. He could not be assured as to the depth which he required being attained, and left the completion of the purchase till that could be decided; but with all his business habits to the last, he stood by till the attendant with a spade marked out the space, so that, as he expressed it, "If anybody should want it, it belongs to me." The day previous to his death he received a visit from his old collector, Mr. Thomas Lobb, and whether the excitement consequent on the pleasure he derived from seeing his old friend, or that nature itself was exhausted, is not known, but on the following morning at a little after three o'clock, he felt an oppression in breathing, and with all his faculties about him, and surrounded by the members of his family, he breathed his last.

We understand that the business of the Royal Exotic Nursery will be continued as usual in its integrity. No change will take place either in the organisation or in the working, but all will be conducted as it has hitherto been with that care and energy which have already secured for it so high a position.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The weather being favourable, proceed with work which can be most advantageously done when the soil is in good condition. It is advisable to adopt precautions at this moment, to avert the effects of early frosts from the last crops of *Kidney Beans* and other tender vegetables. If *Globe Artichokes* are desired at an early period of the year, some strong suckers should now be selected and potted; if protected by being placed in a cold pit throughout the winter, and planted out early in the spring, they will bear at least a fortnight sooner than the old plants. Prick out an adequate supply of young *Cabbage* plants. A good store of *Lettuces* should be planted in a position where they can be protected from heavy rains. The general crop of *Onions* will be fit for housing by this time; see that no decayed bulbs are stored with the rest. The ground they have occupied should be dug on their removal. Cabbages would be a good successional crop. Lights from the Melon pits, sloped against the wall, will both protect the *Tomatoes* and hasten the progress of their fruit. Thin young crops of *Spinach*, *Turnips*, &c., before they become weakly and drawn through standing too closely together. Stir the surface of the soil deeply among growing crops, to admit air to the roots and keep down weeds. Manure spare ground, and dig or trench it for another crop whenever time can be spared.

FRUIT GARDEN.

Remove rubbish of all descriptions from fruit-tree borders. No obstacles should prevent the roots having the full advantage of favourable weather. Gather carefully the various Pears and Apples as they arrive at their full growth. Discard at once bruised fruit, it entails ultimate trouble.

FLOWER GARDEN.

Should the Verbenas or other mass flowers show signs of exhaustion, manure water will be found a useful stimulant; it is advisable to induce a vigorous growth in Verbenas at this period, and so manage to repress the mildew. See that faded blossoms and seeds are regularly removed from beds, other blossoms will be thus encouraged; much of the vital energy of a plant is expended in the perfection of its seeds. As soon as the beds can be spared they should be prepared for the reception of bulbs. Where many cut flowers are required, it is of great advantage to possess a flower border near any large building, for the heat thrown off by the latter at night is sufficient to prevent injury from early frosts, or a little covering at night secures their safety. In other cases certain beds should be selected and regularly matted at night. Use the present opportunity of effecting a complete clearance of weeds from walks and borders. As has been often recommended, give careful attention to young stock, and recollect that sturdy, well-rooted plants are much easier to winter than large plants with long-jointed soft wood. With good convenience, late-rooted cuttings may still be potted-off, but unless they are very close together in the cutting-pots, it is better to winter them in these rather than shift at this season, for they occupy much less space in the cutting-pots, and having more room for their roots, they are frequently more healthy, and require less attention in winter than those which are potted singly. Square pans, 12 inches wide and 5 inches deep, are very suitable for wintering cuttings of Verbenas, Lobelias, and other plants which can be kept in a small state. One of these will hold twenty good plants, and with care, to prevent their being injured by damp, they may be wintered quite as well treated in this manner, as if potted singly in 4-inch pots, and a vast number may be stored in a small space. Where cuttings of such plants have to be kept in cold frames or pits, the plants should be potted singly, as they would be very liable to damp-off, notwithstanding every care, if placed thickly together in pans, and put where it may be impossible to give air for weeks together. The practice of wintering bedding stock in unsuitable places, is generally adopted from some mistaken notion of economy; but if a fair calculation of the time required to attend to plants wintered in this way could be made, and all the losses taken into account, it would be found to greatly overbalance the trifling cost of putting up a proper heating apparatus, and consuming a few bushels of coke or coal annually.

GREENHOUSE AND CONSERVATORY.

In the management of the majority of plants in these structures, it is very desirable to produce a robust hardy growth, and afterwards to lessen the activity of vegetation, that they may gradually accommodate themselves to the changing circumstances of the season. Ventilation judiciously managed will assist in accomplishing the desired result, and water will be required in less quantities both for the roots and foliage. Be prepared with specimen plants in flower to supply the place of those going out of bloom. If early Camellias are wanted, let some of the most forward be placed in a rather close house to induce them to open their buds, giving them a regular supply of manure water. Some of the earliest Epacrises may be placed in a close part of the greenhouse, where they will soon open their blossoms; also Daphnes and many other plants, provided their flowering buds are prominent. Aim at keeping the atmosphere of the house rather dry, using just enough fire heat in damp cold nights to allow of giving sufficient air to keep the atmosphere in motion, so as to prevent damp from being injurious. Shake out and repot Pelargoniums which are sufficiently advanced after having been cut back, keeping them rather close and moist until they strike into the fresh soil. Plants, how-

ever, that are fairly established after repotting can hardly be too freely exposed to the air, or kept too cool. Let Cinerarias also be kept cool and moist, and attend to repotting such as may require it. Primulas must likewise be carefully attended to in order to encourage them to make rapid growth, particularly the double varieties. Summer-flowering twiners, which usually become unsightly about this season, should be cut back rather freely, likewise any others that will bear this treatment. Shade can now well be dispensed with; therefore, not a spray that can be spared should be left to obstruct the light.

PITS AND FRAMES.

Continue to pot-off cuttings from the first batch of bedding plants. It is important to have Scarlet Pelargoniums established and hardened before winter. Pot Neapolitan Violets, and let them be plunged in a frame. Lily of the Valley for forcing should now be potted, and Mignonette placed on an exposed and warm shelf in the greenhouse. A week or two after the cuttings are struck, let them have a few weeks out of doors if possible. This will revive them much before winter, and will also enable them to bear confinement better. —W. Keane.

DOINGS OF THE LAST WEEK.

What a pity that fine bright weather should ever do harm! For a month or six weeks, we question if the flower beds ever looked more full of bright blossoms, and the foliage, though not massive, was of a healthy green. By the 7th one of our chief reservoirs of water was exhausted, and watering flower beds became quite out of the question. On the afternoon of the 9th the plants in some beds began to flag, though they had been mulched to keep moisture in. We had lightning all night on the 9th, and thunder and rain on the 10th, and though the rain has been a blessing to fields, pastures, gardens, and even eventually to flower gardens, it has in the meantime, in connection with the strong winds in the afternoon, shorn the beds for a time of their beauty. Blooms that would have stood the dryness a few days longer, fell or became blotched under the force of the rain and winds. Some excellent masses of the old Brilliant Pelargonium looked on Saturday morning like so many half-drowned mice. Fortunately we had picked a number of beds, removing the decayed flowers, and these picked beds stood the rains well. If it can be accomplished, it is better to remove such flowers before than after rain, as many faded blooms disfigure and discolour what would be sound blooms. The refreshing showers, the most effective we have had since May, will give us a fine appearance again in a few days, and, if we have a fine open autumn, will render us independent of much rain for some time. The frost hurt us a little, still nothing to speak about, but the drought, notwithstanding all our care, was beginning to tell upon us, and all the more as we were husbanding the little water left. We went over a bed lately to gather a handful of Heliotrope flowers, as these were dropping and withering from the dryness, but now they are coming plump again. The lawn, just showing a little sign of distress, is now assuming its bright green mantle, which helps to make everything look so much better. For some time we have allowed the machines to do no more than just nip the outjutting points, as it is bad policy to cut close in such dry weather. The effects of the rain on the kitchen garden have been such that we shall not need the water barrel, except for fresh-planted crops. Turnips will be greatly benefited.

KITCHEN GARDEN.

Cleared off a part of our crop of *Onions*, placing the bulbs under cover until we find time to string them. Put a little dung on the surface, and trenched it down fully 18 inches, thinking the ground rich enough to bear a heavy crop of Cabbages. In this ground planted our earliest plants intended for the spring, in rows, making a furrow for the plants, so as to hold water. Our Onions, though there is a heavy crop, are not individually very large, and in trenching up the ground our only surprise was, that the bulbs were so fine as they are, as, for the depth specified, the soil seemed to be next to dust-dry; so dry that, though it is rather stiff, it would scarcely lie on the spade to be turned over. Roots of Onions were found, however, deeper than our trenching. There seemed to be a good quantity of sweet decayed dung in the ground, and we preferred giving no more, as too much at this time, if at all rank, is apt to make the plants over-luxuriant in winter, and, therefore, more liable to be injured by severe frosts, and if the weather is very mild, makes them liable to bolt instead of heart in the spring.

Almost every one has his pet vegetable, but commend us to a crisp *Cabbage* in spring, just hearted enough to begin to blanch its heart leaves a little without being hard. To obtain a nice Cabbage early, and yet prevent running to flower, is a matter demanding some consideration, and one means of securing it is to avoid heavily manuring with rank dung at this season. If an Onion quarter was well treated in spring, the dung given now should chiefly go to the bottom of the trench. As rotation, we like Onions to follow Celery, and Cabbage to follow Onions. Without extra preparations, Onions after Cabbages are one of the worst of rotations; under ordinary treatment we should expect to see all the ills to which Onions are liable.

Sowed the last Cauliflowers and Lettuces; we merely scratched the surface of the ground for the latter, and covered with fine soil. These are intended to be thinned, and to stand and perfect themselves in spring. When thinned, it is easy to give a little help from manure then, if deemed necessary. They will withstand the winter all the better if the soil beneath them is comparatively hard and poor. Firm, not luxuriant, growth is desirable. Cauliflower will often succeed well if sown at the foot of a wall, and treated in the same way. In fact, we have often known the plants withstand a severe winter, when those protected by frames and hand-lights had given way. Sowed Radishes, thinned and hoed Spinach, &c.

FRUIT GARDEN.

We shall not be greatly troubled with late fruit on walls this season. Even Plums will soon be over, and we gather them when about ripe, or rather before it, to keep flies and wasps from them. The most forward Apples and Pears are being gathered for use, and such kinds as Williams's Bon Chrétien are gathered at intervals, and forwarded in rotation in a warm place, so as to prolong the season.

ORNAMENTAL DEPARTMENT.

The rains, as already stated, have tarnished for a time the brightness of the flower beds, but less so than might be expected. The dryness of the beds so far increased the evil, as then the flowers and their petals are more easily shaken off. We have often proved that when plants are artificially watered at the roots previously, rains, though heavy, do less injury to the blooms. In our case we saw clearly, that without rain or watering, some of our best beds would not have stood many more days of such scorching weather. There are some plants that no rains will ever hurt, as Heliotropes and Ageratums. Calceolarias are only deprived of the blooms that would soon fall naturally, whilst the very thing is given that will ensure a continuance. Scarlet Pelargoniums with many massive heads of bloom fully ripe, suffer most. The Nosegay section suffer least, and in proportion to the smallness of the petals, as the wind and the rains pass between them. The other kinds suffer in proportion to the size of the truss and of the flowers individually. Here, this season, we observe a difference among the large-petaled kinds, as the scarlets, like Punch, Boule de Feu, Defiance, the old kind of Excellence, &c., have suffered more than the rose-coloured ones, as Trentham Rose, Rubens, Admiral Porteous, &c. Such light scarlets as Donald Beaton have also stood better than the dark scarlets. Donald Beaton is very good as a late bloomer. It does not mass so early as some of the others. The deep pink kinds seem also to stand better than the dark scarlets. In Verbenas the same rule holds good —the largest-petaled flowers feel the effects of rainy weather most. No rains we have seen would affect the trailing Verbena pulchella, except to make it brighter. We have a line of Improved Ariosto that was splendid in the dry weather, but to-day is looking washed and dull, whilst a broad line of Purple King, owing to the comparative smallness of the trusses and flowers, is looking all the brighter. Both wanted moisture at the roots, and both will be fine when we have bright sunny weather. Under ordinary circumstances we may calculate on a fine show for five weeks. We notice that some foreboders of evil are already counselling taking up the best bedding plants. If such work must be done in the beginning of September, then the doom of the grouping system with tender plants must be nearly consummated. With favourable weather we expect increased brilliancy in a few days—but this will mainly depend on sunshine—and that with but little trouble further than picking off some decayed blooms, and removing some of the larger leaves, that there may be a due proportion between flowers and foliage. In the dry weather this was scarcely the case, as some beds, as of Christine pink Pelargonium, were so densely covered with bloom that there was not enough seen of the pretty green

foliage. A due proportion between green and bright colouring is essential to a pleasing effect.—R. F.

COVENT GARDEN MARKET.—September 15.

Heavy arrivals again this week, in addition to large quantities of fruit stripped off the trees by the late gales, have caused a temporary reduction in prices. Cob nuts are plentiful; Filberts not more than enough for the demand.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Son, Wellington Road, St. John's Wood, London, N.W.—*Autumn Catalogue of Bulbs and Flower Roots, Roses, Fruit Trees, &c.*

Barr & Sugden, King Street, Covent Garden, London, W.C. —*Autumnal Descriptive Catalogue of Bulbs and Plants.*

Thomas Bunyard & Sons, Maidstone.—*Select List of Dutch Flower Roots.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Tomatoes (*I. G.*).—We do not know what you mean by the Tomato "Groseille à grappes." If the fruit is small and black like a Black Currant, it is unsafe; but if it is yellow or red, and the size of a good large Gooseberry it is perfectly wholesome and may be used as the ordinary kinds. (*Dulcibella*).—The same reply will answer your question respecting your "Grape Tomatoes."

Roots in Water Pipes (*C. C.*).—The roots, probably, of some tree, or trees, have entered the earthenware pipes through their joints. We object to lead in any form for the pipes or cisterns to supply water for use, either by human or animal species. We prefer iron, but if the joints of the earthenware pipes were well cemented no roots could enter. Sweet Peas would not be injurious to fowls if they would eat them. Pigeons probably would.

Swiss Lakes (*Philokepos*).—We cannot admit any discussion on the subject.

Fungus on Pear-tree Leaves (*A Subscriber, Devon*).—The large rusty-brown patches with rough papillated surface, are Roestelia cancellata, a parasitical fungus. They are said to be removable by dusting the leaves with flowers of sulphur, and if this is repeated in any year they reappear, they may be entirely prevented. The "Cottage Gardeners' Dictionary" probably would suit you; but you do not state whether information on any particular department of gardening is wished for.

Plants for an Island (*Dorsetshire*).—For the peaty island we advise planting either the Weeping Birch (Betula alba pendula), and not one but a group of not less than three, or the Cut-leaved Alder (Alnus incisa), which would, perhaps, thrive better if the peat be of a boggy nature. Along with these we would plant the Royal Fern (Osmunda regalis), and nothing else. You might, if you wished, have a few plants of common Dogweed (Cornus sanguinea), and its silver and gold variegated-leaved varieties, one of each. The Weeping Willow is fine for such situations, but the soil is more suitable for the Alder and Birch.

Laurels Dying Back (*H. D.*).—When Laurels become old they, like every other tree or shrub, are subject to decay, and though they may start from the bottom the growths are not of very long continuance, but are continually dying-off, more or less. The branches become dried up, and the leaves assume a bright yellow hue, and though fresh shoots may come from the root, the Laurel's term of beauty is gone. It may exist as a pollard shrub for some years, often many, but will never again make a prolonged healthy growth. There are exceptions, however, in those that push suckers from the roots or stem beneath the soil; they form new roots, have a stem of their own, and in the course of a few years become independent of the old stem and root, which in most instances perishes, and will often be found quite decayed amongst the suckers which have attained the size of the old plant and become a large bush. That bush will, after it attains its full size, be liable to the same decay from age as the old plant, and though it in its turn will put out suckers from the root stem, they will not continue healthy. We do not know the cause of the branches dying after being cut back to a healthy shoot, nor of the leaves becoming suddenly yellow. In cutting down old stems it should be done to near the ground, so as to encourage suckers from beneath the soil, so that they may not derive their food through the old stem, or only temporarily, but have a stem and root free of the old stem and root. Digging round, and manuring with old rotten manure mixed with fresh soil, would be beneficial, a portion of the old soil being removed. It is best to cut them, when much pruning is required, in spring before they begin to grow, and at that time only, irregular growths being removed in August. Dead wood may be cut out at any time except when frozen, and never into the live wood.

Exhibiting Fuchsias (*A. J. J.*).—If a prize be offered for six Fuchsias, it is always understood that Fuchsias with all shades of coloured corollas are included, and unless the prize were offered for six dark corollas as distinct from six white-corolla flowers, the white would decidedly be admissible among six varieties of all shades of colour.

Vine Trained Downwards (*J. R. P.*).—Your Vine will do very well trained down the roof, as you propose; but it would be well to daub the slate roof with a paint made of strong soap water, and soot and sulphur, as soon as the Vines break. This will act as a preservative against the attacks of red spider. The Vine shoots will be shorter-jointed from being trained downwards, after the main stem reaches the top of the wall. Hays's constant stove you allude to is not to be had. We have little faith in any stove without an outlet into the open air; but with prepared fuel, and a stove on the principle of Hays's, we should be satisfied with a small outlet pipe, more for gases than mere smoke. But why, if so good, has some one else not made similar stoves, as the original makers seem to have given them up? Chiefly, because there is the endless trouble about the prepared fuel. We would have a Joyce's stove as soon as any if there were a pipe from it. A good iron stove will suit your purpose, and if you use clean coke a small smoke pipe will do. This you can move when not wanted.

Fruits for South Lancashire (*J. Whever*).—*Apples:* Irish Peach, Kerry Pippin, Cellini, Golden Winter Pearmain, Adams's Pearmain, Cox's Orange Pippin. *Pears:* Peach, Beurré Superfin, Doyenné Bonssech, Doyenné du Comice, Fondante de Malines, Forelle. *Plums:* July Green Gage, Peach, Denniston's Superb, Green Gage, Purple Gage, Coe's Golden Drop. These will do very well for growing in large pots or tubs. The Apples should be grafted on any of the stocks known by the name of Paradise stocks, and the Pears on the Quince stock. The Plums you cannot get on any other than the Plum stock usually employed in nurseries. Louise Bonne of Jersey, Citron des Carmes Pears, and Denyer's Victoria Plum will do well with you.

Planting a Flower Bed (*Y.*).—We must adhere to our rule, and only criticise proposed planting, and not plant. Keeping in view what you say you have, the following would be beautiful and telling:—No. 1, Wallflowers; 2, blue Pansy; 3, yellow Pansy; 4, purple Pansy; 5, white Daisies; 6, Vandyke bands, red Daisies; 7, blue Forget-me-not, edging all round white-variegated Arabis; or 7 and edging might be Arabis, but not be so telling.

Plants Damping-off (*Kettering*).—Do away with all plunging material on your platform, and give air as the weather permits. Mask seed sown now will not bloom much early in the spring. Try to obtain a few roots, and pot them. There is no difficulty in raising from seed, but you must keep the soil moist, and cover the seeds very lightly.

Mulberry Tree without Stamens (*H. G. Merriman*).—We have no doubt that your fruit-bearing Mulberry was fertilised from the other tree at a little distance.

One Boiler for Several Houses (*S. H.*).—There will be no difficulty in heating the different houses from one boiler if the position of the ground is suitable, and is either on a level, or rises rather than falls from the position of the boiler. As you must sink the pipes in crossing the open gravel in a tunnel, the easy working of the pipes in all the houses will much depend on having the top of the boiler sufficiently low to be a feet or more beneath the level of the pipes in the tunnel, and in having the main flow and return pipes rising gently from the boiler to the conservatory, instead of dipping at all. There will be no difficulty in this if the ground is nearly level, or rises from the position of the boiler to the position of the conservatory; but if the ground should fall, you would require a deep stokehole. Independently of the expense of a second chimney, we would decidedly prefer having only one boiler at D, and encase the pipes in a tube or tunnel stuffed with sawdust, where they cross beneath the gravel. You can heat each house, beginning at B, separately, by having a flow and return there to act independently, but with liberty to go on to A when you like, that also to have the circulation complete, and then go on to C when wanted. By this means you must have the flow and return through B before it reaches A, and through both before it reaches C, but you need not have more than the two pipes, and these may be 3 inches in diameter if deemed desirable. If would simplify matters, as you require a great heat in B, and a strong heat in A, to take the flow and return at once to A without any valves, &c., and then

stop the circulation to c, unless when wanted. We thus make these two pipes the mains or feeders, and from them we take what we deem necessary for each house. For instance, your Cucumber house may have conveniences for dung in the chamber beneath, as you propose; but, having the hot water, we would dispense with dung, and have two 4-inch pipes beneath each of the two pits, and two pipes above the soil on each side for the top heat that would be required for early Cucumbers. To have plenty of heat in A, you will need three rows of pipes —two flows and one return. Two pipes would do for the conservatory, but three would be better, as in severe weather the two would do little more than keep out frost, and it is advisable never to have the pipes too hot. The outside border of 4 feet will do for the Vines, but we would widen it inside to 5 or 6 feet, and plant inside. You may easily place good soil under your gravel paths.

Brick Arnott's Stove for a Greenhouse (*W. P.*).—We have not a doubt that the brick Arnott's stove will answer admirably. The 3-inch pipe will do for a chimney if the best coke be used, and the pipe be frequently cleaned. For a pipe of this size we use a rod nearly the diameter of the inside, and that cleans better than any kind of brush. All such stoves should have only a short horizontal pipe, not more than from 18 to 24 inches long. Your proposed oblique pipe, if the incline were sharp, would answer; but it would be more complicated than a short horizontal and then an upright pipe at once. You would need more cleaning, and have more trouble with joints. Of course you could have your pipe moveable at the elbow; but for the little additional expense it would be better to have no elbow at all, but take your short horizontal pipe into a box, say of 6 or 8 inches square, and the same in depth. From the top of the box take your upright pipe, have a door in the box on one side, and you can do all the cleaning without moving the pipes. The door can easily be made smoke-proof after each cleaning. When the fire is much used it would be well to put the rod referred to through the pipe every month or so, as a greasy matter will collect and cake the sides. We think a 5-feet upright pipe will answer, but would prefer it one a foot or two more, that the upper end may stand free of the glass, and that end should be protected with a cowl to prevent rain from freely entering. We have made a fixed cowl by bending a broad slip of tin over the end of the pipe, and tying it there with a wire, so as to allow two outlets for the smoke. Very dry wood should be used for lighting. The combustion must be regulated from the ashpit door, especially after the stove is fairly warmed. A great help to the combustion of the smoke is to have a small opening at the top of the furnace door, from one-eighth to one-fourth of an inch in diameter, to be closed with a stopper at pleasure. This allows a stream of air to pass over the top of the fuel, and smoke and gases are thus burned.

Heating a Cucumber House (*Constant Reader*).—Many fine Cucumbers are grown with the help of a strong brick flue. It is always expensive to use hot water for such a small house as one 12 feet by 9, and a lean-to. We cannot tell you the expense, but a boiler would be about 5 *s.*, and 4-inch pipes, without elbows, would be about a shilling a-foot. To heat such a house for early or winter Cucumbers, you would require a bed from 4 to 5 feet wide, and three pipes beneath the bed for bottom heat, and then you would want from three to four pipes the length of the house for top heat—that is, fully 80 feet altogether. For late spring work less piping would do. For your conservatory, as you cannot have a stoke-hole, you had better have a self-contained boiler, which needs no brick-work round; several are advertised in our pages. If the conservatory is small, you might have an iron stove with a pipe through the roof. Could you not heat the conservatory from some of the lower fires in the dwelling-house? The fireplace in the dining-room, with an iron plate at the back instead of brickwork, would almost keep out frost.

Arrangement of a Greenhouse and Vinery (*X. X. X.*).—The best way to arrange such a small vinery and greenhouse, would be to have a path down the middle, and a platform for plants on each side, as the house is rather narrow to walk round. To lose no space, you could have a wide shelf suspended over the pathway. Both divisions would then look alike. You could store many things below the platforms. Your heating will be sufficient for ordinary purposes. You can grow Cucumbers in the greenhouse in summer, but you must take out your greenhouse plants. You will not have heat for early Cucumbers, neither will you have heat enough in the vinery for early Cucumbers. If you must have the boiler and furnace inside the house, you had better have a Riddell's, Marriott's, or Green's boiler. These will need no brickwork. You must use a little care in lighting and cleaning, and there need be no detriment. We do not know exactly about excavating. Flooring is a matter of taste; some use nice gravel, others tiles, others stone slabs, &c. Tiles look very neat; gravel is easily kept clean.

Cyclamen Culture (*A.*).—The corms of all the species and varieties ought to be covered with soil; they will grow if but partly covered, but they do not succeed so well as when covered from three-fourths to an inch deep with soil. We have no experience of the cultivation of Cyclamens in sand and water in glasses, and we do not think it desirable, even if practicable.

Compost for Alocasia metallica (*J. B.*).—It may be grown either in pots or pans, but we prefer pots. Use a compost of one-half fibrous sandy peat, torn to pieces with the hand and left rather coarse, one-fourth fibrous loam, one-eighth charcoal in pieces from the size of a pea up to that of a hazel nut, and a like quantity of silver sand, the whole well mixed. One-eighth of old dry cow dung may be added with advantage. Good drainage is necessary.

Flax Refuse for Orchids (*Idem*).—It is a good manure, and desirable when partially decomposed for mixing with the compost for plants, in the proportion of one-third. We have no experience of it as a compost for Orchids, but think it a likely material, as they seem to thrive in decayed vegetable matter.

Fuchsias not Flowering (*Idem*).—The tips of the Fuchsia shoots enclosed to us are very weak and poor, we think in consequence of the plants having been kept too dry last winter whilst in a state of rest, the wood probably having shrivelled. A little water ought to have been given to prevent that. Cut them down and encourage the shoots from the base. The sprig belongs, we think, to Abutilon venosum, a greenhouse plant, succeeding in a compost of two parts sandy fibrous loam, and one part leaf soil. Prune the plant in spring, keep it dry in winter, and grow it in a light airy position. It is a fine greenhouse plant for late summer or autumn flowering.

Carrots Splitting (*Tilburstone*).—The cause of Carrots splitting is their growth being arrested by dryness, and they become mature. They ought to be taken up and stored in sand in a cool, rather dry place, for if left in the ground after the first moistening of the soil by rains, they begin to grow and split. The Early Horn and all early Carrots are more subject to splitting than the later ones, as the Long Surrey, the best of all Carrots for winter use.

Mealy Bug on Vines (*A. J. J.*).—The fumigation of the house with burning sulphur will kill the mealy bug, and every living thing in the house. Though, perhaps, it might not kill Vines leafless and in a state of rest, it is an experiment we would not advise. The fumes of burning sulphur are destructive to all vegetable as well as animal life. If you mean by "fumigation with sulphur," the painting of the hot-water pipes or flues with sulphur when they are heated to a temperature not exceeding 180°, nor less than 160°, we see no evil in the proceeding; it will destroy the red spider but not mealy bug. The Grapes being cut, we would syringe the Vines forcibly a few times with water at 140°, and this will to a great extent clean the Vines. As the leaves fall they should be collected and burnt; and when they are all off wash the Vines, after freeing them of the loose bark, with water at 140°, clearing out well all crevices and using a rather stiff brush, but taking care not to injure the eyes. After the Vines are pruned repeat the washing, and scrub every part of the house thoroughly with water as hot as can be borne, and 4 ozs. of soft soap dissolved in every gallon of water. The soap water ought not to be put on the glass. Wash the walls with lime and sulphur in equal parts, employing the soap solution for mixing with. Have all the woodwork painted, and then dress the Vines with a composition formed of sulphur vivum, 1 lb.; fresh lime, 8 ozs.; soft soap, 8 ozs., the whole brought to the consistency of paint by adding the tobacco water of the shops undiluted, or that made by pouring a gallon of boiling water over 4 ozs. of the strongest shag tobacco, covering up until cool and then straining. Apply with a brush, rubbing it well into every crevice. To every gallon, add six drops of spirits of turpentine.

Melon Sowing (*S. S.*).—To have Melons early, the seed may be sown in January, but we do not sow, or if we do, only a few seeds, until the beginning of February. Melons succeed well in pots, but the fruit does not attain the same size as on plants turned out. The most suitable pots are those 11 or 13 inches in diameter. The plants should have a bottom heat averaging 75°; not less than 70°, nor exceeding 80°. The top heat may be from 65° to 70° at night in the early stages of their growth, from 60° to 65° further on, and 70° or 75° by day without sun, and from 80° to 85° or 90° with sun and abundance of air.

Wintering Caladiums (*Idem*).—The leaves will decay when the growth is complete, and its completion may be promoted by keeping up a good heat and withholding water, but not allowing the soil to become very dry; even after the plants have died down, a little water should be given occasionally. If the soil be allowed to become dust dry, the roots are apt to become farinaceous, and to rot when water is applied in spring. When at rest they should have a temperature of not less than 60°. From 60° to 65° from fire heat, or at night, will be suitable, though the temperature may at times be lower.

Planting Tea-scented Noisette Roses (*B.*).—"There are no Roses equal to them for earliness, continuity, and lateness of blooming. The most successful are Solfaterre, Gloire de Dijon, Triomphe de Rennes, and Céline Forestier. The first must have a south wall; the others will do well anywhere, with or without a wall, on their own roots, on the Manetti, or on the Briar. I have not Solfaterre here, but the other three are here, and the garden is now (September 13th), full of Yellow Roses. Solfaterre and Céline Forestier require a greater height of wall than 7 feet. For such a height have Gloire de Dijon and Triomphe de Rennes. Céline Forestier is the best of all Roses for a standard. This and Gloire de Dijon are the only Roses that I keep on a Briar; all the others are on Manetti or their own roots.—W. F. Radclyffe."

Cutting-back an Old Yew Hedge (*Alice*).—The best time to cut back the Yew and all evergreens is in spring, before they begin to grow. You may cut it back as much as you like; it will push shoots again from the stem and branches, of whatever thickness or age, and in a short time become quite green again. It is the best of hedge shrubs.

Plants for South Aspect of House (*Idem*).—Akebia quinata, lilac pink; Berberidopsis corallina, red; Billardiera longiflora, red; B. scandens, purple; Escallonia macrantha, red; Garrya elliptica, greenish yellow; and Ligustrum japonicum, white. Common ones are Crataegus Pyracantha and Cotoneaster microphylla, both with white flowers, succeeded by red berries, and having splendid deep green foliage, giving a close mantling.

Select Gooseberries and Planting (*E. R. P.*).—Of the small high-flavoured sorts, Champagne, Yellow Champagne, Early Green Hairy, Keens' Seedling, Red Warrington, and Pitmaston Green Gage. Of the Lancashire, or large sorts, red—Hopley's Companion, Atlas and Crown Bob. White—Sheba's Queen, Wandering Girl, and Ostrich. Green—Thumper, Angler, and Conquering Hero. Yellow—Broom Girl, Marigold, and Husbandman. The best time to plant them is early in November, or as early in autumn as the leaves have fallen. The ground should be well and deeply dug or trenched, and a 3-inch dressing of manure mixed with it. The manure should be well rotted; farmyard manure is best, though stable manure will do, but if the soil is light, preference should be given to cow dung, as it is cool, and retains moisture better than others.

Currants for Walls (*Idem*).—*Red:* Red Dutch, Knight's Early, Knight's Large, and Houghton Castle or Victoria, are the best Red Currants. *White:* White Dutch is the only really good White Currant. They require the same preparation of the soil as Gooseberries.

Replanting Vines (*A Subscriber*).—By replanting the Vines at the end of this month you will obtain a certain amount of root action this autumn, and in that respect they will have an advantage over those planted next March or April. Nevertheless, we consider the latter a better time to lift and plant Vines than the former. If you move them now, no water should be given this autumn beyond that needful at planting to settle the soil about the roots, and they ought to have a gentle heat, putting on fire in the day only, with abundance of air, until the leaves are all off. It will be well if you can remove them and get the wood properly ripened without inducing second growth, but we doubt that as the border is outside. We recommend you to plant in March.

Destroying Leather-jackets (*Idem*).—We do not know of any other

mode of destroying them except hand-picking. It is a tedious but certain mode of clearing them off.

Various (*S. P.*).—Beaumontia grandiflora is a subscandent evergreen stove plant, with whitish flowers in June. Pot it in spring in one-half sandy peat, one-fourth fibrous loam, one-eighth charcoal, in pieces not larger than a hazel nut, and one-eighth silver sand. Keep it moist, and do not overwater, or rather water sparingly, until the roots are working freely in the fresh soil, then water freely. In winter keep the plants dry. For the culture of Dioonea muscipula, see vol. xvi., page 247. Nepenthes are ornamental plants, bearing pitchers at the ends of the leaves when vigorous. They require a moist stove, and a compost of fibrous peat, chopped sphagnum, charcoal or broken pots, in equal parts, well mixed. Drain the pots well, and set them in a saucer of water when the plants are growing, keeping the atmosphere very moist. In winter keep the plants drier. Afford them partial shade in summer. Gymnostachyum Pearcei and Verschaffeltii grow in large shallow pans, in a compost of one-half sandy fibrous peat, one-fourth turfy light loam, and one-eighth broken charcoal, the rest crocks broken rather small, and silver sand. Drain the pans well, keep both the soil and the atmosphere moist in summer, and avoid wetting the foliage by syringing. Train the shoots over the surface of the pans, and in winter keep rather dry. They require a stove. Cut down the Cyanophyllum magnificum to the eyes next the soil in February, make a cutting of the shoot, and you will have a better old plant, and a young plant which, with good cultivation, will be finer than it before autumn. Charcoal is best made from Oak, but Elm, Ash, and all hard woods are good for the purpose.

Insects Attacking Peas (*O. W.*).—Your Peas saved for seed have been attacked by the larvæ of the white-shouldered moth, Tinea sarcitella, common in houses. Keeping them in dry sand would prevent the moth from depositing her eggs on them; but care must be taken to cover them to the depth of at least half an inch below the surface of the sand.

Pear Leaves (*E. H.*).—The rust-coloured spots on your Pear leaves are caused by a disease of the tissues of the tree. The "minute eggs," as you miscall them, are vegetable pustules. Possibly they may be caused by insufficient drainage at the roots of the tree.

Names of Fruit (*Rev. E. H.*).—Your Grape is Stillward's Sweetwater. (*J. Hunt*).—Your Pear is Doyenné Blanc.

Names of Plants (*Mary Capstick*).—1, If a Fern, impossible to determine from the scrap sent; 2, Tradescantia virginica. (*J. E., Oswestry*).—An abnormal state of Ulmus montana. (*H. D.*).—Plum crushed, but probably the Woolston Black. 1 and 2, Hibiscus syriacus; 3, Ceanothus azureus. (*T. V. L.*).—Achillea Millefelium. No. (*Lady Hylton*).—Polystichum angulare var. lobatum. (*Devon*).—1, Dactylis glomerata variegata; 2, Molinia cærulea variegata; 3, Nepeta Mussinii; 4 and 5, insufficient for naming—4 (a solitary flower), is a Dracocephalum, probably peregrinum; 5, a Helichrysum. (*M. H.*).—1, Aster puniceus; 2, Sedum spectabile.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending September 14th.

Date.	Barometer.		Thermometer.				Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, AND PIGEON CHRONICLE.

A POULTRY SHOW FOR LONDON.

It has always been a mystery to me why we in London have not our annual poultry, Pigeon, and Rabbit show. We read in the Journal of country towns, some of them with a population of only a few thousands, having their annual shows; of valuable prizes being offered, of numerous entries being obtained, of a good show of birds and Rabbits being the result, and of the whole proving most successful. Here we have nothing of the kind, except one tried this year at Peckham, which I am sorry to hear was financially a failure, owing, no doubt, to its being held in such an out-of-the-way place. It appears there will be no attempt to renew it. This absence of an annual and a successful show cannot be through any want of public interest in fowls or Pigeons. In London and its suburbs are to be found some of our most famous poultry and Pigeon-breeders, our railways connect us with all parts of the United Kingdom, we possess a larger population than any other city, and there is no want of interest in poultry and Pigeon-breeding, for go in whatever direction you may—to the most densely crowded, or to the more aristocratic parts of the metropolis, and you are nearly sure to see or hear poultry or Pigeons. Here we have the best cattle, horse, and bird shows; then why not our poultry show?

What we want is an energetic committee, composed of really practical men, who are acquainted with the management and treatment of birds and Rabbits, and are men of business, who feel an interest in what they have taken in hand, and not men who are only calculating on how much they can get out of the affair, or how much beer or gin they are likely to obtain from this or that successful exhibitor. What is more annoying, or sooner disgusts a man, than to be bothered by a number of half-drunken hangers-on, who follow him, and keep dunning for drink? and yet we often find this at some of our shows. A place for the show should be chosen somewhere in the centre of London, easy of access by rail or omnibus. The time should be during the Cattle Show week, for then we have our country cousins with us, who would gladly patronise our show, both by sending us their birds for exhibition, and by their own presence. I venture to say a show held about that time, well managed, would turn out a success, and would become the first show in the kingdom.

My reason for writing is to try to ascertain the feelings of some of your readers, also to induce some of our well-known breeders to take the matter up. If a meeting of those who feel an interest in such an exhibition could be arranged, something might be done.—An Amateur.

WHITBY POULTRY SHOW.

The thirty-fifth annual Show of the Whitby Agricultural Society was held September 8th, in a field admirably adapted for the purpose. The day was all that could be desired, and there was a much larger attendance than in former years. The receipts at the gates were upwards of £122, being about £37 more than last year.

The poultry entries amounted to 279, a less number than last year, but the quality of the birds shown in most of classes was first-rate. The Show was in all respects well managed by the Secretary, who is ever ready to give any information.

The *Dorkings* were of very middling quality. The first-prize chickens were the best in the two classes, and a pen belonging to Mr. Burn would have been second but for the cock having spurs on the outside of his legs; in other respects it was a good pen. The *Spanish* were not so good as we had expected to see, but the prize pens were fair. The prize pens of *Game* were very good and in good condition; the rest of the classes only of average merit. The *Cochins* were not good. The *Brahmas* were much better than the Cochins, and all were Dark. Of *French* fowls, Mr. Quibell's pen of Houdans was good. The second prize was awarded to Crève-Cœurs. Many of the *Hamburghs* were very good, more particularly the chickens. Mr. Walker showed some very good pens, also Mr. Holmes. Some of the *Bantams* were very good.

The Rouen *Ducks* were an excellent class, and fifteen pens competed; four were highly commended. Some of the Aylesburys were very good, also the Black East Indians, which had a separate class. In the class for "Any other variety," both prizes went to Carolinas, the Mandarin being quite out of plumage, but in other respects very good. The *Geese* and *Turkeys* were very good.

The *Pigeons* were good, and attracted great attention from the lady visitors. The *Rabbits* were not numerous, but some good specimens were shown.

Dorking.—1, H. Smith. 2, W. Bearpark. *Chickens.*—1, G. F. Wormald. 2, Rev. G. Hustler.

Spanish.—1, G. Holmes. 2, T. E. Pymad. *Chickens.*—1, S. Burn. 2, J. B. Stephenson.

Game.—1, H. M. Julian. 2, J. Walker. *Chickens.*—1, G. Penuder. 2, T. Blackburn.

Cochin-China.—1 and 2, T. H. Readman. *Chickens.*—1, T. H. Readman. 2, E. Noble

Brahma Pootra.—1, E. Leech. 2, J. Walker. 3, C. Layland.

French.—1, W. O. Quibell. 2, C. Layland.

Hamburghs (Golden-spangled).—1, G. Holmes. 2, J. Walker. *c*, G. Garbutt.

Hamburghs (Silver-spangled).—1, G. Holmes. *Chickens.*—1 and 2, J. Walker.

Hamburghs (Golden-pencilled).—1, J. Walker. 2, G. Holmes.

Hamburghs (Silver-pencilled).—1, G. Holmes. 2, T. H. Readman.

Chickens.—1, J. Walker. 2, J. Webster. *c*, T. H. Readman; G. Garbutt; J. Walker.

GAME BANTAM.—1 and 3, W. F. Entwisle. 2, J. Duggleby.

BANTAM.—1 and 2, T. C. Harrison. 3, S. & R. Ashton.

BANTAMS (Any other variety).—1, R. Loft. 2, G. D. Yeoman. 3, W. Usherwood.

DUCKS (Black East India).—1 and 2, S. Burn.

DUCKS (Aylesbury).—1, E. Leech. 2, W. Stonehouse. *c*, O. A. Young; W. Stonehouse.

DUCKS (Rouen).—1, G. Garbutt. 2, — Stott. *c*, O. A. Young; Mrs. C. Stamper; T. P. Scoby.

DUCKS (Any other variety).—1, J. Walker. 2, T. C. Harrison. *hc*, S. Burn.

GEESE.—1, Rev. G. Hustler. 2, — Stott. *hc*, E. Leech; O. A. Young.

GEESE.—1, O. A. Young. 2, Rev. G. Hustler. *hc*, J. Wilkinson.

TURKEYS.—1, O. A. Young. 2, Mrs. W. Ward. *c*, J. H. Allen.

TURKEYS.—1, J. Plews. 2 and *c*, Mrs. W. Ward.

ANY VARIETY.—1, W. English. 2, R. E. Stratford. 3, G. Holmes.

PIGEONS.—*Pouters.*—1 and 2, E. Horner. *Tumblers.*—1, J. Hawley. 2, H. Yardley. *Carriers.*—1 and 2, E. Horner. *Fantails.*—1, J. Hawley. 2, J. F. Loversidge. *c*, E. Horner; W. H. Tomlinson. *Jacobins.*—1 and 2, E. Horner. *Trumpeters.*—1, J. Crndale. 2, E. Horner. *c*, J. Hawley; R. Wilson. *Barbs.*—1 and 2, E. Horner. *Any other Variety.*—1, J. Hawley. 2, R. Wilson. *c*, H. Yardley. *Selling Class.*—1, Hudson & Burnip. 2, C. Gravil.

RABBITS.—*Yellow and White, or Tortoiseshell.*—1, C. Gravil. 2, R. Hudson. *Any other Variety.*—1, G. S. Hudson. 2, R. W. Andrew. *Selling Class.*—1, C. Gravil. 2, W. Donkin.

JUDGES.—Mr. Adams, of Beverley; and Mr. James Dixon, of Bradford.

MARKET DRAYTON POULTRY SHOW.

THE entries for this Show, held on the 10th inst., were unusually limited, and it appears that the time of holding the Exhibition was known to but very few poultry amateurs. We would suggest another season more publicity, and cannot but imagine, were the Show properly advertised, the entries might easily be quadrupled. There were, however, many most excellent pens. The Duke of Sutherland's two pens of *Hamburghs* were especially good. There were also some first-rate *Game*, *Crève-Cœurs*, *Dorkings*, and *Dark Brahmas*. The *Geese* and *Ducks* were one of the chief features of the Market Drayton Show. Perhaps another year the most beneficial rule would be to let the competition be open to birds of any age. It would beyond question greatly increase the number of entries, and prevent the annoyance several exhibitors felt on this occasion from the disqualification of adult specimens, as this Exhibition was restricted exclusively to chickens. The forenoon of the Show day was fine, but the evening was most unfavourable.

GAME COCK.—1, R. Ashley, Nantwich. 2, W. Perrin, Nantwich (Brown Red). *c*, T. Eaton, Audlem (Cheshire Pile); J. Platt, Swanlow.

GAME (Black or Brown Red).—1, R. Ashley. 2, T. Eaton (Brown Reds). *hc*, G. F. Ward, Wrenbury, Nantwich (Brown Reds). *c*, W. Miller, Wybonbury, Nantwich (Brown Reds).

GAME (Any other variety).—1, R. Ashley. 2, T. W. Jones, Wellington, Salop (Duckwings).

DORKINGS.—1, Viscount Hill, Hawkstone (Silver-Grey). 2, J. Edwards, Wellington (Greys). *c*, J. Edwards (Greys); Miss E. Williams, Henllys, Berriew (White Rose-combed).

HAMBURGHS (Gold or Silver-spangled or Pencilled).—1 and 2, Duke of Sutherland. *hc*, T. May, Wolverhampton (Golden-spangled).

ANY OTHER DISTINCT VARIETY.—1 and *hc*, W. B. Etches, Whitchurch (Dark Brahma Pootras). 2, Miss E. Williams (Crève-Cœurs). *c*, F. E. Hume, Market Drayton (Game Bantams).

DUCKS.—1, Mrs. M. Hornby, Swanlow (Aylesbury). 2, H. B. Clive, Market Drayton (Aylesbury). *c*, H. R. Corbet, Adderley Hall (Buenos Ayres).

GEESE.—1 and 2, W. Mate, Market Drayton. *hc*, J. Edwards; H. Pooler, Calvington, Newport (White).

TURKEYS.—1, H. R. Corbet. 2, Viscount Hill (American).

Edward Hewitt, Esq., of Sparkbrook, Birmingham, was the Judge.

LEIGH POULTRY SHOW.

THIS was an admirable and well-conducted Show, and the entries embraced a large number of the best pens of poultry. The weather on the day of the Show, the 8th inst., was exceedingly fine, and the attendance a great improvement on that of previous years. From some delay in transit, a large number of most excellent pens did not arrive until long after all the prizes had been awarded and the final returns made by the Judges, although the Committee, hearing of the delay, awaited their arrival till some hours after the time appointed to commence judging. Quite unexpectedly, one of the best filled of any of the classes, both in respect to numbers and quality, was that for *Polands*. These were in first-rate feather, and comprised all the general varieties of Polands, and the visitors were much interested in so perfect a display.

GAME (Black-breasted Red).—1, C. W. Brierley, Middleton. 2, J. Halsall, Ince.

GAME (Brown Red).—1, C. W. Brierley. 2, R. & W. Barton, Westleigh.

GAME (Any other variety).—1, C. W. Brierley. 2 and *c*, J. Halsall (Piles and Duckwings).

SPANISH (Black).—1, C. W. Brierley. 2, Burch & Boulter, Sheffield. *hc*, W. Gamon, Chester; N. Cook, Chowbent.

COCHINS (Buff).—1 and 2, W. A. Taylor, Manchester.

COCHINS (Any other colour).—1 and 2, W. A. Taylor (Partridge). *hc*, E. Shaw, Plas Wilmot, Oswestry (Partridge).

BRAHMA POOTRA.—1, E. Leech, Rochdale. 2, C. Leyland, Morrisbrook, Warrington.

DORKINGS.—1, J. Stott, Healey, Rochdale. 2, E. Shaw. *hc*, J. Partington, Leigh. *c*, E. Leech.

HAMBURGHS.—*Golden-pencilled.*—1, T. Wrigley, Tonge Hall, Middleton. 2, H. Pickles, jun., Earby, Skipton. *hc*, W. Clayton, Morton Bank, near Keighley. *c*, Burch & Boulter. *Silver-pencilled.*—1, H. Pickles, jun. 2, J. Platt, Deane. *Golden-spangled.*—1, H. Pickles, jun. 2 and *hc*, T. Walker, jun., Denton, Manchester. *Silver-spangled.*—1, W. A. Turner, Manchester. 2, H. Pickles, jun.

POLANDS (Any variety).—1, H. Pickles, jun. 2, J. Partington (Silver-spangled). *hc*, H. Smith, Westleigh; W. Gamon, Chester; J. Partington (Silver-spangled). *c*, T. Wakefield, Golborne; W. Gamon.

GAME BANTAMS.—1, J. Morris, Rochdale. 2, J. Henshall, Salford. *c*, G. Anderton, Accrington.

BANTAMS (Any other variety).—1, S. & R. Ashton, Mottram. 2, Miss N. Platt, Deane (White rose-combed). *c*, T. Walker, jun (Black); H. Pickles, jun.

ANY OTHER DISTINCT BREED.—1, C. Leyland (French). 2, T. Walker, jun (Black Hamburghs).

GAME (Any variety).—*Cock*—1, C. W. Brierley. 2, P. West, Abram, Wigan. *Cockerel*—1, J. Eaves, Prescott. 2, J. Halsall (Black Red). *hc*, A. Haslam, Close Lanes, Hindley.

BANTAM (Any variety).—*Cock*—1, J. W. Morris. 2, Harewood & Buckley, Accrington (Black Red Game). *Pullet.*—1 and *c*, A. Haslam. 2, J. Thomason, Westleigh. *hc*, J. Halsall (Black Rod Game).

SELLING CLASS.—1, C. W. Brierley, Middleton. 2, S. Farrington, Chatmoss, Astley. *hc*, E. Shaw.

DUCKS (Aylesbury).—1, H. Pickles, jun. 2, E. Leech.

DUCKS (Rouen).—1, E. Leech. 2 and *hc*, W. Gamon, Chester.

DUCKS (Any other variety).—1 and 2, C. W. Brierley. *hc*, S. & R. Ashton, Mottram.

GEESE (Any colour).—1, E. Leech. 2, H. Ratcliffe, Fearnhead.

TURKEYS (Any colour).—1, E. Leach. 2, J. Bent, Bradshawleach, Pennington.

EXTRA STOCK.—Extra prize, J. Lang, Hindley (Fallow and White Doe Rabbit).

Mr. Edward Hewitt, of Sparkbrook, Birmingham, and Mr. Elijah Smith, of Middleton near Manchester, were the Judges.

MORPETH POULTRY SHOW.

THE following awards were made at this Show, held on the 9th inst.:

GAME (Any variety).—1, G. Taylor, Sleekburn (Black Red). 2, M. Bullock, Morpeth (Black Red).

GAME (Black-breasted or other Reds).—1, D. Nichol, Morpeth. 2, M. Bullock.

GAME (Any other variety).—2, D. Nichol.

DORKINGS (Any variety).—1, J. Sim, West Cramlington. 2, J. O'Leary, Morpeth.

COCHIN-CHINA (Any variety).—1, J. Dodds, Netherton (Buff). 2, T. Fenwick, Netherton New Row. *hc*, J. Yellowley, Barrington Colliery (Partridge).

BRAHMA POOTRAS.—1, J. Stalker. 2, Mrs. Davie, Hepscott Red House.

SPANISH.—1, Cup, and 2, J. Stalker.

HAMBURGHS.—*Golden-spangled.*—1, W. Dixon, Choppington. 2, G. Stalker. *hc*, G. Johnson, Choppington. *Silver-spangled.*—1, Stephenson and Cheyne. 2, Cook & Stalker, Bebside. *hc*, C. Armstrong, Bebside; D. Cheyne. *Gold or Silver-pencilled.*—2, W. Hall (Golden-pencilled).

ANY OTHER VARIETY EXCEPT BANTAMS.—2, T. Thornton, Bebside (Black).

GAME BANTAMS (Black-breasted or other Reds).—1 and 2, G. Dowie, Netherton Colliery (Black-breasted Red). *hc*, W. Ramsay, West Cramlington (Black-breasted Red).

ANY OTHER VARIETY EXCEPT GAME.—1, T. Thornton (Black). 2, J. Robson, Bebside (Sebright). *c*, W. J. Thompson, Woodhorn Manor (Black Bantams).

DUCKS.—*Aylesbury.*—1, Mrs. Davison, Eastmills. 2, D. Nichol. *Rouen.*—1, Miss F. Wilson, Woodhorn Manor. 2, Mrs. Davie. *Any other Variety.*—1, J. Simm, West Cramlington. 2, Mrs. Davie.

SELLING CLASS.—1, J. Stalker (Black Spanish). 2, D. Cheyne (Golden-pencilled Hamburghs). *hc*, J. Neasham (Golden-spangled Hamburghs); W. Cowens, Morpeth (Silver-spangled Hamburghs).

Cup for best pen in the show.—J. Stalker.

JUDGE.—Mr. Shorthose, Hartford Bridge.

CROOK POULTRY SHOW.

THIS took place on September 8th, and was much larger than any previous Show held at the same place. The winning *Spanish* and *Hamburghs* were in splendid condition.

GAME (Black-breasted or other Reds).—1, W. Bearpark, Ainderby. 2, A. Buglass, Carville.

GAME (Duckwings or other Greys).—1, J. Robson, Bishop Auckland. 2, R. Wilkinson, Stanhope. *Chickens.*—1, R. Williamson. 2, T. Butterfield.

SPANISH.—1, W. Bearpark. 2, A. Young. *hc*, Mrs. Sanderson. *c*, W. Burn, Hope Street. *Chickens.*—2, A. Buglass.

DORKINGS.—1, W. Bearpark. 2, T. Hymers, Birtley. *hc*, J. T. Prond, Bishop Auckland. *c*, J. Armory, Gibbet Hill, Witton. *Chickens.*—1, W. Bearpark. 2, A. Young. *hc*, J. Armory. *c*, Miss Hull, Ball Hill, Brancepeth.

BRAHMA POOTRAS.—1, T. W. Kilburn, Bishop Auckland. 2, W. Bearpark. *hc*, Rev. G. Lloyd, Crook. *c*, Miss D. D. Shafto, Brancepeth Rectory. *Chickens.*—1, G. Bell, North Beechburn. 2, T. Mitchell. *c*, J. Bird, Brancepeth.

HAMBURGHS (Golden-pencilled).—1, M. Ridley, West Peakfield. 2, J. Wilson. *Chickens.*—1, W. Bearpark. 2, R. Moore.

HAMBURGHS (Silver-pencilled).—1, J. Taylor, Bollihope. 2, M. Ridley. *Chickens.*—2, W. Whitfield.

HAMBURGHS (Golden-spangled).—1, W. Bearpark. 2, J. Potts. *hc*, J. Sanderson, Wolsingham. *c*, G. Bruster, Byers Green. *Chickens.*—1, R. Moore, 2, T. Mitchell.

HAMBURGHS (Silver-spangled).—1, R. Moore. 2, T. Hymers, Birtley. *Chickens.*—1, W. Bearpark. 2, R. Moore. *c*, J. Gardner, Frosterley.

BANTAMS.—1. A. Buglass, Carville. 2, T. Mitchell, Mount Pleasant.
GEESE.—1, M. Heslop, Harthope Mill. 2, Mrs. Hedley, Quarry Burn.
DUCKS (Aylesbury).—1, G. Allison, Park Wall. 2, M. Harrison, Warter, Pocklington. *hc*, A. Young, Driffield; Mrs. Sanderson.
DUCKS (Any other breed).—1, A. Young. 2, J. Emmerson, Low Jeffies.
TURKEYS.—1, G. Thompson, Bog Hole Farm. 2, Mrs. Sanderson, Bradley Hall.
EXTRA CLASS.—1, Miss D. D. Shafto (Cochin-China). 2, J. Hardy (White Cochin chickens).
PIGEONS.—1, R. Thompson, Sunnybrow. 2, G. Adamson.
JUDGE.—Mr. F. Greathead, Darlington.

DOVER FANCY RABBIT SHOW.

THE fourth half-yearly Show was held, September 1st, at the Wellington Inn, Biggin Street. The show of prize Rabbits was exceedingly good, and demonstrated that there were many strong and practical breeders connected with this now well-known society. It gave great satisfaction to the numerous company that attended on the occasion.

LENGTH OF EARS.—Mr. Stanton, fawn doe; 21¾ by 5 inches; weight, 9 lbs. 6 ozs. Mr. Wherwell, fawn doe; 21½ by 4¾ inches; weight 6 lbs. 9 ozs. Mr. Burton, yellow and white doe; 21 inches; weight 9 lbs. 4 ozs.
ALL PROPERTIES.—1, Mr. Jasper, black and white buck; length of ears, 19½ by 4¾ inches; weight, 4 lbs. Mr. Barwick, yellow and white doe; 21 by 4¾ inches; 7 lbs. Mr. Corry, tortoiseshell doe; 20 by 4¾ inches; weight 8 lbs. 5 ozs. Mr. Everest, grey and white doe; 18½ by 4½ inches; weight, 6 lbs. Mr. Thorne, fawn doe; 20¾ by 4¾ inches; weight, 6 lbs. 12 ozs. Mr. Pritchard, fawn buck; 20¼ by 4½ inches; weight, 8 lbs.
WEIGHT.—Mr. Young, tortoiseshell doe; 20 by 4½ inches; weight, 10 lbs. 6ozs.

The Judges were Messrs. Whorwell, Stanton, Burton, and Everest. —(*Dover Chronicle.*)

SUBURBAN PIGEONS AND FOWLS A CENTURY AND A HALF AGO.

GAY, in his "Epistle to the Earl of Burlington," in which he so amusingly details his equestrian ride to Exeter, says—

> "Then Turnham Green, which dainty Pigeons fed,
> But feeds no more, for Solomon is dead.
> Three dusty miles reach Branford's tedious town—
> For dirty streets and white-legg'd chickens known."

A foot-note says, "Solomon was a man famed for feeding Pigeons." Is anything known about him? and are chickens still a Brentford export?—VECTIS.

"DROPSY" IN BEES.

MR. WOODBURY in an article which appeared in the Journal of December 26th, 1865, described as a new disease under the name of "dropsy," a malady which he supposed to have been previously unnoticed by apiarian writers. To this view of the complaint I took exception at the time, believing it to be identical with what had long been known as dysentery; but I now confess I was altogether in error, and I might at once have perceived my mistake if I had given due consideration to his statement that, "all through spring and during the finest summer weather the ground in front of the hives was perpetually covered with hundreds of disabled and dying bees, which crawled about in all directions." Dysentery seldom if ever attacks bees during the finest summer weather, and when a hive is afflicted with it, a few fine days are generally sufficient to restore it to health.

This disease may be said to be at an end as soon as the overloaded bees have discharged themselves; but it is not so in "dropsy," where the parting with its contents gives the afflicted bee no relief. Although the general characteristic of the complaint is a swollen abdomen filled with a watery fluid, there are also amongst the sufferers great numbers with little visible enlargement that are yet unable to do more than hobble over an inch or two of ground and make a feeble movement with their wings. In crawling out of the hive they appear very sensitive to cold, and will often turn back.

Their bodies, too, have a glistening appearance as if covered with perspiration, forcibly reminding one of a plague of former days called the "sweating sickness." But as Mr. Woodbury has given so full and so accurate an account of the malady in the article referred to, I shall briefly state what recently came under my observation, as I think it corroborates the truth of what he has there narrated, and any tyro in bee-keeping may put in practice the simple mode of cure prescribed.

My first experience of "dropsy" commenced in January last. When walking round my apiary towards the close of the month, I found one of the hives in a state of fever-heat, and buzzing as loudly as it often did in summer. The outer glass, which should have been cold, felt quite warm to the touch, and the bees showed evident symptoms of distress by retiring from the entrance the moment they approached it. I did not at the time apprehend mischief, but in the course of a few days a fearful mortality set in. Bees unable to fly hobbled to the edge of the landing-board, and fell to the ground. On elevating the hive I found the board much soiled, and covered with hundreds of dead and dying. These were immediately cleared-off, the board was washed and dried, and the first favourable opportunity seized for feeding with honey and port wine, which was quickly deposited in the combs. But this nostrum, although a fine day occurred at intervals, allowing such bees as were disposed to go out for an airing, had no effect on the health of the hive. All through February and March the daily death-rate would average two hundred.

The hive had been in splendid condition, and was not only full of bees on the 28th of January, but three of its combs were filled with brood in all stages. On the 19th of March the population was reduced to a mere handful, covering only a portion of two combs. In the short space of six weeks I am persuaded more than 10,000 bees perished, and I conjecture that the whole of the old inhabitants died-off, and that the young bees coming forward in the early part of February alone survived. Egg-laying was entirely suspended, and at the date last mentioned, there was no brood, save two, which were ready to leave the cells. I gave up the hive as lost, but in the beginning of April a bee might be seen to go out occasionally and return with pollen. Contrary to all expectations the hive rallied, its progress towards prosperity was amazingly rapid, and on the 30th of June it was able to send out a good swarm.

Though I give an account of the ravages made in this single hive only, I must add that the malady in question attacked other hives successively in March, April, and May. In two of them the queens perished. One hive in particular escaped a visitation till the middle of May. On the 19th of May, when I left home for ten days, it promised to swarm before any of its neighbours; but when I returned on the 30th I found it one of my weakest, and the ground in front of it literally covered with thousands upon thousands of dead bees. Towards the middle of June I found on examination the brood in two frames, which the small and reduced population could not cover, quite dead, and some of it in a decaying state. A drone comb, which was empty, intervened between these two frames and the other brood combs. I left these frames containing decaying brood in the hive, and I am happy to say that on making an inspection of them on the 19th of August, no evil results had followed.

Owing to the late period of the season when the hive in question was seized with dropsy, there was no return from it in the shape of supers or honey, but it recovered sufficient strength to enable it to lay up ample store for the winter, and it is now as populous as could be desired. There were two swarms among my early casts that carried the complaint with them, but they threw it off in less than a week. Not, however, until the middle of July did it entirely disappear from my apiary, and its departure could not be said to be due to any remedial measures that were employed on my part. I have now the satisfaction of knowing from an experience extending over five months, that the complaint which Mr. Woodbury described and designated "dropsy," is specifically distinct from dysentery, and that however closely it may resemble the latter in some of its features, it is yet far from being identical with it.

Though I could not be said to have tried the cure recommended by Mr. Woodbury for the malady, I have no doubt it will be found amenable to the process he adopted, which was, after securing the safety of the queen, to remove the hive to a little distance, and plant an empty box in its room. This done, the bees are to be brushed off each comb on to a cloth, and each comb when divested of bees is to be placed in the empty box. As the bees that are able to fly will return to their accustomed stance, the diseased ones will be left to perish, and the hive, thus purified by having the whole separated from the sick, will afterwards enjoy health.—R. S.

P.S.—I forgot to mention in my last, that by letting fall two or three drops of carbolic acid within the hive, swarms might be made to go together peaceably, and an end put to hostilities.

FEROCITY OF INDIAN BEES.

MANY stories have already been related in "our Journal" illustrative of the ferocity of the large Indian honey bee, *Apis dorsata*. To these I now add the following:—

The first is extracted from a note just received from an

Indian officer, at present residing in my neighbourhood:—"In my last letter from India I hear that an officer of my regiment has just arrived in Cashmere after a fearful march through Chumba, where he was attacked by a swarm of bees. He took off his coat, and tried to defend himself with it as long as he could, but the venomous brutes got round him, and he had to execute 'a retrograde strategic movement,' followed by the infuriated insects for four miles and a half, when his powers of 'running drill' being exhausted, he had to give in and let them have their wicked will of him, the natural consequence of which was, that he got fever very badly, and had to be carried into Islamabad in a jampan, constructed of branches of trees and grass rope. Not a bad story of real life in the gorgeous Himalayas! Sweet things, our Indian bees, are they not?"

Another Indian letter says:—"The wild bees of India are very dangerous customers, as they attack any animal that happens to disturb them, and it is even said elephants have died from the inflammation caused by their stings. Two years ago, in Agra, the R——'s lost both their carriage horses at the church door on Sunday morning, and the coachman was very nearly killed too. Fortunately the other people had all left, or it would have been much more serious. Something disturbed one of the nests in the church steeple, and the bees all settled on horses and carriage."

General Sir Andrew S. Waugh, late Surveyor-General of India, who was on the Committee of the Geographical Section of the British Association during its recent visit to our ancient and loyal city, also informed me that these bees were the great enemies of tiger-shooters, for if by any chance, during their progress through the forest, the elephant happened to shake a tree in which was one of their nests, down would come the bees, and off would go the elephant crashing through the jungle in uncontrollable terror, whilst the overhanging branches swept everything and everybody from his back. On mentioning this to the writer of the note first quoted, he fully confirmed it, and described how on one occasion a gentleman, weighing at least 14 stone, and therefore as remarkable for his bulk as his bravery, was discovered in a most unenviable predicament, clinging for dear life, with the wind knocked out of him, to a branch of a tree, some dozen feet from the ground, and from which he was afraid to drop, as much out of regard for his limbs as from the dread of certain imaginary tigers which he fancied were prowling around him in all directions. After assisting him to descend from his uncomfortable perch, it was found that he had been incontinently deposited thereon in the course of an elephantine stampede, produced by bees.—A Devonshire Bee-keeper.

TOMATO SALAD.

As there is every probability of a good crop of tomatoes again, I thought perhaps that some of your readers may be glad to know that, independently of making an excellent sauce and a splendid jam, they also make a most delicious salad, the recipe for which is as follows:—Slice ripe tomatoes very thin into a soup-plate; take a little salad oil, vinegar, ground ginger, pepper, salt, and a little sugar; mix all together, and pour on to the sliced tomatoes.

It may be eaten with fish, hot or cold meat, or cheese. Those who are fond of the taste and perfume of onions may take a very small piece, cut very fine, and add to the above, which is decidedly an improvement if not overdone.—John Perkins, *Thornham*.

OUR LETTER BOX.

Catarrh, or Cold, in Chickens (*J. Y.*).—We believe your chickens are suffering from scorching days and frosty nights. This occasions the catarrh and cough. A slight stimulant will relieve it. Strong beer and camphor are both good. Houses that were only partly ventilated when the glass was at 70°, are more than sufficiently so when it falls, as it has done within the last fortnight, to 34°. Treat your chickens as you would yourself, avoid sudden changes of temperature, and do not neglect the premonitory tickling in the throat.

Golden-spangled Polands—Vertigo (*Cottage Gardener*).—You will find entries of Golden-spangled Polands only at the large shows. They are not remunerative classes, and small shows cannot afford them. Any of the principal dealers will supply them. Fowls suffer from vertigo from deranged insides. In extreme cases, bleed at the root of the comb, you will find the blood black, let it bleed till it becomes florid. When the case permits, it is better to proceed by means of purgatives, none is more effectual than castor oil. Dose, a tablespoonful, to be continued daily till a cure is effected.

Cochin-China Fowls (*S. J. R.*).—Your Cochins, according to your showing, are doing you good service, they lay for three months at the time when eggs are scarcest, and then with only a short interval commence again. You must not expect them, nor any fowls, to do more; but you may improve their diet by giving them meal instead of whole corn. Give them meal composed of two-thirds ground oats, and the remainder ground maize, and the peas and barley alone in small quantities for a change. Lettuce, watercress, a turf of fresh grass, all or any of them, would be better than the cabbage leaves.

Crossing Dorkings (*K. H. B.*).—You can have chickens from your Dorkings much hardier by crossing them with Brahmas. Houdans are not a good cross, because they are non-sitters, and are, therefore, undesirable where table fowls are wanted. Your Brahmas want none of the appliances you mention. If you place perches across your moveable houses they will roost on them. No flooring is so good as hard earth for a poultry house. The straw is dirty and injurious.

Fowls for Confined Space (*Young Beginner*).—Keep Houdans and Brahmas. The former are good winter layers, the latter are good sitters and mothers. June chickens are too late for winter layers. It is more than probable they will not lay till February. You should have chickens hatched in April and May, and to insure a succession of eggs you must have a succession of pullets arriving at their laying ages in due order. You must feed well, but do not give too stimulating diet. Their house should be dry and warm, because secured from draughts, but give no artificial heat. Recollect nothing will make a hen lay in the winter; that is the province of a pullet.

Keeping Poultry Extensively (*Boltonian*).—A thousand fowls will want forty acres—*i.e.*, they want the run of them. Those which have acted as layers through the spring will be too old for table poultry in the autumn. To accomplish what you propose you must never keep a hen more than two seasons. We advise you to try first with a hundred hens. We can give no decided opinion, because we know neither the locality nor the market; but, as a rule, if the land must be rented, and all necessaries bought, we do not think you will find it profitable. We shall be happy to answer any plain questions you may put to us.

Exhibiting Spanish Fowls (*Spaniard*).—Our experience does not tally with yours. We have Spanish hens that are now getting well through their moult, their combs becoming redder every day. We have about a score of them, and shall be disappointed if they are not all in fine condition in November. The only treatment we know of, is to confine them in a three-parts darkened place for a week before they are exhibited. This tends very much to develope the comb, and to hurry on condition. Feed on soft food, varied with a few white peas.

Diarrhœa in Fowls (*Bubo*).—In reply to your query we should advise you to do that about which you hesitate—namely, to give a copious dose of castor oil on the first symptom of diarrhœa, follow it with broad and milk, or bread and ale, and avoid any description of hard food.

Wakefield Poultry Show.—We are informed that in the "Selling class" for Pigeons, the second prize was not awarded to Hudson & Burnip, but to Mr. E. Walker, Leicester

Middlesbrough Poultry Show.—We are informed that Mr. Calvert obtained first and second prizes for White Cochins, and Mr. G. H. Procter first and second for Buff Cochins; also that Mr. C. Layland, of Morris Brook, Warrington, took the first prize for Brahma Pootra chickens, and not Mr. Dawes.

Feeding Young Guinea Fowls and Bantams (*A. B.*).—We cannot see that your Guinea fowls lack anything necessary for health. Give them some oatmeal mixed with warm milk, and some onion tops or some garlick chopped up and mixed with it in good quantities. Young Bantams require chopped eggs, groats, bread and milk, curd, and waste meat cooked and chopped fine. All chickens want grass, and must have dust.

Old-fowl Pie (*Old Cock*).—Cut the old cock in pieces in proper joints, collect all the odd scraps of meat you have; anything is good enough that is sweet and clean—remnants of legs or shoulders of mutton, pieces of knuckle, shreds of bacon, lean of ham fat of neck or loin of mutton, all cut in pieces. Take an oval or a round dish of earthenware with a lid, and a hole through the handle to allow the steam to escape. Old crusts are acceptable. If you can, prepare the dish by lining it with thin slices of bacon all round and at bottom; it is an improvement. Then begin to lay in the meat, piece by piece, till the dish is full; place some slices of bacon on the top, pour in water till the vessel is full, put on the lid, tie it down, and leave the dish in a slack oven all night. Take it out in the morning, and put it in a cold place that it may set thoroughly. When cold you will find all the water has become gravy, and the odds and ends are set in jelly. It can be more expensively made. We shall treat of that hereafter. (*E. P. P.*).—See the preceding answer. You may keep hens till they are three years old. Cocks the same. You may keep hen Turkeys longer. Ducks should not be kept after two years, and in all breeds it is profitable and advisable to change the male frequently.

Various Diseases in a Pigeon Loft (*N. Y. Z.*).—We are puzzled to understand the cause of such a varied and general state of disease among your Pigeons. With strict cleanliness, good food, pure water in clean vessels, no crowding, and exercise, Pigeons have rarely any diseases. Open the boils and dress with weak alum and water. Perhaps the Indian corn being mouldy and mothy may be part of the cause; but we should incline to think that your loft has become poisoned by long use, and that removal of all the birds for a time, and a thorough lime washing, would be best. Mix fresh loam and salt, and let the birds peck at it. Wing disease is sometimes cured in its earlier stages by applying iodine paint, to be had of any chemist. Are the water-vessels perfectly clean and in good order? There is no known cure for "going light."

Pigeon Laying Four Eggs (*J. Scott*).—We believe it is rare for a Pigeon to lay four eggs, and still more rare that she should hatch three young ones. Some years since we had a bird that laid three but hatched only two. We have now a Fantail cock which has two wives; he pairs with each hen and they sit in adjoining nests, but only one manages to hatch young. The first wife was for a time truly jealous and beat the second, but now the two matrons are good friends, and each looks on unconcerned at the endearments of the other with her lord. We may add that these Mormonite birds did not come from the Salt Lake City!

Honey (*M. S.*).—Messrs. Neighbour & Sons, and Messrs. Fortnum and Mason, are extensive dealers in honey.

POULTRY MARKET.—September 15.

The prevalence of hot weather makes any quotation of prices a thing more likely to mislead than to help. At such times much is sold at a heavy sacrifice, while a few choice articles make good prices. The proportion of old Partridges is still very large, and the young birds are small. Grouse are rather more plentiful.

WEEKLY CALENDAR.

From observations taken near London during the last forty-two years, the average day temperature of the week is 65 7°; and its night temperature 44.1°. The greatest heat was 82°, on the 25th, 1832; and the lowest cold 23°, on the 28th, 1836; and 29th, 1842. The greatest fall of rain was 1.68 inch.

FORCING PLANTS.—No. 1.

FORCING is compelling plants to grow and flower at unnatural seasons. It is giving them a temperature that will cause them to grow and flower some weeks or months before their natural season. The term is not generally applied to plants which require the temperature of a greenhouse or stove, but many of the inmates, by increasing the temperature, are brought into flower much earlier than if it were no higher than sufficient to make them bloom at their natural time. When a plant receives more heat than is needful for its healthy growth, and for flowering at its natural season, it is forced. To keep up in a greenhouse during January and February a temperature of from 50° to 55° at night is forcing, which is not the object of the structure, the natural temperature for its occupants during these months being from 40° to 45° at night. If the plants are required to bloom at an earlier period than usual, and there are others to come in afterwards at their natural season, then the forcing is desirable, as it affords a longer continuance of bloom. It is also forcing when stove and other plants requiring in our climate artificial heat, are made to flower out of their natural season by the application of more heat than they would otherwise need.

To plants which must have artificial protection and heat at all times, or at certain times only, forcing is not so injurious to future growth and flowering as it is to those most generally forced—viz., hardy plants.

Greenhouse and stove plants required to bloom earlier than usual ought to have the previous growth well perfected, and somewhat in advance of plants intended to bloom at their natural season. They should be allowed as long a period of rest as possible, and be kept as cool and dry as they safely can be, before they are forced into growth and flower. They ought to experience the ripening influence of autumn, and the rest consequent on the cold of winter. If this rest he afforded them, as it may be to a great extent by well maturing the growth by an abundance of light and air, and then removing them to a cooler place, and keeping dry, an approach to the natural rest of the plants will be made; they will start into new growth strongly, and the flowers produced will be hardly inferior to those of plants not forced; indeed, in some cases they may be superior. It is scarcely worth while forcing plants with the growth not well matured, and not well set with buds, or which are not in good health, and have not had a proper preparation. The best subjects only ought to he selected for forcing, and so well is this done that in many, I may say most, instances the forced plants are generally good, whilst the failures are found among plants left to bloom at their natural season. A plant well bloomed in February shows greater skill than one no-better flowered in May. Dr. Lindley, I believe, wrote that "forced flowers are always less beautiful and fragrant than those perfected at their natural periods." Rarity is good, but excellence is best; and when we have the last combined with the former, as we often have in forced plants, I can hardly coincide with Dr. Lindley's other deductions—viz., "It is desirable, at the very least, to devote as much effort and expense to obtain superior produce [flowers] at accustomed times, as the procuring it unseasonably." A Rose is undoubtedly very beautiful and fragrant in June; in January it is both, and also rare, giving it increased value. If the expense and effort to produce the latter were lavished on the former, would it be any more beautiful or fragrant?

Had we been told that forced flowers are not to be had as beautiful and fragrant as those at accustomed times, without selecting the best and finest plants, using due preparation, and better means for flowering them than needed for those blooming at their natural season, it would have been a cause of giving in gardens what are much needed—light, airy forcing houses, instead of having to grow plants required to bloom unseasonably along with those that are to flower at accustomed times. Skill can do much, but even skill will fail to produce any but weak, lanky, pale-foliaged, and scanty-flowered plants in January in a house with rafters enough in strength to make three or four each, the panes no larger than the hand, the laps full of dirt, the paint overlapping the putty, admitting only a few faint rays of light, and the means of ventilation as antique as they are inadequate. Who has seen more "beautiful and fragrant" Hyacinths than we produce under glass, and by artificial means? The Dutch even are silent. Roses, too, are they sweeter, more beautiful in the open air than under glass? By artificial means we produce in our climate flowers (and unseasonably), that are the wonder of those who have a climate and soil peculiarly suited to their growth and perfection of bloom. This may not be general, but I believe it is, and would be more so were proper houses provided for forced plants, which are every year more in request for decorative purposes.

We want light, well-ventilated houses, no higher than sufficient to admit the plants and allow of these being placed a foot, or not more than 18 inches, from the glass; the houses to be roomy, so that the plants may be set at such distances apart that they will have light equally from all points, and with a sufficiency of piping, so that the heat given off would never in the most severe weather need to exceed 120°, better if less. There is no economy in a small amount of piping, for to heat water to a higher temperature the fire has to be made larger, and the draught greater, much of the heat passing up the chimney. No matter how strong the fire, the water can only be heated as it comes in contact with the heated surface of the boiler. And we want not only well-ventilated houses, but the air so warmed in entering that, by the time it reaches the plants, it shall be heated to a temperature little differing from that in which they are growing.

The best kind of houses are span-roofed, with a central bed chambered, or covered with flags, and holding about a foot of tan or plunging material for plants requiring bottom heat. There ought also to he a good, wide, stone or slate shelf round the house, and a pathway of from 2 feet 6 inches to 3 feet wide. Having 3-feet shelves along both sides, pathways 3 feet wide, and a bed 8 feet in width,

we have 20 feet, a good width, but not too wide. The glass on both sides should reach down to the shelves. A hundred-feet length of glass of this sort might be divided into three compartments—one to be kept at between 55° and 60° at night, and from 65° to 70° by day, with a rise of 10° from sun heat; the second to be kept 10° lower; and the third to be kept at from 40° to 45° at night, 5° higher by day, and 10° or 15° higher on fine days. A house of this description would be a great advance on the present system of spoiling the ordinary occupants of our greenhouses and hothouses by there maintaining the temperatures required for forcing plants. The plants are brought from a position much colder than that in which they are placed, they swell their buds, make weak growths, and form badly-flowered specimens. In all the three divisions I would have means of affording bottom heat, for it is quite as necessary in the cool house as in the warmer, to give newly-potted plants a start at the roots before they are excited at top. The means for giving bottom heat should be such that they could be worked separately from the system for top heat, or together, as might be necessary. The bottom heat in the cool house would be valuable for plants lifted from the open ground, potted, and at once placed in-doors for forcing; for by plunging the pots in the bed with a temperature 5° or 10° higher than that of the atmosphere new roots would speedily form, and we should have them better prepared to cater for the swelling buds; after a time these would push more strongly and more certainly. If the plants had been established in pots, and these were full of healthy roots, and therefore not needing bottom heat, it would be easy to set them on the plunging material instead of placing them in it.

The cool house would be sufficient for forcing every kind of hardy shrub or plant for three weeks. At the end of that time the plant could be placed in the next warmer division for another three weeks, and if wanted to bloom at once might be placed in the warmest house of all, where it would soon flower; but the second house would be sufficient forcing for many hardy plants. The hottest house would be very serviceable for bringing forward a class of plants that need a temperature intermediate between that of a stove and greenhouse, and for plants which, from requiring more moisture than the regular occupants of the stove, cannot well be bloomed there in winter.

The houses used for forcing could be employed for Vines in summer, which could be kept while at rest in covered boxes along the sides, or by using moveable sides, as described in "Sanders on the Vine." They might also be employed for Melons, Cucumbers, and a variety of other purposes.—G. Abbey.

SEEDLING ROSES.

We have had in "our Journal" two or three letters lately, complaining that the cultivation of seedling Roses has, to use the words of the writers, "got into a rut," by which the writers mean that our new seedlings exhibit no decided novelty, but are almost without exception repetitions, or at most but slight improvements, of long-existing varieties.

There are two questions arising from this fact, the truth of which we all allow. The first is, Is this more true of Roses than of any other flowers which have been long cultivated? Every florists' flower of which seedlings are raised by hundreds and thousands, must after a certain time arrive at a stage in which improvement is only possible in one of two ways; either by gradual degrees, the seedlings still retaining the impress of their parents—far the most usual mode;—or, more rarely, by the unexpected appearance of some new quality, or, at least, remarkable advance in perfection. The former is the case with ninety-nine out of a hundred of our novelties, whose novelty, indeed, is in most cases their only recommendation; in others, however, the advance is certain, though slight; and so it is that with Roses, as with other flowers, ten years or so will find us with flowers not much differing in class, yet much improved in those characters which we require.

With Roses, if I mistake not, the advance in this way has been more rapid than with other florists' flowers. I am not a grower of Dahlias or Auriculas, but the former do not seem to me very different at exhibitions from those I used to see in my long-past undergraduate days at Widnall's, of Cambridge, nor the latter from those that filled the shed in the garden opposite my old school; while this distance of time, nearer thirty than twenty years, has made an entire revolution in the character and quality of our Roses. And although we may be sometimes impatient when we see the new Roses of one year differing so little from those of the year before, and after growing our expensive acquisitions for a year or two, may indulge in a hearty growl when we consign the majority to the rubbish-heap; still, anyone who can compare his list at present with that of a few years past, will see that his collection has improved much, even though many of his recent acquisitions have by no means equalled the glowing description given of them in the lists whence they have been selected.

Occasionally, however, by no chance, yet in some way which we cannot comprehend, an absolutely new Rose is originated—a Rose which not only makes a sensation when introduced, but gives rise to a new race. Thus the Noisette Rose, which we call a chance seedling, has been the parent of all that class and of many of our Tea-scented, the Rose du Roi of our Hybrid Perpetuals, and so forth, the parent being not so much an improvement on the grandparent as a sport from it. And in our time we have seen this process at work, but, as might be expected, only at rare intervals. Some twenty-five years ago Géant des Batailles made its appearance among a host of dull-coloured Hybrid Perpetuals; then Général Jacqueminot was, perhaps, as great a stride; then Gloire de Dijon, and more recently, Maréchal Niel, each of these scarcely foreshadowed by previous flowers, and each destined to be the founder of a more or less extensive family. These are, however, necessarily few and far between, and in the intervals when we are waiting for them, what can the growers do but improve the families which we already possess? Here the grower of Roses has a great advantage over his fellows; he is not practically such a slave to fancy-points as others. Let a Dahlia have notched petals, a green eye, or an irregular outline, however fine it may be in other respects, no grower will keep it, were it even the long-desired "blue Dahlia" which we used to be promised in country newspapers in the days when I was young. But the most formal of all our fanciers keeps in his garden such Roses as Eugène Appert and Général Jacqueminot, deficient though they be in some one or other of those points on which he will insist as necessary. He abuses them, but he keeps them on, and admires them; and a Rose, though it may fall short of perfection in one or two points, yet if it be either new-high or new-delicately-coloured, and free to flower and open, will always have its admirers, and, more important to the raiser, its purchasers.

Still, if we are in a rut and wish to get out of it, the reason is simple enough, and a guess may be made at a remedy. Seedlings are raised in abundance from our best known and most prized Roses, and only those are retained which are absolutely good—at least, good enough to sell—while all the rest are destroyed, quite irrespectively of any special peculiarities which they may show, and no one, if I mistake not, ever thinks of retaining a Rose as a breeder which is not worth retention for sale; and so it is quite possible that plants which have shown a tendency to be the parents of yellow Hybrid Perpetuals, striped Teas, &c., have perished, because they were not good enough for sale, and no one cared to keep them to see what their seed would produce.

One of your contributors told us, among other matters, last autumn, that he had a quantity of seeds of Souvenir de Dr. Jamain. Here is a case in point. The Rose is third-rate—with me, at least, small and not full, but the colour quite a novelty, and were I inclined to foretell our next sensation, I should pitch upon a good seedling of Dr. Jamain as likely to cause it. This will be a step out of the rut.

But in the meantime let me ask our seedling growers whether it would not be worth their while to save as stock peculiar Roses, good or bad, for the chance of raising from them seedlings preserving their peculiarities, and surpassing them in quality.

We certainly want change—improvement we have, not very rapid, but still marked and evident. We cannot expect to have good novelties constantly, but more might be done if we were less contented to choose as parents of our seedlings Roses which have been parents of thousands of seedlings before.—Duckwing.

GOLDEN CHAMPION GRAPE.

There is a general complaint in this neighbourhood about the growth and progress of the above Vine, and if I may judge by my own experience of it, the complaints are not made without a just cause. Like myself, everyone complains of its weak growth and debilitated appearance, which are quite different from the description, or even from what the appearance of the

Grape itself would lead one to expect. I planted it in April last, in a newly-prepared border, along with more than twenty other Vines of different sorts, including Mrs. Pince's Black Muscat, Royal Ascot, and Madresfield Court. Most of these have carried their growth to the length of a 17-feet rafter, but the Golden Champion not only failed to start into growth at the same time as the others, but when it did start its growth was very weak, and the foliage very thin and bad in colour.

All the Vines in this house were allowed to grow as the season advanced, and owing to the weakness of the Golden Champion Vine I gave it more than its share of attention, but to my surprise it gradually became weaker until the point of its leader died off, and there it remains a miserable object, which to all appearance would be dear at a gift.

Now, if from my own experience I may conclude that many others in different parts of the country have failed to grow this Vine successfully under the usual treatment accorded to other Vines, I may fairly ask, What is the cause of this debility? also, What treatment are we to pursue in order to rear it up to the fruiting state, so anxiously sought for by everyone? In reply to the first question I shall venture to say it is more owing to the exhausting effects of a rapid propagation than anything else, for when a person considers the noble and attractive appearance of the fruit, together with the suitable parentage and likelihood of its becoming a desirable companion to the famous Black Hamburgh, it is not surprising that the demand for plants was enormous, and from the brisk propagation forced upon the raisers in consequence, the juices of the Vine were never thoroughly at rest before propagation commenced again, hence its weakness. In answer to the second question, I should say that no better plan could be advised than inarching on the Black Hamburgh, but I think all those who have their Vines already planted will do well to let them remain, but take care to thoroughly ripen the wood. I think Golden Champion will yet do well on its own roots, by making a good growth next year.—Thomas Record, *Hawkhurst*.

THE GLADIOLUS.—No. 2.

FONTAINEBLEAU.

I still linger about this classic spot—not, our readers may be sure, on account of the gilded salons of Diana de Poitiers, nor the charming glades of its wide forest, but on account of the interest I feel in the lovely autumn flower which has made this historic place dear to all who cultivate it; and I could not very well leave the mention of it without adding something as to the new varieties; and what more fitting time to write one's experience of those of this season as well as to indicate those yet to come? Before doing so, let me correct one or two errors which my unfortunate habit of scribbling has made me appear to make (I do not blame the printer, for I sometimes wonder how he does so well)—thus, I am made to say the Parisian "fairs," instead of Parisian firms; "pretty rough," instead of pretty enough; "*arrache*," instead of *arrachez*;" while by a *lapsus plumæ* I wrote "Molière instead of Ulysse.

There can be, I think, little doubt that the collection sent out by Monsieur Souchet last season comprised finer flowers and more of them than in the previous season, and, indeed, I make bold to say, than any former one; and as I have grown all the varieties named below under my own eye, have seen them with other growers, and compared notes, I rather fancy the judgment now given will prove tolerably correct.

Michel Ange.—I place this foremost, for it is a most remarkable flower. The description given of it in the catalogues led many to suppose that the spike would not be regular, but, as some one expressed it to me, all about the place. But this is not so. The spike is regularly formed, and the flowers are very remarkable, having more the appearance of a Lily than a Gladiolus, a peculiar dark crimson purple with white lines. In the bed it has a most effective appearance.

Homère, Thomas Methven, and *Madame Dombrain.*—I place these three together, for there is a great similarity between them. Of the three Thomas Methven is, I think, the best—a large, fine, and well-formed spike; the colour deep violet rose, flamed with carmine violet. Homère has more purple in it, the flaming, perhaps, not quite so brilliant; while Madame Dombrain has less rose colour. All these have the regular form of spike, and all are desirable flowers.

Schiller.—A curious shade of colour, having novelty to recommend it; it is called a sulphur yellow, and has the very faintest tinge of primrose. It bears some analogy to Anaïs, but is larger and finer in every respect.

Marie Stuart.—A very fine flower with long spike; the ground colour a very pale blush, flamed and striped with carmine cerise.

Argus.—A brilliant-looking flower, admirable for effect, but wanting in shape. The same may be said still more of

Romulus.—Dark crimson with large white spots, but the petals are pointed and irregular; still for its colour it may and will be grown.

Legouvé.—A magnificent flower, long spike. Individual flowers large and well shaped, fiery red colour; upper petals with a white line in them, large white spot on the lower ones. One of the best flowers of the year.

Madame Desportes.—A beautiful pure white, purer, I think, than La France or Norma of the year previous, with a very light violet stripe in the lower petals. Very fine.

Fénélon.—A very long spike. Very light rose colour with a violet tinge, but rather muddly.

Racine.—A long spike. Flowers, cerise tinted with violet. A well-formed spike.

Virgile.—A brilliant scarlet red flower. Long spike, well-formed flowers. A striking plant.

Circé.—A rose-coloured flower, largely tinted with lilac, and flamed with crimson, somewhat after Madame Furtado. Very pretty.

Corneille.—Well-formed spike. Clear cerise; the edges of the petals with deeper shade of the same colour.

I have not seen Antonius, Buffon, Isis, Jenny Lind, Montaigne, Picciola, or Van Dyck, but I do not think that they equal those I have named. Those who do not possess them will do well to procure Michel Ange, Homère, Thomas Methven, Madame Dombrain, Legouvé, Marie Stuart, Racine, Madame Desportes, Virgile, and Schiller.

With regard to the new varieties coming out this autumn, my notes on them were rapidly made. Madame Souchet was in despair; the baptism had taken so long that the dinner was behindhand, and yet here were two enthusiasts still poring over them, and then, surrounded as they were by other flowers, what wonder that one's head almost got off its balance. I believe, however, that the following is a tolerably correct *résumé*. There are twenty-four to be brought out, divided into four separate classes, varying, of course, in price.

In the first class are Phœnix, a fine cerise colour; Roseta, very beautiful white with cerise blotches; Petrarch; La Candeur, a fine white; Robert Fortune, with deep spot; and Orphée.

In the second class, Elizabeth, bright pink; La Sylphide, white with large blotch; Perfection, white with deep flame; Mariana, very large pink; Agathée; and De Humboldt.

In the third class, Spectabilis, fine colour; Adanson, something in the style of Anaïs; Bossin; Asmodée, excellent spike of deep scarlet; Delicatus; and Rosea perfecta.

In the fourth class, Welpers, Eleanora, Sultan, Gloria Florum, large white; and Dr. Livingstone, very bright, but not very large.

It is clear that we must be gradually thinning out our older varieties when newer kinds of the same style are so far superior, and yet we do not like to give them up. It has been feared by some that we were losing vigour in these new kinds and gaining beauty at the expense of constitution, but I hardly think so. Some of the older kinds—Napoléon III., Achille, and James Veitch, for example—are far more delicate than Norma, La France, or Meyerbeer. Some of the new kinds are undoubtedly so, Semiramis for example, but they are outnumbered by the more vigorous sorts. M. Souchet has clearly understood, that it is better to give short than long names to things; we have no "Souvenir de Madame la Comtesse de ——," and such-like absurdities, as in the Roses.

I have not ventured upon giving any selection of the older varieties, as I have done so before, but have merely referred to the newer sorts, and in my next shall have something to say of the difficulties that beset the cultivation of this fine autumnal flower.—D., *Deal*.

Hurricane in Jersey.—From early in the evening of Saturday, September 11th, to Sunday morning, Jersey was visited by such a hurricane as has not been known there, so say the inhabitants, for more than thirty years. Thriving, blooming gardens are left like wildernesses, and plentiful crops of Pears, without any exception that I have heard of, have positively been cleared and scattered on the ground; nor have the Apples fared better. By Sunday morning the Tomatoes and plants

of that kind had the same appearance as they would have worn in England, after a very severe night frost. The plants were lying along the ground, the leaves black, shrivelled, limp, and withered We are about 300 yards from the sea, and from a gully of the garden which receives the wind in its force, some Apples which were tasted had a strong flavour of salt. Flowers, of course, for the present, are done for; the vegetable crops are injured, and the trees much shaken in the earth. The wind was, I believe, S.W., and the barometer went down and up with wonderful variations throughout the night.—E. W., *Jersey*.

FRUIT-TREE STOCKS, PARTICULARLY THE QUINCE.

At page 200 of The Journal of Horticulture, Mr. Rivers seems to be pleased with the opportunity I have given him of "ventilating" the above subject. He thinks I have laboured under a mistake for many years about the Portugal and Angers Quinces. I must say that the supposition is gratuitous on his part, and that I think myself at least his equal on the subject. He further says it is probable that I have neither the one nor the other true to name. Why should I not have them as well as himself? I think he pays my intelligence a bad compliment. Mr. Rivers refers to his having obtained his knowledge of the Quince stock from the "Catalogue" of the Horticultural Society, compiled by Mr. Thompson about 1831. Mr. Thompson's knowledge of this stock could not then have been very great, as he had been only in the gardens about six or seven years. But what Mr. Thompson recommended in the first edition of the "Catalogue" I do not know, but he has made no reference in the edition of 1842 beyond the remark that the Portugal Quince "is the best sort for grafting Pears upon," and this is my opinion also. Merlet, who wrote three hundred years ago, says upon the choice of Quince stocks for grafting, "that the Portugal is the best and most favourable of all for grafting our good Pears upon; that the rise of the sap is so strong therein, that it produces large and excellent fruit of a beauty and bounty extraordinary; besides that the graft does not make a swelling at its junction with the stock, this latter being so strong that it has complete mastery of the subject grafted upon it." Now, this is just what I find. Mr. Rivers likes the Angers Quince because it is easily propagated, as is also the sort called Doué, but a facility of propagation does not always constitute a stock's being the best. However, I have no more difficulty in propagating thousands of the Portugal Quince than I have of the others, but my system of doing so is quite different from that pursued by Mr. Rivers—*i.e.*, layering, by cuttings, or by grafting.

Mr. Rivers has a little hit at our Somerset climate—whereas our Somerset climate is just the sort to produce fine healthy trees with well-ripened wood that will withstand most winters—that is, if the trees were originally from a country where frosts prevail, not such as Candia or ancient Crete, the birthplace of the sort of Quince from which all those we use as stocks have sprung, more especially the Angers and Doué varieties. Mr. Rivers obtained from M. Leroy one of each kind of Quince, as mentioned by himself in an article written not very long ago, if my memory is right; and from this same source I obtained not only all the sorts of Quinces that Mr. Rivers did, but I also had from M. Leroy fruits of above twenty other kinds, out of which I extracted the seeds, and from these raised several hundreds of plants, many of which bid fair to be rivals of the veritable Angers. In fact, I think I am pretty well up in the subject of Quinces. When I commenced I intended to have gone into the subject botanically, but I have not done so, and I daresay the Editors are as well pleased.

I now come to the Pear Nain Vert, and will quote a passage from M. Leroy, the accomplished and learned author of the "Dictionnaire de Pomologie," a work at once a marvel of research, learning, and cheapness. He says, "I will add, having grafted upon this little fat tree (*egrasseau*), the Belle Angevine, which is now eight years old, has remained dwarf, and produced enormous Pears." So much for the "*château en Espagne*." We shall see some day, if we all live.

Mr. Rivers, however, in the same paragraph broaches a subject, although not differing much from the Nain Vert one, dismissed with a supposition that I think is not borne out by any physiological reasoning that I am acquainted with—viz., the disruption of the vessels of the stock to meet the requirements of the graft. This supposition is in my opinion a bigger "*château*" than the possibility of obtaining enough of seeds from the Nain Vert Pear for commercial purposes. Let only a demand arise, and we shall see.

I now come to a bewildering paragraph—why fifteen sorts of Paradise stocks? I do not think I shall try to procure so many Paradise stocks as fifteen, being perfectly contented to think that I have already the best stock of this kind in existence. Mr. Rivers has obtained it in a roundabout way, and is forced to give it at least no secondary place. Mr. Rivers, in commenting upon what I wrote about the sale of Pear trees for double-grafting, tries to shove them overboard by saying that those I mentioned were of all kinds of refuse, and not worth packing and carriage, and further hints that the person who sells them got his knowledge from him. Now I know the party alluded to, but did not know that he sold such rubbish. The parties I deal with graft special kinds for the purpose, as Mr. Rivers does Beurré d'Amanlis.

I now come to the last portion of this knotty subject, the working of Apricots upon Apricots, &c. As far as my own experience goes, it is this: Having several times imported Apricot stones and raised thousands of them, I had a good opportunity of trying how the best sorts would do upon them. My success was very, very indifferent. Most of the stocks proved so tender that it was difficult to keep enough alive to experiment with. Those which I was enabled to work produced such weak wiry shoots that there seemed but little hope of ever obtaining fruit from them; those that were budded and came to a bearing state, produced fruit either hard and close-fleshed, or so watery and sour that they were perfectly uneatable. Added to this, the very kernels partook of their austerity, and even under the most favourable conditions the fruit remained unripe, and in all cases the flesh was adherent to the stones. It seems, therefore, from my experiences that the stock exercises a great influence upon the quality of the fruit, more especially in certain seasons, and that the graft but rarely, or very little, influences the stock. The subject of stock culture is, therefore, one fraught with great interest, and deserves the utmost attention. That it will receive that attention from some there is no doubt; but I am afraid that the generality of cultivators are indifferent to the benefits that would accrue from a careful study of the subject. It is now just half a century since I commenced the study of horticulture, and I have spent that time in ardent research in all branches connected with it, and with Mr. Rivers I may say that "my life has been, and still is, a life of research and experiment;" and although the allotted threescore years and ten are in my case, as in Mr. Rivers's, fast filling up, yet I can say my love of Flora and Pomona knows no abatement.

There is one portion of Mr. Rivers's article which I have not touched upon—that is, where he speaks of sending me some of his Apple trees. I believe some trees did arrive here, but being without names were consigned to the faggot-heap. As to answering his note, this I did not do for reasons I need not mention here.—John Scott.

VIOLA CORNUTA PERFECTION.

I saw this superb seedling Pansy at Rotherfield about a fortnight ago, and regret that I could not attend the meeting of the Royal Horticultural Society's Floral Committee, on the 7th inst., to record what an opinion I had formed of its superiority over all other Violas in respect to its profusion of bloom and rich colour, which is as much like that of Achimenes Mauve Queen as it is possible to be. Mr. Scott, the gardener, first pointed it out surrounding one or two beds in the flower garden, which is in one of the driest spots that could be well conceived, being on the top of a hill, and having a light sandy soil resting on a gravelly base. I then said, "Very beautiful!" but on his pointing out a bed, 11 feet by 4 feet, immediately under a west wall in the kitchen garden, exposed to the full blaze of this extraordinary summer's sun, such a display of bloom and healthy foliage (which partakes more of the character of the ordinary Pansy, V. tricolor, than that of V. cornuta), met my eye, that I could not help exclaiming, that it was the finest thing I had met with this season; and to such a man as a Gibson or a Bennett it will prove invaluable.—James Cutbush.

PROPAGATING POTATOES FROM EYES.

I planted in March last, 1 lb. of Early Rose Potato in the garden of the Provost of King's College, Cambridge, and when I took them up, August 30th, there were no less than 142 lbs.

They are a very fine sample, and when cooked they are white and floury. I treated them in the following manner :—I had five Potatoes of equal size, I put them in the vinery and started the eyes. I then cut them into sixty-two sets, and gave the ground a coating of manure from the Melon pit, 2 inches thick. I placed the sets 4 inches deep, and 16 inches by 30 inches apart.—N. CASTLE, *Gardener*.

[Any other Potato would have done the same.—EDS.]

HOUSE FOR ROSES.

I HAVE had erected a Rose house in which the Roses are planted in beds and borders. The novelties are—1st, The height of the sides, thereby allowing space for rampant climbers, such as Maréchal Niel, Isabella Gray, Cloth of Gold, Solfaterre, &c.; and 2nd (which is most important, and, I think, an entirely new idea), that the side lights open on a level with the ground inside the house, so that the air circulates well round the plants.

Most Rose houses are built with a wall 3 or 4 feet high, and then the glasswork is placed upon the wall, so that one of the first principles of Rose-growing is violated by the plant being, so to speak, in a hole. In cultivating Roses out of doors one is continually stirring the soil round the roots in order to let in the air. Now, what I wish to show is, that if a Rose house is built in the ordinary manner, it is quite impossible that the air can reach the roots and circulate round the lower part of the plants, as it should; and, keep the soil stirred as one will, there will always be a state of semi-stagnation highly productive of mildew and other evils.

To amateurs far enough advanced in Rose-growing to have a Rose house built, I need not point out the benefit of syringing often, and the advantage of having a liquid-manure well not far off; it is also good to have a butt at one end of the house to lead the gutter-pipe into, so as to insure a supply of rain water. This house is 32 feet long, 18 feet wide, 12 feet high in the centre, and the height of the sides is 7½ feet. It is built on a brick foundation, and is made to take to pieces. It is lined with wirework, so that the climbing Roses are independent of the woodwork.

I annex a list of Tea Roses grown in the above house which may be useful to some of your readers, with a few remarks on the newer or more uncommon sorts.

Céline Forestier
Cloth of Gold
Isabella Gray
Lamarque, elegant, not full enough.
Maréchal Niel
Narciase
Solfaterre, fine grower
Triomphe de Rennes
America, first-rate at times, but not to be depended on
Adam
Alba rosea
Archimède, good
Bouton d'Or, pretty button-hole flower
Bougère, first-rate
Climbing Devoniensis, too much wood in proportion to the flowers
Comte de Paris, very good, rather variable
Devoniensis
Duc de Magenta, good
Elise Sauvage, very elegant
Goubault
Homer
Jean Pernet, middling
La Boule d'Or, fine under glass
L'Enfant Trouvé
Louise de Savoie, good under glass, will not open here out of doors
Madame Bravy
Madame Falcot
Madame Margottin, very fine
Madame Willermoz
M. Furtado, a fine yellow Rose
Niphetos
President
Rubens
Reine de Portugal, bright orange, a first-rate new Rose, slow opener, wants growing under glass
Sombreuil
Souvenir d'Elise
Souvenir d' un Ami
Vicomtesse de Cazes

—G. H. M.

QUACKERY AMONGST THE GARDENERS.

THE pursuit of horticulture is generally thought to have a good effect on the mind. The striving after truth, the effort at perfection, must ennoble. The gardener who loves his art has no idea of keeping as a secret any improvement he has discovered in culture. The readiness, nay, the anxiety, of our first-class gardeners to impart knowledge is well known; the pages of "our Journal," and similar publications, bear evidence of this. If a gardener professes to have secrets he is unwilling to impart, most persons set him down at once as a fool.

Nor is this willingness to impart information unknown amongst nurserymen, and there are few of whom I should hesitate to ask a question, either concerning culture or propagation. There may be a few ignorant men who, with low cunning, will seek by any means to derive information, and impart none in return—to enter their neighbour's propagating house, for instance, whilst carefully locking the doors of their own; but I am glad to say a more liberal spirit is now the rule. The first-class horticulturist has the feeling of a first-class medical man, that knowledge ought to be disseminated for the public good, and that it is as mean to withhold information as it is foolish not to desire it. In spite of this increasing liberal feeling, there are still symptoms of a quackish spirit abroad. What is it but quackery, when nostrums are advertised at unheard-of prices? One can imagine a man unconnected with horticulture advertising something for the benefit of gardeners, and if it proves good and worth the money charged, gardeners will use it till they discover something equally efficacious. But for a man, whether gardener or nurseryman, to advertise anything, a manure, for instance, at double or treble the price it can possibly be worth, and to try to make people believe his success as a cultivator is due to its use, is, in my opinion, rank quackery.

I have at the present time plants of Golden Champion and Madresfield Court Vines, about 20 feet long, and as thick as many walking sticks; these have had good soil, plenty of heat, and a little sheep-manure water, with plenty of attention, which are all that Vines require, and I do not think any patent manure would improve them. No doubt, competition in business is great, and the profits of business small, but let us choose rather the respect which follows professional conduct, if associated with small profits, to the larger gains which sometimes reward quackery.—J. R. PEARSON, *Chilwell*.

BOUQUETS AT THE MANCHESTER SHOW.

MY attention has been called to some remarks of Mr. W. H. Turner respecting bouquets at the Manchester Exhibition, in which he charges me with neglecting to place cards upon those shown by me. Were it necessary, myself and four others are prepared to state on oath that the Society's cards were placed upon the vases holding the bouquets, and were there up to the time the tent was cleared. When the judges came round the cards had been abstracted, and the judges supposed the bouquets were not for competition. Possibly some of the baffled competitors may know something of the matter.—RICHD. S. YATES, *Sale, Cheshire*.

WHO IS TO BLAME?

A QUESTION certainly not answered by Messrs. Carter & Co., who, I learn for the first time, are, in conjunction with Messrs. Hurst & Son, the fosterfathers of Laxton's Supreme Pea. If Messrs. Carter will re-read my notice of it, they will see that they have not the least reason for saying that I pit my judgment of the *general* character of that much-exalted Pea against their own or anyone else's, I simply state a few facts (mighty ugly ones, too, against the popularity of the said Pea), with reference to its growth with me, and the manner in which it has belied its character. I bought a sealed packet, and I repeat that it in no way resembled its picture and description, save in the least important particular—the shape of its pods. Remembering what the astute Horace says, that "*pictoribus* atque poetis" a certain (very uncertain) license is given, I would not have complained of anything so trivial as the number of Peas per pod, but when one of the main points of excellence for certain purposes is entirely mis-stated—viz., dwarf habit, there is something to complain of. Nor would I have been too particular here; had it been 50 per cent. taller than advertised, and in other respects true to its description, I would have remained silent; but when it exceeds by 100 per cent., being 7½ feet high), I am very slow to believe its average height is 3½ feet; and I shall be glad to know whether anyone has found Laxton's Supreme true to its character, especially in this particular.

Messrs. Carter's remark that, "as regards the price of an article, it is worth just what it will fetch," is at once both true and false; it is the answer which the "cheap Jack" made to the countryman who purchased the historical razors, "made to sell." True in a sense in which Messrs. Carter would be the last to accept it, it is false in this, that an article not worth 6*d*. would, backed by Messrs. Carter's name, sell readily for 3*s*. 6*d*.; but, then, they would sell not the article only, but so much of their own reputation. Confidence in the integrity of such firms as Messrs. Carter & Co. induces growers to give any price asked for such novelties as they may desire; nor can they in reason complain of the price, *if they get what the catalogue says they pay for*. In the present instance I certainly have

not, and I ask, Who is to blame? As to the retail price—3*s.* 6*d.* per half pint—let anyone who doubts its being high, search through his old catalogues till he find its like.

As to enterprising seedsmen giving £100 per bushel for stock seed, it matters not to the grower whether they give £100 or 100 pence; he regards what they promise, what he pays, and, most of all, what he gets. Unquestionably such firms as Messrs. Carter & Co., *cum multis aliis*, have done great things in the cause of horticulture, and every grower must wish them well; but their prices for stock seed is their affair, not the grower's, being purely a trade speculation, founded on their own experience and acumen.

As to my "looking at Peas in my neighbour's garden instead of my own," I can only wish that I had had such luck in the case of Laxton's Supreme. From all I know of it at present, I am inclined to adopt Messrs. Carter's hint with regard to the other first-class Peas of Mr. Laxton which they intend offering to the public—viz., to look at them in my neighbour's garden before I introduce them to my own, though no one is more willing to pay such a price as will remunerate the labours of crossing, selection, &c., whereby our fruits and vegetables are improved, than—C. C. E.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 21ST.

FRUIT COMMITTEE.—George F. Wilson, Esq., F.R.S., in the chair. A prize was offered by H. G. Bohn, Esq., for a dish of Peaches grown on standards in the open air, but there were no competitors. Mr. William Paul, of Waltham Cross, sent four sorts of seedling Grapes merely for exhibition, Mr. Paul desiring only the opinion of the Committee as to those varieties which it would be desirable to cultivate. Nos. 2, 4, 10, and 15 were selected by the Committee, and Mr. Paul promised to exhibit them again at next meeting, when there would be a collection brought from the garden at Chiswick. No. 10 is a very fine Frontignan; No. 2 a large-bunched variety with a rich Muscadine flavour, as also is No. 15. Mr. Ross, of Welford Park, Newbury, sent a seedling Plum which did not possess sufficient merit to warrant a certificate.

G. F. Wilson, Esq., brought a dish of very handsome fruit of Transparent Gage Plums. Mr. Wilson also brought a quantity of nuts in clusters as taken from the trees, all of which were pierced with large holes and the kernels abstracted. This was produced by the attacks of field mice, which climb up the branches and attack the fruit. Several of the members have observed these mice attacking the Filbert and nut plantations. An erroneous impression is abroad that these attacks are due to the Coal Tit (Parus ater), the beak of which could not possibly have caused the effects produced.

Messrs. Bunyard & Son, Maidstone, sent fruit of a seedling Apple, which was so small and so much decayed that they were requested to send it again another season. The Rev. George Kemp, of Sevenoaks, brought fruit of Rivers's Summer Beurré d'Aremberg, of excellent flavour, though small on account of the season.

Mr. Gilbert, gardener to the Marquis of Exeter at Burghley, sent fruit of Duke of Cornwall Melon, a very large fruit, weighing 8¼ lbs. It has a clear yellow, smooth skin and a very thick green flesh, and was scarcely ripe, but it had all the properties of a first-rate fruit. He also sent a seedling raised between the Duke of Cornwall and the Victory of Bath. It is a white-skinned variety with a thick green flesh, and very richly flavoured. It was awarded a first-class certificate, and named Burghley Green-flesh. Mr. Goldsmith, gardener, Polesden Lacy, Dorking, sent fruit of the old Windsor Prize, a scarlet-fleshed variety of good flavour. Mr. Stacey, the Gardens, South Bank, Edgbaston, Birmingham, sent a seedling Melon, which also proved to be the Windsor Prize.

Mr. Fairbairn, gardener to W. Death, Esq., Bishop Stortford, sent a good specimen of the Blood Pine, weighing 6 lbs. 9 ozs., to which a special certificate was awarded for meritorious cultivation. Mr. George, of Putney Heath, sent a Strawberry plant in a pot bearing fruit on a runner of the current season. Mr. John Haisman, gardener to Horace Martin, Esq., Oldbury Place, Ightham, sent very good specimens of Forbidden Fruit.

Mr. Fenn, of the Rectory, Woodstock, brought specimens of Ribston Pippin grown on trees grafted on the Blenheim Pippin, exhibiting very remarkable results as to the influence of the stock on the graft. An account of this interesting subject will be found in our next number. Mr. Fenn also exhibited three kinds of home-made wines, one from the Espiran, another from the Royal Muscadine, and a third from Muscat of Alexandria, all grown in the open air. All of them were very well manufactured wines, and the result of a persevering course of experiments which Mr. Fenn has been carrying on for a great number of years to ascertain the practicability of producing in this country a cheap and wholesome wine from home-grown Grapes. Mr. Fenn's efforts have at last been crowned with great success. The first sample, which is red, was a very good light wine, with a good deal of body and flavour, and far superior to many of the *vins du pays* one gets in France and Switzerland. The second was quite a first-rate wine, somewhat of the character of a white Burgundy, and this received a first-class certificate. The third was a light sparkling wine very pleasant to drink, but thin, and would not keep long; nevertheless a great advance on home-made sparkling wines generally.

Mr. Fenn also sent two varieties of seedling Potatoes—one, named The Rector of Woodstock, a fine-flavoured and very prolific Potato, which was awarded a first-class certificate. The other was not considered of sufficient merit, it being without much flavour, though very floury, and a fine-looking Potato. Besides these, Mr. Fenn had a collection of what he considered the twelve best sorts of Potatoes, for which he received a special certificate. From Messrs. Barr & Sugden, King Street, Covent Garden, came a very large and interesting collection of Onions, for which a special certificate was awarded.

FLORAL COMMITTEE.—Rev. J. Dix in the chair. W. Lacey, Esq., Southampton, sent a seedling bronze Zonal Pelargonium. From Mr. Warren, Salisbury, came some very neat plants of a dwarf small-flowering Veronica, named Blue Gem. This is one of the prettiest plants that have been exhibited this year; its dwarf, neat habit will make it very useful for bedding and decorative purposes. Mr. Warren also brought a plant of Viola Perfection, and flowers of the same were sent by Mr. Dobson, of Alton Park, to a previous meeting. A first-class certificate was awarded it as a valuable bedding variety. Mr. E. Bland, Richmond Hill, sent four seedling hybrid Nosegay Pelargoniums and others, but of no special merit. Symmetry, a well-formed scarlet flower, was good, but not equal to some others.

A collection of Orchids from the Society's gardens was awarded a special certificate. Among them a Cypripedium Reichenbachii, a new plant of no particular beauty, which is reported to produce from twenty to forty flowers on each spike, was awarded a first-class certificate.

Mr. Wimsett, Chelsea, sent his two hybrid Ivy-leaved Pelargoniums—viz., Willsii rosea, dark bright rose, which had received a first-class certificate, also Willsii, a lighter and paler rose, to which a first-class certificate was awarded. These are very beautiful plants, and will, doubtless, be in great request. Mr. Whitehorn, Southampton, sent seedling Zonal Pelargoniums Queen of the South, Delicatum, and Jolly Captain. Mr. Cuthbush, Highgate, exhibited two very well grown specimens of Cockscomb, which were awarded a special certificate for good cultivation. Mr. Nash sent flowers of two seedling Pansies, also cut trusses of Zonal Pelargoniums; the latter without petals, the Pansies of no merit, of the usual character found among any batch of seedlings. Mr. Cannell sent seedling Zonal Pelargonium Mrs. Cannell, pale pink, of moderate form; also Yellow May, golden-leaved.

Dr. H. Rogers, East Grinstead, sent an Epidendrum to be named, and Cattleya Harrisoniæ. From Messrs. Bell & Thorpe came a collection of cut Petunias, many of them very pretty, also double Zonal Pelargonium Miss Evelyn. This being the seedling plant, was not eligible for a certificate; it is very promising, the flower of a bright rose colour. Messrs. Salter sent a very good collection of succulent plants, for which a special certificate was given; also Centaurea hybrida, a seedling of great merit with fine broad foliage. A first-class certificate was awarded it. Mr. Cripps, Tunbridge Wells, sent Hydrangea paniculata grandiflora, a very ornamental, hardy, Japanese plant, producing large erect spikes of white flowers. A first-class certificate was awarded it. Mr. Cripps likewise exhibited Cedrus verticillata glauca, a glaucous variety of Deodar. From Mr. G. Smith, nurseryman, Hornsey Road, came Zonal Pelargonium Formosa, a fine shaded salmon flower.

Mr. Green, gardener to W. W. Saunders, Esq., brought a new form of Agave, Agave pectinata—a first-class certificate was given. Messrs. Lee had plants of Cupressus alba-spica; there was some doubt expressed as to its correct name. A first-class certificate was awarded, and it was requested that it should be sent again. Messrs. Lee also exhibited Thuja Tom Thumb, a diminutive plant, fit for a glass case or window; a collection of Centaureas, not sufficiently distinct from others, and Alternanthera magnifica, a free-growing variety. Mr. George, Putney Heath, brought several Zonal Pelargoniums, some of them being seedling plants, which by one of the Society's rules cannot receive certificates; also a collection of cut flowers of seedling Zonal Pelargoniums, among which were two of considerable merit, these being Mrs. Cannell, a fine, bold, white flower, the centre striped with pink, and King of the Roses, a very promising flower.

Mr. Wheeler, Warminster, exhibited a seedling Dahlia, Lord Weymouth, a bright yellow, the petals deeply margined with dark red; the flower is, perhaps, too coarse for the florist's eye, but as a decorative flower for the border it is very useful; a second-class certificate was awarded it. Mr. C. Turner received a second-class certificate for seedling Dahlia Alice Gair, a first-class certificate for Provost, and a special certificate for a very fine collection of cut flowers. Mr. Burgess, Chelsea, sent seedling Dahlias Cottage Girl and Mrs. Burgess. Mr. Rawlings had seedling Dahlia Royalty, the finest seedling exhibited, of excellent form, and bright yellow colour; a first-class certificate was awarded it. Mr. C. Parker, Winkfield, sent two seedling Dahlias. Mr. Cox, gardener to W. Wells, Esq., brought an interesting collection of cut specimens of Conifers with fine cones on them, some of them having been rarely known to produce cones in this country. A special certificate was awarded the collection.

GENERAL MEETING.—J. Russell Reeves, Esq., F.R.S., in the chair. The election of one new Fellow was followed by the usual announcement of awards, and the Rev. Joshua Dix took the opportunity to

mention in feeling terms the loss which the Society had sustained in Mr. Veitch, of Chelsea, and Mr. Robert Thompson.

The Rev. M. J. Berkeley then pointed out to the meeting the fine specimens of Pine cones from Mr. Cox, of Redleaf, particularly Pinus Smithiana, commonly known as Pinus Morinda, and the species under the name of Picea cephalonica, which, however, he believed not to be true to name, Picea cephalonica being rather tender. The fruiting of these Conifers he believed to be in some measure owing to the wood being so well ripened last year. A Fungus found in a sewer was next noticed as being probably a singular form of Agaricus ostreatus; and in connection with this it was mentioned that the exhibition of edible and poisonous Fungi is fixed for the next meeting.

Mr. Berkeley having adverted to Mr. Fenn's exhibition of Potatoes, consisting of two series, in which Hogg's Coldstream and Shutford Seedling, and Early Emperor and Fenn's Onwards, were respectively the male and female parents, mentioned that some of the progeny had actually degenerated so much as to resemble the wild Potato. He then read the following paper by Mr. Fenn on the results of grafting Potatoes:—

I grafted this year Red Ashleaf on Dickson's Premier, Paterson's Scotch Blue on Royal Albert, and *vice versâ*. I have been unfortunate this season in regard to the "taking" of the grafts. I planted and kept the grafted sets in 6-inch pots, contrary to my later practice of planting them in the open ground when the shoots in the pots have pushed 5 or 6 inches out of the soil. This may have tended to cause non-success as regards the cicatrisation of the skins; nevertheless, sufficient results have been arrived at to afford conclusive evidence as to the possibility of grafting one Potato with the eye of another.

On July 14th, I examined two sets, an eye of Royal Albert (a handsome, round, white Potato), grafted on Paterson's Scotch Blue. The eye had held perfectly fast to the tuber, thereby giving hope of some influence being exerted between the stock and the graft. I made the graft fit as perfectly as possible into the wedge-like, sliced-out cavity in the tuber, but at the above date the graft had swelled-out of its first position, though not sufficiently to disunite itself from the cicatrix of its own skin and that of the stock on one side. I gave several good tugs at the graft, but I could not displace it, and I sent it to Dr. Masters to verify this result. Dr. Masters wrote me in answer, "In one case the cohesion was evident, but I do not see that the new tuber or the haulm is at all affected by the grafting process. We must have more conclusive evidence than that. I see the union is not merely along the rinds, but in the cellular mass of the Potato as well. I have forwarded the tubers to Chiswick. The whole subject is very interesting."

The other sort sent to Dr. Masters was the eye of a Paterson's Scotch Blue on Royal Albert, no cicatrix, or union of the skins, had formed, but some of the young tubers were half-coloured, others less coloured, and one was perfectly white, none of them showing blue all over like the sort. I asked Dr. Masters to forward them to Mr. Barron, and request him to plant them and note whether the colouring was permanent.

Now for "more conclusive evidence." I wrote on the 14th of July that I durst not then meddle with the roots of my last year's grafted Potatoes. Their appearance I noted thus:—Fenn's Onwards on Almond's Yorkshire Hero: an Onwards haulm, but earlier, and very diminutive in comparison. Hero on Onwards: I can perceive no difference in the haulm as compared with those not grafted, except, perhaps, that the foliage of the grafted sets is of a more glazed green. Yorkshire Hero on Fluke: haulm looking like that of the true Yorkshire Hero, with not a symptom of the dark green tinge of the Fluke foliage. Milky White on Yorkshire Hero: haulm like that of a diminutive Milky White, quite ripening off, whilst its namesake by its side was in full vigour of leaf. Milky White grafted on Fluke (this I did by mistake; I intended to have grafted the Milky White on itself, to try what would be the effect, if any): haulm showing quite a different character from that of Milky White, being not so branching, and of a darker, more upright, and more robust habit. All the above examples in 1868 united at their rinds more or less completely soon after they were planted out—a fact which I proved by inspection.

I planted the above-named Potatoes on April 15th, when the graft of Onwards on Hero showed sprouts decidedly greener than those of the true Onwards; and when I dug them up, on August 9th, their haulm was not nearly so ripe as that of the latter, and their produce generally, for form, proved rounder than Onwards. The Milky White grafted on the Fluke is the only other decided "conclusive evidence," and that is conclusive enough in the wrong direction; the character, as well as the Potato, being quite spoilt. In short, I may have gained (but I must wait another year to prove it), an improvement by grafting the Onwards on Yorkshire Hero, and that I fear will prove at the most but a mere pennyworth of Potato to a sack of trouble, though I shall be well content if, by the experiment, I have added my mite to the science of horticulture.

The subject, Mr. Berkeley said, was one of great importance, and Mr. Fenn's paper very suggestive.

Mr. Murray drew attention to a collection of Cacti from Mr. Wickham, who was travelling on the banks of the Orinoco, and moved a vote of thanks to the exhibitor, and this having been passed, the proceedings closed by the Chairman announcing the next meeting would be held on October 5th, when there would be an exhibition of Grapes as well as that of Fungi previously referred to.

SALT FOR STRAWBERRIES.

The quantity of salt used by me for the Strawberry plants (see page 213), was the contents of a herring barrel—that is, the brine that a barrel of herrings contained, and I spread it between two rows of about sixteen plants on each side, thirty-two plants altogether. You will see, therefore, it was a good pickling, and to all appearance yet the plants are much benefited by it, being the most healthy of any. There has been a mistake with the Potato ripening in two months from planting; it ought to have been two months after coming through the ground.—W. T.

[The benefit to the Strawberries must not be altogether ascribed to the salt in this instance, for the oil and other refuse from the herrings are powerful fertilisers.—Eds.]

EXPERIMENTS WITH POTATOES.

We give below the results of experiments with fourteen varieties of seed Potatoes conducted under the direction of Admiral Hornby. All the varieties are treated alike, and sown in black soil on the Knowsley Cottage Farm. Nos. 1, 2, 3, 5, 6, 8, 9, 13, and 14, were obtained from Scotland. All these are good eating Potatoes, the first particularly so; and of this kind beautifully shaped single Potatoes have been turned up from 28 to 31 ozs. in weight.

No.	Weight of Seed sown.	Names of Potatoes.	Weight of Marketable Produce.
1.	14 lbs. ..	Paterson's Blue	618 lbs., or 44 times weight sown.
2.	14 lbs. ..	Paterson's Regent.....	539 lbs., or 38 times.
3.	14 lbs. ..	Paterson's Red	401 lbs., or 28¾ times.
4.	14 lbs. ..	Daintree's Early	394 lbs., or 28 times.
5.	14 lbs. ..	Paterson's Oval Blue ..	359 lbs., or 25 times.
6.	14 lbs. ..	Paterson's Victoria	329 lbs., or 23½ times.
7.	14 lbs. ..	Webb's Imperial	272 lbs., or 19 times.
8.	14 lbs ..	Paterson's Napoleon ..	229 lbs., or 16 times.
9.	14 lbs. ..	Dalmahoy	221 lbs., nearly 16 times.
12.	14 lbs. ..	Pinkeye Kemp	200 lbs., over 14 times.
11.	14 lbs. ..	Arrowsmith's Seedling	179 lbs., or 13 times.
12.	14 lbs. ..	Fluke.....	95 lbs., or 7 times.
13.	14 lbs. ..	Bloomer	92 lbs., or 6½ times.
14.	8 lbs. ..	Rosse's Early.....	272 lbs., or 34 times.

—(*The Gardener.*)

GARDENS IN EAST KENT—NEWLANDS.

Newlands, the residence of James Lake, Esq., is near the direct road from Faversham to Sittingbourne, and about three miles from Faversham. The surrounding country presents no striking feature, no view on which the eye "loves to linger;" the only prospect of any considerable extent being across the low, flat marshes of Teynham, over the dreamy Swale, famous for its oyster beds, with the Isle of Sheppy in the distance. The soil of the neighbourhood is generally a deep rich loam, but it varies very much, and would form an interesting study for the geologist; in a radius of a few miles may be found deep beds of clay or brick earth next to equal depths of a smooth kind of sand containing very little gritty matter; then may be seen beds of gravel of irregular depths, and then, as at Newlands, solid beds of chalk of immense thickness.

Passing from the entrance along the carriage drive, bordered with shrubs, the mansion, a modern building of moderate dimensions, is before us. At the extremity of this drive, on the right, advantage has been taken of a vacancy in the shrubs, caused, probably, by the proximity and shade of many lofty deciduous trees, to form an ornamental fernery, which struck me as being in very good taste. It consists principally of a prettily-constructed archway leading to a winding path which is lost among the trees; the vacant space on each side of the archway is occupied by irregular masses of brick burrs, of which material the arch is also formed. The burrs are a number of bricks, which, having run together in the kiln, are useless for building purposes; they are slate-coloured or bluish grey, a fine neutral tint, harmonising well with the sombre hue of the dark foliage of the surrounding trees. Many choice Ferns were flourishing among the burrs. I particularly noticed a handsome specimen of Lastrea Filix-mas cristata angustata.

A door close to the fernery opens into a back yard, on the opposite side of which is the principal kitchen garden, enclosed by walls and glass houses. Turning to the right from the entrance we at once come to the orchard house, a somewhat low lean-to 80 feet long by 14 feet wide; it is glazed with Hartley's rough plate glass, and heated by two 4-inch pipes. The front is occupied with Peach and Nectarine trees planted in the border, and trained to the roof, which is supported by a number of light iron pillars along the centre. At each of these pillars a Vine is planted, the principal kind being Black Hamburgh. These Vines are trained under the upper part of the roof, and were in full health and vigour, and laden with a heavy crop of fine, well-shouldered bunches, numbering fully five hundred—a splendid crop, but not superior to that of last year, which I saw a little later in the season. As the fruit hangs on a level with the eyes of a person standing erect, the number of bunches appears perfectly bewildering, but notwith-

standing the attractiveness of this magnificent crop of Grapes, as one passes along the house the eye is quickly attracted by the fine healthy foliage and abundant crop of Peaches and Nectarines. It would occupy so much space were I to notice the trees individually, that I will only note here a few of the more prominent kinds. Of Peaches, Vineuse is a favourite sort; it has a fine, evenly-disposed crop. Early York is much valued for its earliness, ripening before any other kind. Among the others are Royal George, Red Magdalen, Noblesse, Barrington, and Bellegarde, highly valued for its keeping qualities. Amongst Nectarines, Monstrueuse comes first; it had an abundant crop very highly coloured, and was named to me as a splendid variety. The others are Violette Hâtive, Roman, Hunt's Tawny, and Stanwick; the last is cropping freely, but here, as at many other places, its propensity to crack has brought it somewhat into disrepute. Pausing to take one last glance, the only thing to regret was that the house was not loftier, and it might have been easily made so, by making it hip-roofed. From the skilful way in which every inch of space was turned to account, and the high state of health and fruitfulness of the whole of the occupants, I could not but think so much success must be a matter for congratulation, especially in a season like the present, of orchard-house failures.

In an early vinery adjoining, from which the Grapes had just been cleared, a few fine examples of Orchids treated on the cool-house system were looking very healthy. A fine plant of Oncidium altissimum had produced a short time previous to my visit thirteen large flower-spikes, and it was calculated that they bore at least two thousand blossoms. A Maxillaria 4 feet in diameter, Trichopilia tortilis, and Miltonia spectabilis just coming well into bloom, were the most prominent plants. At the extremity of this range is another early vinery, from which the fruit had all been taken, but the Vines were still clothed with large foliage of a deep green hue. Here were some handsome specimen zonal Pelargoniums. From these, as being of first-class excellence as pot kinds, I selected Lucius, bright rose with an abundance of large trusses; Roi de Platze, Rebecca, and Madame Mézard, very deep red; Alexandrina, a bright pink; and Louis Veuillot, a fine bold scarlet.

In front of the house last mentioned are two short ranges of glass, the first a pit in which some Melons were fruiting well, and the next a low hip-roofed Cucumber house; the plants here had been fruiting for a length of time, and a few good Cucumbers were still hanging on the trellis. The kind most liked is a hybrid bearing a close resemblance in all points to Rollisson's Telegraph. The flue by which the house is heated is carried on into a Mushroom house adjoining. A glance at the beds showed that the culture of Mushrooms was thoroughly understood. Nothing could be more satisfactory than the abundant crops of Mushrooms, varying in size from the smallest button to the full-sized Mushroom. I have frequently heard it remarked that cultivated Mushrooms are rarely equal to those gathered from a meadow. If cultivated Mushrooms could always be cooked when just expanding from the button state, this complaint would never be heard; but, in order to maintain a constant supply, some Mushrooms must always be left on the beds for a day or two after attaining maturity, and it is in these that a deficiency of tenderness and delicacy of flavour is perceptible.

On passing from this garden under an archway in the wall opposite to the orchard house, a small lean-to stove facing the pleasure grounds is the next object of interest. It contains an interesting and healthy collection of stove plants, Ferns, and Lycopods. The usual kinds of Caladiums were here too, and good plants of Alocasia metallica, Sanchezia nobilis variegata, Dioscorea marmorata, and a Gongora maculata with some fine spikes of bloom. The collection of Selaginellas is good, although many of the newer kinds are not yet grown; yet fine plants of S. variabilis, Willdenovii, umbrosa, and viticulosa must always command attention. The Ferns are well-selected and choice. I was much pleased with a handsome plant of the beautiful Pteris tricolor; a large plant of Nephrolepis distans was also conspicuous from its pretty fronds and graceful trailing habit. The Fennel-like fronds of Asplenium viviparum were also very striking. Many other elegant kinds were equally worthy of notice, but I do not think a long dry list of well-known plants can possess much interest for the general reader; I shall, therefore, conclude my notice of this house by observing that Passiflora Decaisneana trained under the greater part of the roof afforded an agreeable and useful shade to the plants beneath it.

From the stove a winding path passing through, or rather along, the margin of the lawn, leads to the conservatory and mansion. On each side of this path are groups of flower beds, in the arrangement of which no particular design is followed, yet the effect produced is very pleasing. The beds are simple in form, and are well filled with plants, the colours of which are arranged in exceedingly good taste. Some beds were so beautiful as to be quite worthy of notice. The first that attracted my attention had a broad margin of Perilla pegged closely; next this was an equally broad band of Pelargonium Crystal Palace Gem, and in the centre was a bold mass of Pelargonium Rose Queen. A circular bed had a broad margin of Mrs. Pollock, and the centre was divided into quarters with the silver-variegated Pelargonium Silver Queen. The quarters were filled with Verbena Purple King, and a plant of Ricinus purpureus major occupied the centre. The lines of Silver Queen were very skilfully planted, tall plants concealing the stem, and meeting the foliage, of the Ricinus; and from these tall plants the lines were beautifully graduated with others of suitable heights outwards and downwards to the border of Mrs. Pollock. Although this bed was very beautiful, yet had Lobelia speciosa been used in place of Purple King Verbena, the effect would have been still better. In another bed a novel and pretty effect was produced by planting a broad margin of Antennaria tomentosa; inside this margin the surface of the bed rose abruptly in a kind of miniature "ramp" a few inches high, and the centre of the bed was level with the top of the ramp, on the face of which was a single row of carefully-selected plants of the common Houseleek (Sempervivum tectorum); next this came a row of Lobelia speciosa, and the centre was filled with golden Tricolor Pelargonium Lady Cullum. A striking feature in another bed was a particularly handsome broad line of the silver Euonymus. The arrangement was—first row, Arabis variegata; second row, Alternanthera spathulata; third row, Euonymus radicans variegatus; fourth row, Lobelia speciosa, and the centre, a mass of Pelargonium Multiflorum, an excellent deep scarlet variety, of a compact, yet spreading, very free-flowering habit. I was especially struck with the simplicity both in the form and arrangement of these beds; there was no intricate geometrical design, no attempt at any of those imitations of larger places which so often prove abortive, but just a few simple beds well filled with plants of sterling merit skilfully arranged; and when the eye became dazzled with their bright hues, the broad expanse of the beautifully-kept lawn stretching away from them till it was lost under the shade of overhanging trees, offered the most agreeable repose.

The conservatory has a plain exterior, in perfect harmony with the mansion, and is a few yards distant. It may be described as a lean-to, but it has a few feet added to its original width in a rather singular manner, very much increasing its usefulness, but not adding to its beauty. This house contained the finest collection of Fuchsias it has ever been my privilege to see. Let my readers picture to themselves a bank of these beautiful flowers formed of plants ranging from 1 to 2 feet high up to enormous giant standards of 12 feet, with heads of bloom many feet in diameter. There are nearly eighty varieties, not one, but several plants of each kind, taking us as far back in the history of Fuchsias as Banks's Glory, with its closely-folded corolla, and enabling one at a glance to compare it and other old "standards" with kinds of a later date, having such expansive corollas and broad recurved sepals, as War Eagle, or Father Ignatius. There was almost every shade of colour hitherto developed in this charming family, and every plant appeared in robust health, the rich hue of the deep green foliage serving to increase the splendour of the thousands of pendent blossoms. I had, therefore, before me such a sight as is very rarely to be met with. Fuchsias, Fuchsias everywhere; in the body of the conservatory the magnificent bank I have attempted to describe; along the front of the house a row of fine pyramids plunged, and just coming into bloom, most of them being from 6 to 8 feet high, and well furnished with branches from "keel to truck;" on the side stages at each end smaller plants; and on the pillars, the stems of others whose branches were trained to the roof, their blossoms hanging in rich clusters overhead. Amongst these Madame Cornelissen was very conspicuous, its pretty blossoms of white and pink producing a charming effect. The standards at the back of the group were very fine; one of Venus de Medici must have been 12 feet high; its enormous head was a perfect mass of blossom; so was that of Banks's Glory, which was quite 4 feet in diameter, and the height was the same as that of Venus de Medici. Souvenir de Chiswick, too, had a fine head 4 feet in diameter; it was not so tall as some others, but

I considered it the most perfect specimen of a standard Fuchsia I had ever seen.

The most notable kinds in this collection were, amongst double corollas, Blue Beauty, of good habit of growth, a fine pyramid 7 feet high; Vainqueur de Puebla, white corolla, a pyramid 8 feet high; Sanspareil, double white; Humboldtii, a fine standard; Diadem; Norfolk Giant; and Serratipetala, a fine distinct kind. The base of the dark violet corolla is striped with crimson, and the edges are beautifully serrated. Of singles, the best are King of the Fuchsias, Lucrezia Borgia, with an immense mottled corolla; Constellation, having its corolla so much expanded as to be almost flat; Enoch Arden, Conquest, Roderick Dhu, Mademoiselle Tietjens, Bland's Floribunda, very free-flowering; Guiding Star, a splendid pyramid; and Alexandrina, a pyramid 7 feet high. Father Ignatius, too, was conspicuous among dark single kinds for the exquisite shape of its corolla.

As I was reluctantly turning away from the Fuchsias, I caught sight of plant after plant of the new Golden Coleuses, fairly dazzling one by their brilliancy. In speaking of Fuchsias, fine even as those I had just seen, one never thinks of applying such a term as gorgeous to them; but as regards these plants of Coleus, no other word would serve to convey a just idea of the richness of their leaf tints. I noted Queen Victoria and Baroness Rothschild as the most brilliant two kinds. Princess Royal, Her Majesty, Duke of Edinburgh, and Princess of Wales, are all very beautiful, and worthy of cultivation.

Passing across the lawn from the conservatory I noticed that all the most prominent shrubs grouped around it bore tokens of the exercise of great care in pruning, almost every shrub being a handsome specimen. The Portugal Laurels are particularly fine; one which I measured was 15 feet in diameter, 20 feet high, well clothed with foliage to the ground, and of very handsome proportions. Growing amongst the shrubs was a Paulownia imperialis, about 20 feet high, in full bloom at the time of my visit, August 16th. From the extremity of that part of the lawn opposite to the conservatory, a walk sheltered by the boughs of overhanging trees leads to an ornamental pond partly surrounded by a sloping bank of turf, on which are healthy specimens of Wellingtonias, Deodars, and Picea Pinsapo.

From this pond a walk winding among the groups of shrubs which belt the lawn leads to an enclosure, in which were some good crops of vegetables, an extensive collection of the best varieties of Gooseberries, and a plantation of Filberts laden with an enormous crop, the trees being literally covered with nuts from top to bottom. The position is certainly very sheltered, but Mr. Wraight, the gardener, attributes his success to moderate pruning; for instead of pruning the side shoots in closely, the wood is left several inches in length. Close to this enclosure is another principally occupied with well-trained pyramidal Pear and Apple trees; these have been established in their present position for several years, and up to the present time have been very productive, but some of them show signs of incipient decay, and it is quite probable that they will continue to decline. The soil of this garden is an average depth of 14 inches of loam resting on a bed of solid chalk of great thickness. In such a shallow soil fruit trees naturally develope their fruiting properties very early, and as the roots are so near the surface the production of blossom buds would doubtless be very far in excess of that of wood buds, and consequently the trees would, if permitted, go on producing a heavy crop of fruit annually with but very little wood growth; moreover, trees growing in so shallow a soil must be very susceptible of atmospheric influences, and, therefore, after so trying a summer as that of 1868, unless materials for mulching and a good supply of water could be had, trees so situated would be almost certain to exhibit signs of constitutional debility, brought on by the severe trial to which they have been subjected.

I have thus attempted to describe the more prominent features of this attractive place, and whether taken in its several departments or as a whole, nothing can be more satisfactory; everything gives evidence of being cared for with the skill, energy, and intelligence of Mr. Wraight, under whom these gardens have been gradually moulded into their present form. Nor must I conclude these notes without referring to Mr. Wraight's devotion to the science of entomology. In years gone by, when we were neighbours, many a race have we had together after some vagrant member of the Lepidopterous family. That my friend has met with as great a share of success in this pursuit as he has amongst his plants, is evident from several cases of "subjects" suspended on the walls of his cottage.—Edward Luckhurst, *Egerton House Gardens, Kent.*

THE MANETTI ROSE AS A STOCK.

Will some of your correspondents furnish me with their opinions of the Manetti stock as a substitute for the wild Rose? I have heard it condemned as an imposition on amateurs, while a great success in a commercial point of view. Does it, or does it not, eventually suffocate the scion by the very rapid and strong growth which is said by some to constitute it a sure money-maker for nurserymen?—C. A. G.

[We asked the Rev. W. F. Radclyffe for his opinion on the subject of the above query, and now publish his reply. There have been so many doubts upon the subject that we shall be obliged by reports of the experience of other practical men, cultivators of Roses in other soils and localities:—

"The Briar, or wild Rose, is a capital stock for strong cold land, such as rich clay or strong loams. It is not a good stock for light hot lands, so far as Hybrid Perpetuals are concerned. It is curious but true, that in light lands strong growers such as the summer Roses and Tea-scented Noisettes, do well on the Briar. The others do not grow strongly enough to keep the Briar healthy. For dry lands, unsuitable to the Briar, the Manetti stock is best. It is, moreover, more defensible than the exposed Briar. In strong lands the Manetti stock drives the Rose into pole-stuff. In such a case the plant must be severely root-pruned or removed annually, and little or no manure given. The Manetti stock is not an imposition. The failure of Roses on this stock has arisen from propagators budding the Rose so high on the stock, and from persons not planting the Rose sufficiently deep to cover the stock over the point of union. Budding on the Manetti is the easiest way to obtain Roses on their own roots. Before you plant the Manetti-stocked Rose, cut out all the eyes in the stock; then plant the Rose, treading the earth close up to the stock, which will prevent brood. If the land is poor put earth over the roots, and then a layer of rotten dung alternately with earth, and tie the Rose to a stake. Do not cut the Rose back till spring. Never prune any Rose at planting time. Prune your Rose on the Manetti stock, as if it were a Hybrid China; merely thin out useless stuff, and cut the shoots and branches to a good eye. If the plant should be seriously affected with chlorosis all over, you had better in spring cut it down, as good wood cannot come from bad wood.—W. F. Radclyffe."]

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Cypripedium Parishii (Rev. Mr. Parish's Lady's Slipper). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Diandria.—Native of the Moulmein Mountains. A superb species. Purple and green.—(*Bot. Mag.*, *t.* 5791).

Ceropegia Sandersoni (Mr. Sanderson's Ceropegia). *Nat. ord.*, Asclepiadaceæ. *Linn.*, Pentandria Monogynia.—Native of Natal, on the banks of the Umgeni river. Flowers very conspicuous, though pale green spotted with dark green. A tall climber.—(*Ibid.*, *t.* 5792.)

Acer rufinerve *var.* albo-limbatum (White-edged, red-nerved Maple). *Nat. ord.*, Sapindaceæ. *Linn.*, Polygamia Octandria.—Native of very different climates in various parts of Japan.—(*Ibid.*, *t.* 5793.)

Primula Pedemontana (Piedmontese Primrose). *Nat. ord.*, Primulaceæ. *Linn.*, Pentandria Monogynia.—Native, and a lovely one, of the high Alps of Piedmont and Switzerland. Flowers purplish rose.—(*Ibid.*, *t.* 5794.)

Dorstenia argentata (Silver-leaved Dorstenia). *Nat. ord.*, Moraceæ. *Linn.*, Monœcia Diandria.—A stove variegated-leaved plant from South Brazil. Leaves dark green, white-centred, marbled with paler green.—(*Ibid.*, *t.* 5795.)

Rhododendron *Mrs. John Clutton.*—"This variety is considered by competent judges to be the best hardy white at present in cultivation. It has all the symmetry of truss, and smoothness of form and outline, that the most fastidious could desire; it is a remarkably free-bloomer; its flowers, from their thick and waxy texture, are, moreover, most enduring; and it comes in late, so that it is not often frost-blitten. The colour is white, just at first showing the slightest tint of blush, which passes off as the flowers become matured, when it stands out conspicuous by its purity—indeed, Purity itself, another ex-

cellent white variety, is quite surpassed by it in all essential points of merit,—truss, form, colour, and season. The pyramidal outline of the truss, with the flowers regularly disposed, each supporting its neighbour, is as near perfection as need be desired, while the smooth outline of the blossoms adds very greatly to its charms in the eyes of connoisseurs. Rhododendron Mrs. John Clutton was raised from the variety named Album elegans, in the marvellous collection at Mr. Anthony Waterer's, Knaphill Nursery, Woking."—(*Florist and Pomologist*, 3 s., ii., 193.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

The wet weather we have had lately has encouraged the growth of weeds, and rendered their destruction a matter of difficulty. The best way to destroy them, when hoeing and raking are not practicable, is to dig them down, especially the young generation. *Cardoons* and *Celery*, earth-up at all favourable opportunities. The latest of the Celery plants may be planted without making ridges for them, using for manure only a little leaf mould and charred earth; they will come in for soups, and will keep up the supply till May or June. The strongest plants of the early *Cabbages* may be planted out for late Coleworts. The main crop to stand the winter must be planted now in well-manured ground; this is a most important crop, and larger breadths ought to be planted than is usual. Plant plenty of *Endive* near walls and wooden fences, to stand the winter. Let all the old *Scarlet Runner* pods be picked off, except a few of the best for seed, as they exhaust the plants for a succession. *Winter Spinach* must be thinned, working the hoe well through to loosen the soil. *Turnips*, thin the latest crop. *Lettuce* for the last autumn supply, put in some strong plants of the Bath Cos in a warm sheltered situation, scattering plenty of charred earth on the surface to annoy the slugs. Gather *Camomile* flowers, &c. *Basil* and *Sweet Marjoram* should be bunched and packed in a close box to preserve their aromatic flavour. But little sowing is now required, presuming that all the Cauliflowers, Lettuces, Cabbages, and Spinach have been sown in August. A patch of frame *Radish* may be occasionally tried according to the consumption.

FRUIT GARDEN.

Disbud and stop Fig trees, and stop the points of all strong-growing Peach and Nectarine trees; take away all nails in the way of fruit swelling. As previously recommended, frequently look over fruit remaining out of doors, and gather it as it becomes fit; also, examine that stored in the fruit room, as there will occasionally be found a few decaying for some weeks after housing, and such should be removed as soon as perceived. Keep the fruit room cool and well aired, in order to allow of the escape of the moisture given off by the fruit, which is considerable for a few weeks at first. Where it is intended to make fresh plantations of fruit trees this season, the ground should be prepared at the earliest convenience, and any fresh soil to be used for planting should be thoroughly exposed to the action of the weather, so as to have it in a mellow state when wanted for use. If not already done, clean and dress Strawberry plantations, clearing away all useless runners, and giving a good dressing of manure when necessary, but be careful to select that which is thoroughly decayed, and which can be covered without the necessity of digging deeply or injuring the roots.

FLOWER GARDEN.

The principal work in this department for the present will be mowing and clearing up, and if neatness is to be maintained sweeping up leaves will now require daily attention; also, keep gravel walks free of weeds and moss, and roll them frequently when wet. Continue to afford young plants in pits and frames the most careful attention, and endeavour to have them well rooted and strong, without keeping them so close or warm as to render them soft and liable to fog off on the first approach of winter. Admit air freely to all plants that are sufficiently rooted to bear it without flagging. Plants newly potted off should, however, be placed in a gentle bottom heat, which will impart a little warmth to the soil, and encourage the formation of roots, but sufficient air should be given to prevent anything like weakly growth. Cuttings of Scarlet Pelargoniums may still be put in where the stock is deficient. Scarlet Pelargoniums will root almost anywhere. See to securing as many cuttings as possible of any scarce plants which it may be desirable to increase, while there is a fair chance of rooting them; also, be prepared to protect Pelargoniums and other plants which it may be intended to take up and winter, for we may expect frost any time after this season; and if such plants can be protected, so as to prevent the foliage and young wood from being much injured, they are much more easily wintered. Where annuals have sown themselves on borders let them, if possible, be retained; they will bloom early and strongly in spring, especially the Californian kinds, and may then, if desired, be transplanted to other situations.

GREENHOUSE AND CONSERVATORY.

If the season continue mild—that is, if the thermometer do not fall below the freezing point, I should recommend full exposure for the Heaths and greenhouse plants for a week or two longer. These remarks apply more to hardwooded plants than to Pelargoniums, and the like; but even with any plants, if the weather is tolerably fine, it is not advisable to commence housing them too soon, except in situations where the lights can be removed during the day. No time, however, must be lost in preparing the houses for the reception of the plants, by cleaning every part thoroughly, and by forwarding such repairs as may be necessary. The pots in which the plants are growing should also be made thoroughly clean, so that should any change of weather occur, no delay may be experienced in housing them; and if time can be spared to have the plants all neatly staked, they will look all the better, though staking may be performed during the winter. All specimens should have been potted before this time, but if any remain, it will be better to pot them now than to leave them pothound throughout the winter. Acacias and other winter-flowering plants, having been subjected to a period of comparatively dry treatment to insure their blooming profusely, should now be supplied rather liberally with water at the roots, in order to bring them into flower during the dull season. They will then be much more esteemed than in spring, when flowers are plentiful. Manure water, if it can be used, should be given frequently to Chrysanthemums. Give air freely on favourable occasions, avoiding cold draughts against plants that have been brought from a warm house, and guard against damp by using gentle fires, with a little top air on wet days. Let pot specimens in bloom be frequently re-arranged, so as to make the most of them, for the finest specimens become too familiar to be interesting when allowed to remain too long in one place. Be careful not to overwater plants brought from the stove, and also to use the water in a tepid state. Use weak liquid manure for Salvia splendens, so as to preserve the plants in a vigorous state, and keep them blooming as long as possible. Pay attention to securing a plentiful succession of plants for maintaining the gaiety of the house during the winter. Of routine work, Violets must either be potted, or placed in their blooming frames before long. Attend to Mignonette, by thinning it in time. Pot Intermediate Stocks for early blooming, also a few annuals for the same purpose. Tropæolums must also be started, and no time must be lost in procuring and potting such Hyacinths, Tulips, and other bulbs as may be required for forcing. Place Chrysanthemums, Cinerarias, &c., under cover as soon as possible.

STOVE.

Give abundance of air here at every convenient opportunity, and assist the plants to complete their growth in a strong and healthy manner. Do not attempt to bring plants which are growing prematurely to rest, because of ripening the growth, but keep them steadily growing until they go gradually into a state of rest. Many stove plants, especially Ixoras, may be induced to make as much growth during the winter as in the summer, and there are other plants which will do the same. Sprinkle the walls and pathways twice or thrice daily, and bedew the plants occasionally with tepid water on bright days. Maintain a brisk temperature during the day, but allow the thermometer to fall to about 60° during the night.—W. Keane.

DOINGS OF THE LAST WEEK.

For nearly a week we have had rain and wind every day, the wind at times approaching a tempest. The weather on the whole has been favourable to root and grass crops. Woods and plantations have been thinned of their rotten branches and weaker twigs by the wind, and even trees in pleasure grounds found its force, and so far bent before its influence; but with us little or no damage was done. We hear of sad wrecks made in many flower gardens. Here, exposed as we are, the wind did little injury except to some lofty Hollyhocks that escaped from their tyings, though few were broken. The flower beds, which were much exposed, were anything but bright; but others,

protected as a border in front of a wall, suffered but little from the effects of the wind and rain. We hear much of broken plants, and the soft tops of Pelargoniums, Calceolarias, &c., careering over parks and fields, but of this we have had no experience; and yet no place could well be more liable to injury from the force of a gale, unless entirely exposed on the windy side of a mountain. We attribute our security from breakages to rather thick planting and bush-sticking every bed and border as planted. This takes some time at planting, but it makes us comparatively safe, which we never were before resorting to the practice. Of course these bushy twigs and branches do not look over-inviting in the beginning of June, though even then they may be put in neatly, and the object seen does away with the feeling of roughness and want of neatness. In a good growing season the sticks are soon concealed, and as the summer advances, if a few twigs show beyond the plants and their blooms, they are easily nipped off with the point of the knife. We are not aware that a single plant has been broken in the flower beds, though many of the plants are rather brittle, and this in such storms we attribute to the plants being secured by a network of twigs. There is no analogy in results between using such twiggy branchlets, and straight sticks or stakes and tying. Very little tying is wanted with the twiggy branchlets. We take anything at a pinch—the small ends of Hazel branches, the twiggy pieces of Larch branches; but the best of all are those of Spruce, especially the points of the branches, after they have lain long enough to drop all their foliage. If such have been used as the bottoms of stacks, &c., all the better, as the weight makes them straighter. These, according to the size of the plants to be sticked, are cut in lengths of from 15 to 30 or more inches, and the more side shoots and twigs these short fan-like sticks have, the better do they answer. The branches and shoots of the flowering plants grow through the twigs, and it requires more wind than we have yet had this season to dislodge them. We remarked lately that if the weather became fine after the rains, the beds would again be beautiful. All the week until the 17th we had dull showery weather when there was not a gale. On the 17th we had much sun, and a dry morning without dew, so much so that we used our grass-cutters at 6 A.M., and by the afternoon the beds had regained something of their former brilliancy. So far as the flower garden is concerned, the autumn display will depend on dryness and sunshine. We hope to see it good for at least a month or six weeks.

KITCHEN GARDEN.

Celery.—The rains having given a good soaking to the Celery ground, a part of what had been previously tied had a good earthing-up at once. For what would be taken up early we used the common soil at the sides, from which a row of Peas had just been removed; but for that which would stand longer we put a little ashes from our furnaces round the plants—that is, a thin layer of ashes between the plants and the earth, which helps to keep worms and slugs from disfiguring the stems. An easy mode of doing this is to have some semi-circular pieces of tin or zinc, such as pieces of old house-spouting, &c., in lengths, say, of 15 or 18 inches, two of these nearly to enclose the plant and receive the riddled dry ashes inside. When the earth is applied the tins are drawn up, and the earth pressed firmly to the ashes. When ashes are plentiful, it is a good method after earthing-up to throw some with a spade all over the bed, as it helps to keep soft-skinned intruders away. Took the opportunity of such a dry day as Friday to clean and tie up more beds of Celery, and just put a sprinkling of finely pulverised soil from the sides over the roots. This will help to keep the moisture in if dry weather should follow.

A single fact is often worth a number of inferences. That fact clearly shows us all that has been advanced on the bit-by-bit earthing-up of early Celery is based on a principle that scarcely permits of error. On examining some Celery washed and ready for use, we noticed it was harder and firmer to the touch than it ought to be, so as to be short and crisp, as well as sweet, the three essentials for good table Celery as an accompaniment to cheese, &c. That Celery had been thoroughly soaked more than once before earthing-up, and yet on taking up some roots we found these dry enough. The tops of the leaves exposed had evaporated all the barrels of moisture we had given in the parching weather. That Celery had been earthed-up at once. If we had put the earth to at three or four times, and without fresh watering, we should have expected almost every plant to have thrown up its flowerstalk. If the weather had continued dry and hot, we should have expected the same result. No rains that fell would ever reach the roots; they would only act in lessening evaporation from the foliage. Openings and holes were therefore made between the rows, and enough of water poured down to saturate the soil at the roots, and now the Celery is crisp as it ought to be. The man who gave the last waterings before earthing-up could scarcely believe that it was possible for the great mass of roots to become so dust-dry. There are few plants that evaporate more moisture than Celery in a hot sunny day. By this or other means allow the roots to become dust-dry, and in self-defence the plant will throw up its flowerstalk to perpetuate the race. The same principle holds true in all vegetable growth. A severe check to luxuriance is the most effectual mode of securing early flowering and seeding.

House Sewage.—Let us once more impress the importance of the use of this on our cottager readers. For most growing crops belonging to the Cabbage family it is invaluable, if not given too strong, and that can be remedied where other water is to be had. In general the water that comes from laundry, scullery, &c., will not be too strong for such gross feeders. It may be applied at any time, but a good watering before rain is expected tells most quickly and surely. We would have used more could we have obtained it. A border of Cauliflowers showing the dull slaty appearance of the foliage, had a dose on the 8th, and that and the rains of the 10th, and onwards, have wrought wonders.

As far as our own observation and experience go, we think too much has been said about deodorising liquid manure. We would be bold enough to say, that to produce the greatest effect, it should be used fresh enough to save all trouble about deodorising. We have noticed a very marked difference in the effects on grass land and growing crops between using liquid manure after it had fermented in a reservoir, and similar liquid used before fermentation had taken place, or to a very limited degree. The fresher the liquid the more effective it was; the ammonia, &c., was not dissipated before using it. People have fallen into the habit of valuing a manure in proportion to the nasty scent that comes from it. Now, as a break-in on the old idea, it would be a step in the right direction if we could convince ourselves that liquid manure, if equally strong, would be more effectual before it had acquired the unpleasant scent than after it had done so. A very successful farmer, who keeps a large stock, looks sharply after his manure tank, and reduces its strength when too strong, but whenever practicable he puts it on the ground in its fresh unfermented state. The extent to which the manure-water cart had gone could be seen easily in Barley, hay, pasture, &c. Even where a crop of hay had been taken, the young grass had a deeper green than the other parts of the field. He found that even when applied to grass pastures rather strong, so as to brown the young herbage at first, the roots were so nourished that soon all trace of the injury was lost. In gardens it is easy to avoid wetting the leaves when applying it to the soil and roots. As already stated, it is most effective when applied before rains. Strong liquid manure, consisting chiefly of the urine of animals, should be diluted with five times its quantity of water before using it.

FRUIT GARDEN.

The winds have shaken the fruit very much from tall trees, but though some has fallen, comparatively little harm has been done on low bushes or pyramids. We have no objection to old-fashioned orchards, and especially when the under crop is grass, manured at times. Those are excellent for insuring always an abundant supply to an establishment, and the gardener is little troubled, if a few trees should be barren each year, which he must be if he has only a few trees altogether in a kitchen garden to depend upon. But where room is to be made the most of, and the greatest pleasure is to be derived from the culture of fruit trees, commend us to low bushes or pyramids—say from 6 to 8 feet in height. The wind will have but little power on these, comparatively speaking, and the fruit is easily examined, and easily gathered. If we had the chance, we should be inclined in small gardens to adopt the cordon system of training—that is, having only one or two shoots from a tree, and spurring them from top to bottom. We have little faith in mere fanciful modes of training, but by the one-shoot system a great variety can be grown in little space, and each kind on its own bottom, as it were. We believe that great results may be achieved by this plan in small gardens, where the lines of fruiting stems can be kept near the ground, and a protection given in severe weather.

We have heard that several of our readers no farther north than we are, have had Williams' Bon Chrêtien Pear fit for use

naturally for some time past. We could only gather some fit for use by the 14th, and that after giving them a help with artificial heat for a week. This is a Pear in flavour by itself, but it will only keep a short time if not gathered frequently, selecting the most forward fruit first, and giving them a little help. We have thus had it six weeks from the same tree, and that not a large one. It should be observed, that in forcing after gathering, the Pears should not be exposed so as to lose their moisture. We prefer placing them in a pot, with a covering of paper and sweet hay over them, and a stout cloth tied over the pot. Other conveniences might be neater and better; the only thing is, in forwarding the mellow ripening, not to deprive the Pear of its natural juices, otherwise it will be apt to eat either hard, or soft and sleepy. This Pear is worth a little trouble.

We have had some fine Figs from the open wall, where no training was attempted, the shoots being left to dangle from the wall. Some of these were larger in winter than usual, but passed through it without protection, owing to its mildness. These are higher-coloured and firmer in texture than those we have under glass. We gathered a few at the end of August, and more at the beginning of September, the earliest that we have gathered out of doors in this district. Of course, it is nothing to those who live in the sunny south, as in Devonshire. We shall never forget the sight of the row of low standard Fig trees at Mamhead, and the weight of large luscious fruit they carried. It is well to have all the shortening and regulating of the summer shoots of fruit trees finished, so that the autumn sun shall have less to do in insuring maturation of the wood. In shortening the shoots of Peach and Nectarine trees, it is best to shorten to a wood or triple bud, as some old trees produce wood buds rather sparingly. All who contemplate planting fruit trees in houses or out of doors, should bear in mind, that if that work is done in October, even if towards the end of it, nearly a season will be gained over those trees planted in March, or later. Where time can be found, it is well to prepare for planting, by trenching, border-making, or preparing small stations for the well-being of the tree, whilst the bulk of the ground remains at first untouched or unprepared. It should be kept in mind, that fruitfulness and luxuriance are over opposed to each other; therefore, avoid much dung, and the little used should be sweet. Deep rooting encourages growth, shallow rooting encourages fruitfulness; therefore, keep the roots near the surface, and if more vigour is necessary give that vigour by surface dressings. These matters attended to, pruning at the top, and especially pruning at the roots, will be less necessary.

ORNAMENTAL DEPARTMENT.

As already stated, we do not yet despair of a fine autumn display; but everything will depend on sunshine. Several times we have had Scarlet Pelargoniums and Calceolarias better in the end of October than in July; and at any rate we shall not again suffer from drought this season. Our lawn never was brown this season, but it was beginning to turn so, and now it is beautifully green, just the colour to show off brighter hues to the best advantage. Looked at separately, we never had finer groups of Scarlet Pelargoniums than last year, but then they looked so out of place with a burned-up lawn alongside of them.

Annuals.—We could not use our flower beds for sowing; but we sowed in a border rather thickly in rows, to bloom there, or be transplanted in spring, such annuals as Nemophilas, Clarkias, Giliaa, Erysimums, Godetias, Collinsias, especially bicolor, Sanvitalia, Saponaria, Silenes, especially varieties of pendula, along with Candytufts, Alyssum, and Virginian Stocks. The last three will bloom early in winter if it be mild, and will come in as an addition to cut flowers. The ground for these, if enriched at all, should merely have a little very rotten and sweet manure forked in at the surface; and the soil, if mellow, should not be deeply stirred if transplanting afterwards is the principal object, as it is in general best to raise the seedlings that have come up thickly, not singly, but in little tufts, and plant with a ball adhering to them. The chief difficulty in making a fine show with these and bulbs, Daisies, Heartsease, Forget-me-nots, &c., in spring, and yet having beds brilliant in summer and autumn, arises from the unwillingness of the owners of flower gardens fully to appreciate the simple fact, that to do this a reserve garden for storing and growing, and more labour power, are absolutely essential.

We gave plenty of air to seedlings, in pots, of Mignonette, Schizanthus, Stocks, and annuals intended for blooming early in spring. When a little heat can be given in a frame in spring, we prefer sowing Mignonette early then, instead of making a second sowing now, involving the trouble of protecting it during the winter. Many common plants grown in pots come in useful for cut flowers when house flowers are scarce.

Our Violets, Neapolitan and others, are not so clean as we would wish, otherwise we should soon take them up and pot them, or replant them in a bed or pit. The rains will help to clear away the last of the red spider that attacked them when we were short of water. Looked over many plants whose blooming was over, as Achimenes, and set them in a dry place, where, from receiving little water, they might perfect their tubers. Now is a good time to pot the most forward lot of bulbs, as the more naturally they fill the pots with roots before starting them by forcing the better they will succeed. Proceeded as far as we could with putting in cuttings for next season, delaying as long as possible for reasons recently stated. As to looking after greenhouse plants out of doors, see recent notices. Potted Cinerarias and Primulas for early flowering, and inserted cuttings of the best kinds of Coleus, that we may be able to keep them in little room in winter, and so dispense with the large plants that would take up much space. For out-door display, Coleus Verschaffelti is best with us. It has stood the weather remarkably well; all others suffered more from the drought, and the wind and rain. A brownish Coleus, Berkleyi, is, perhaps, the next best. All of them would make splendid beds under glass. No doubt in warm places—about London and south of it, most of the varieties will do well out of doors. Here we succeed with Coleus Verschaffelti by planting strong plants late—not until the end of June at the earliest.—R. F.

COVENT GARDEN MARKET.—September 22.

The arrivals of foreign produce have been considerably lighter this week, and we have very little gathered fruit, but the windfalls exceed in quantity anything that has been known for many years. Pears consist of Williams's Bon Chrétien, Duchesse d'Angoulême, Louise Bonne, and Brown Beurré; Apples of Ribston Pippin, King of the Pippins, and Kerry Pippin. Potatoes are plentiful. Complaints of supertubering and blight have reached us from heavy clay lands, but are not generally confirmed.

TRADE CATALOGUES RECEIVED.

André Leroy, Angers, France.—*Supplément au Catalogue de* 1868.—*Tableau des arbres Forestiers et d'Ornement deja forts.*

Jabez J. Chater, Gonville Nurseries, Cambridge.—*General Descriptive Catalogue.*

TO CORRESPONDENTS.

Auricula, Howard's Eclipse.—"*Auricula*" says that many years ago there appeared in "Harrison's Cabinet," some notice of an Auricula called Howard's Eclipse, grey edge, and wishes to know if anyone can supply him.

Black Pansy (*Peter*).—There can be no objection to the name, although there are several Pansies with flowers as dark and much better. As for the Pelargoniums, &c., they were far inferior to kinds now commonly grown.

Pansies at the Hamburg Show (*S. S.*).—The exhibitor of the Fancy Pansies, noticed in our report of this Show, is a nurseryman, his full address being—Herr H. Wrede, Handelsgärtner, Lüneburg, Hanover.

Select Gladioli (*W. H. M.*).—At the prices you state, the following would be a good selection:—Bernard Palissy, Fulton, James Veitch, Le Dante, Madame Eugène Verdier, Apollon, Madame Vilmorin, Noëmi, Madame Basseville, Duc de Malakoff, Comte do Morny, Le Poussin, Sir Walter Scott, Stuart Lowe, Adèle Souchet, Peter Lawson, James Carter, Ophir, Stephenson, Reine Victoria, Belle Gabrielle, Madame de Vatry, Marie Dumortier, and Madame Binder.

Six Single and Double Hyacinths (*St. Edmunds*).—The following are cheap and good:—Charles Dickens, light blue; Baron Von Tayll, dark blue; Madame Hodgson, pale pink, striped; La Tour d'Auvergne, double, white; Laurens Koster, double, dark blue; Grootvorst, double, blush.

Tacsonia Van-Volxemi Pruning (——).—The leading shoots, as well as the laterals, produce flowers. As yours is a young plant, we would not prune it at all this autumn or next spring, but train-in the shoots as they grow, not nearer each other than 6 inches, and at from 6 to 9 inches from the glass, and where too close together thin them out. You may stop the shoots in order to produce more side shoots for covering the trellis. Keep the plant rather dry during the winter. After it is established, and has grown to the extent required, it may in February be pruned-in or spurred like a Vine, leaving two or three eyes on the side shoots for the production of shoots in summer for flowering. Summer pruning ought to be confined to thinning out the shoots where too crowded, and training them in moderately thinly, so as to afford every part a sufficiency of light and air. If the shoots do not push at the places required, stop them, in order to obtain enough of shoots for covering the trellis. We prefer the rod system of pruning and training, cutting out the shoots which have flowered, and supplying their places with young shoots, which are produced plentifully from the base of the plant.

Cyperus alternifolius variegatus Leaves Browning (*Idem*).—The cause is the sun shining on the leaves whilst wet. They would not be liable to injury from this cause if air were given early, so as to dissipate the moisture before the sun became powerful. We grow the plant in sand, in order to have the leaves well variegated. From April to October the pots should be set in saucers of water kept full, and in winter keep them rather drier. Want of water will cause the leaves to wither and brown, as yours appear to have done. A warm greenhouse, or one having a heat of from 45° to 50° at night, is the more suitable place to winter them in. We cannot name plants from leaves only, flowers are needed.

Propagation of Grevillea, Hakea, &c. (*F. G.*).—Take cuttings of the young shoots when they are ripened at the base. They should be about 3 inches long. Cut across below a joint, trim off the leaflets for about 1 to 1½ inch up the cuttings, and insert them about an inch apart round the side of a well-drained pot, filled to within an inch of the rim with sandy peat, and to the top with silver sand. The pot should be placed in one of larger size, the interval between the sides of the two being filled with crocks to within an inch of the rim, and then with a little moss, surfacing with silver sand, on which a bell-glass should rest. A gentle watering should be given after putting in the cuttings, but do not cover them with the bell-glass until they are dry. Place them in a cool house, shade them from bright sun, and do not water them, or give only a sprinkling to keep the soil just moist. If much moisture condense on the bell-glass, take it off occasionally, wipe it dry, and replace it immediately. In about a month a callus will be formed, and then give a gentle bottom heat of 65° or 70°, and when the cuttings begin to grow, tilt the glass a little on one side, removing it by degrees. We cannot name plants from leaves. A better specimen and flowers are necessary for identification.

Fuchsia Leaves Falling (*An Old Subscriber*).—Some of the leaves are infested with red spider, others with thrips, both a result of the atmosphere being too dry and hot. The plants ought to have been syringed with water twice a-day, and a moist atmosphere maintained by sprinkling the paths, &c., with water two or three times a-day. We would shut the house up closely, fumigate with tobacco, and give the plants a few forcible syringings. The plants will not be of any use this year. Place them out of doors for a month, and take them in before frost.

Wintering Greenhouse Plants in a Room (*Devon*).—The plants you name could not be wintered well in a barn or empty room. They might survive the winter if it be mild, but the darkness would cause the leaves to fall or render them useless. You may try them, however, not giving more water than sufficient to keep the plants alive, and let them have all the light and air you can in dry and mild weather. We have seen Orange trees, Aloes, Cacti, &c., wintered by such means tolerably well, and there was no more light than that admitted by oiled-paper side lights, wooden shutters being put up in severe weather.

Plants for Exhibition to Bloom in May (*Inquirer*).—*Bulbous:* Ornithogalum aureum, Stenomesson breviflolium, Asphodelus albus, Corydalis nobilis, Ranunculus bullatus, Trillium grandiflorum. *Herbaceous:* Dielytra spectabilis, Aquilegia alpina, Campannla pyramidalis, Convallaria majalis variegata, Myosotis alpicola, Ajuga alpina.

Early Potatoes (*Idem*).—Royal Ashleaf, Huntingdon, both kidney-shaped, and Coldstream, a round sort.

Wellingtonia gigantea Fruiting (*J. T. K.*).—We have made some inquiry, but we cannot hear of this tree having ever perfected its cones, so as to produce good seed, but there is no reason why it should not do so when the specimens are older. Mr. Robson says that as far back as 1863 one or two of his young trees showed signs of fruiting when scarcely 4 feet high; but a more vigorous growth taking place, the fruits dropped off or did not ripen. In 1866 a robust, fast-growing specimen produced a cone, which, he says, never became larger than a full-sized hen's egg, although it remained on the tree for three summers. This year the tree, a very fine specimen, 18 or 19 feet high, has a fair crop upon it, the cones being mostly produced at the tips of the shoots; being in clusters, they have a pretty appearance. He also says his cones are mostly globular and not conical, and some are egg-shaped, but the end not pointed. He is not anxious to see either this or any other Conifer in fruit at so early an age, as growth is checked in consequence, and an appearance of premature old age is brought on. He would, therefore, advise you to pick off the greater portion of the cones on your tree, reserving only a few of the best for novelty, and to see if good seed is likely to be produced.

Wintering Seedling Roses (*Amateur Rosarian*).—Instead of wintering the plants in the frames, we should prepare a bed for them in the open ground. After digging it deeply and working in the manure liberally, we would plant out at once—those from the pots about 2 feet apart, and those from the box, which are upwards of 3 inches high, about 1 foot apart. Mulch with litter in November, before severe frost. The plants have done very well—sown in February, now 18 or 20 inches high, and some of them flowered. By planting them out you will be able to see what they are, for as they will grow more vigorously from being planted out they will be more in character. If they are Tea-scented, or delicate sorts, the plants should be wintered in the frames, plunging the pots in coal ashes, and planting-out in April. They cannot have too much air while in the frames. Protection must be afforded from heavy rains, and in severe weather put on a covering of mats in addition to the lights. Dust with flowers of sulphur any that may be mildewed.

Roses in Pots (*M. E. T.*).—Anna Alexieff, Jules Margottin, Senateur Vaisse, Lælia, Général Jacqueminot, Marie Baumann, Madame Victor Verdier, Victor Verdier, Maurice Bernardin, Pierre Notting, Catherine Guillot, Paul Pérras, Madame Willermoz, Alba rosea, Madame Bravy, Madame de St. Joseph, President, Souvenir d'un Ami, Maréchal Niel, Triomphe de Rennes, Céline Forestier. The Tea Roses on their own roots, the others either on their own roots or budded. Let the Jerusalem Artichokes alone till you take them up.

Budding and Removing Roses (*Nanny*).—"You can move your budded Roses to their intended places now, in November, or in the spring. Be careful with the network of roots. Briar stocks should have roots. Cuttings will not succeed. Why did you not put your Briar stocks in the places intended for future occupation, and bud them there?—W. F. Radclyffe."

Leaves of Peaches and Nectarines (*C. G.*).—There is no difference in their form or other characters.

Peach Shoots Mildewed (*J. H., Amateur*).—The shoot sent is severely mildewed. It is induced by an insufficient supply of water at the root. It may be destroyed by dusting with flowers of sulphur. Any trees having shoots green and unripe, like the end of the one sent, ought to be pinched off to check growth and promote the ripening of the wood. Shifting the trees into larger pots would be desirable next month, not disturbing the roots, however; pot whilst the leaves are on, and you will from the descending sap secure a certain amount of root action this autumn. Give as much air as you can, and keep a dry atmosphere; for the wood, we should say, is far from ripe. If you have means of affording gentle fire heat, apply it, accompanying it with air day and night. Lessen the supply of water to the roots.

Black Hamburgh Grapes Shrinking (*Subscriber, E. P.*).—The Grape are being converted into raisins from the great heat we have had lately. We do not know what would have made them more juicy except supplying them more plentifully with water at the roots, and maintaining a moister atmosphere when they were ripening. After they were ripe, the house should have been kept cool and dry. Long-hanging Grapes do not contain so much juice as those newly ripe.

Vine Leaves (*J. T., Copenhagen Street*).—We cannot name Vines from their leaves; we must see the Grapes too.

Vines (*R. Impey*).—We think your proposed plan of planting would do very well; but why not have a Vine on each side until the more strong-growing one occupies the full width of both sides of the span?

Gooseberries (*P. J. H.*).—London, Leader, Thumper, and Hero of the Nile will produce the largest berries. Write to some friend at Manchester or Sheffield to purchase plants for you.

Transplanting Currant and Gooseberry Bushes (*A Regular Subscriber*).—The best time to transplant them is as soon as the leaves turn yellow and are falling. Moist weather is best.

Removing Figs (*G. C.*).—You may remove all the large green Figs this autumn, as they rarely survive the winter. Those not larger than a hazel nut should be retained. We presume your trees are against an open wall. If the trees are in pots, or in borders under glass, no part of the crop ought to be removed, as those now on the trees will be the first to ripen next May or June.

Stapelia speciosa Fruiting (*Love Apple*).—It is rather unusual for this plant to fruit. We have no doubt you might dispose of the Stephanotis seed. Write to one of the principal London seedsmen.

Cupressus torulosa Propagation (*H. L.*).—Take cuttings now of the well-ripened shoots of the current year's growth, from 3 to 6 inches long, and insert them rather thickly round the sides of 6-inch pots, draining these well, and filling them to within an inch of the rim with sandy loam two parts, and one part sandy peat, then to the rim with silver sand. Cut the shoots across below a joint, and insert them about 1 or 1½ inch in the soil or sand, and not more than 2 inches. Give them a gentle watering, place them in a cold frame or under a hand-glass in a cold house, and keep them close, shading in bright weather. Sprinkle them with water occasionally so as to keep the soil moist, but not very wet. They will strike root slowly but surely, and be well rooted in from six to twelve months, when they may be potted, hardened-off, and planted out. Do you find it succeed in the smoky atmosphere of the town you name?

Climber for a London House-front (*Charles Ellis*).—The Vine will suit your purpose, but the Virginian Creeper will grow quicker. But for the slowness of growth the White Jasmine flourishes delightfully in London. For a screen for the window as you propose, nothing will answer better than Ivy, and for the position, we would prefer the green to the variegated Ivy. The box should be in two distinct divisions, one for the Ivy roots, the other for the flowering plants.

Hot-water Tank (*M. B.*).—You will do what you propose with your tanks, if you have a return-pipe from them as well as a flow into them, and divide each tank down the middle, except a space at the farther end, and if you cover with iron or slate instead of wood. We have no faith in your succeeding with a wood covering. Provided the cover is all right, we would prefer sand to cocoa-nut fibre for setting the pots in.

Repotting Lilium auratum (*W. A. O.*).—We would not repot the bulbs potted last year if the drainage is good, but we should remove the surface soil as you propose, and give a top-dressing of rich compost between now and February, and again between then and June. If you pot them, do not disturb the roots, but, removing the soil and drainage, pot with the

ball entire. All bulbous plants are impatient of having their roots disturbed.

PELARGONIUM PROPAGATION IN LOOKER'S BOXES (*Ignorance*).—You should fill the pan with broken pots or cinders to within 9 inches of the glass, covering them with a thin layer of moss or the rougher parts of the compost, and then put in 3 inches of soil, consisting of two parts sandy loam, one part leaf soil, and one part of sand, mixed together, and cover with an inch thick of sand. You may then put in the cuttings about 1½ inch apart, give a gentle watering, and set the box out of doors in the full sun. You need not cover with the glass, as the cuttings will not be so liable to damp off without it, and they may remain out of doors until the weather becomes frosty at the end of October or beginning of November; then remove them to a light, airy window. Take off the dead leaves as they appear. We conclude your plants are the common bedding sorts. If you mean the tender kinds, the box should be placed in the window at once, and be covered with the glass, admitting a little air every morning for a short time, so as to give a change of air and prevent damp. No more water ought to be given than is sufficient to keep the soil moist. In a month the plants will do best without the glass. Pot them off next March, keeping them dry through the winter.

CYANOPHYLLUM MAGNIFICUM TREATMENT (*W. A.*).—The plant is an evergreen. The shrivelling and falling of the leaves is owing to a sudden change of temperature, probably from cold. During the winter no more water should be given than will keep the soil just moist and the foliage fresh; indeed, the plant ought to be kept dry, not causing the leaves to fall or the wood to shrivel. A temperature of 55° or 60° at night is suitable until February, when an increase of temperature should be given, and it may be gradually raised to 60° or 65° at night, 70° to 75° by day without sun, and 80° to 85° with sun and abundance of air. A moist atmosphere should be maintained by frequently sprinkling the paths, stages, walls, &c., but avoid wetting the foliage, and slight shade ought to be afforded from bright sun. The plant should have abundance of room, and light on all sides, so as to keep it from growing unequally. Pot it in March or April when growth commences, using a compost of four parts fibrous loam, two parts leaf mould, two parts sandy peat, one part old cow dung, one part charcoal, in lumps from the size of a pea to a hazel nut, and one part silver sand, the whole well mixed. Do not sift the compost, but tear it in pieces, and make rather fine, affording extra drainage.

SILENE PENDULA PLANTING (*Sunny*).—The plants may be put into the beds where they are to bloom when the bedding plants are removed; but if that cannot be done until the season is advanced, say November, the ground being then cold and wet planting should be deferred until March. In the latter case the plants should be planted out in reserve beds in open yet sheltered positions, and in sandy loam enriched with leaf mould. Take them up with good balls early in March, and plant them where they are to flower, watering at planting and in dry weather. The plants will flower in April or May, and continue in bloom up to June. Plants from seed sown now will flower early in summer. The seeds should be sown where the plants are to bloom. The Cinerarias are very handsome shrubs, suitable for walls with southern aspects. The best of them are C. azureus, C. floribundus, C. thyrsiflorus, and C. integerrimus. They have blue, lilac, and white flowers from June to the end of summer.

FERN CASE (*W. C.*).—The globe or glass should be close-fitting, with no space between the glass and stand to admit air. The glass would be better if it had three small holes in the top, so as to allow of the plants having a change of air. Three holes, each a quarter of an inch in diameter, would be sufficient for a glass exceeding 15 inches in diameter, or one half-inch hole in the centre would answer. The glass should then only be taken off for watering. If there is no hole, the glass may be taken off occasionally and wiped dry; on alternate days in summer, and twice a-week in winter will be sufficient. Do not overwater, but keep the soil moist, and set the case in a light but not very sunny window, turning the stand round occasionally.

FERN (*D. M.*).—We cannot decide without seeing a mature frond. There are many species in the genus Gymnogramma. Yours may be *G. sulphurea*.

NAMES OF FRUITS (*C. R. Scholfield*).—2, Yorkshire Greening; 3, Margalado Pippin; 5 and 7, Winter Greening; 8, Pursemouth; 9, Beurré Giffard. (*William Bishop*.—1, Syringrove Codlin; 2, Manks Codlin; 3, Hawthornden; 4, Yorkshire Greening; 5, Dunmore; 6, Bedfordshire Foundling. (*W. Ashwell*.—The Fig is the Brunswick, and the Apple the Alfriston. (*Al Fresco*).—The Grape you mention in your letter under the name of "Do la Palestine," is decidedly the same as the Syrian. White Nice, which is also sometimes, but very erroneously, called Syrian, is quite distinct, and it is possible that the Syrian you have hitherto known is White Nice. This, though producing very large bunches, never has them so large nor so long as the Syrian. All the new Grapes you have named in your letter are of first-rate quality. Mrs. Pince's and Madresfield Court are noble Grapes.

NAMES OF PLANTS (*J. S. T.*).—We have repeatedly said that we cannot name florists' varieties, nor any plants from leaves only, and you have now sent us twenty-eight leaves, all of florists' varieties! (*Sophie Webster*).—Erythrina crista-galli. (*J. R.*).—The larger flower is the Althæa frutex, Hibiscus syriacus; the smaller flower Leschenaultia formosa.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending September 21st.

POULTRY, BEE, AND PIGEON CHRONICLE.

A POULTRY SHOW FOR LONDON.

I TRUST "AN AMATEUR" will meet with a liberal response to his proposal for a London poultry show. Why should not the largest city in the world be able to have what most towns in the north of England have year after year? I think it is because the meetings that have taken place have not been sufficiently central, and made known to the principal breeders by advertisement or otherwise. There is, I am convinced, in London the material for a respectable show. I have five poultry breeders among my own circle of friends who, I doubt not, would contribute to such an exhibition. What I would suggest is, that a committee be appointed to organise the proceedings, and the time and place of the show. My proposal is to ascertain if the new room at the Agricultural Hall could be hired for the same time as the Cattle Show. If this could be obtained, the poultry show would most likely pay expenses, as it would be a great temptation for our country cousins to see, on account of its being on the same spot as the chief attraction then in London. If a few known breeders will only come forward and amateurs lend a hand, there is not much fear but what we could have what we desire—namely, a creditable and profitable London poultry show. I will do my part by giving a guinea towards expenses, and a guinea towards a silver cup for the best pen in the show, and will also exhibit a pen of birds. Will a few more make a start by doing the same?—GEORGE HASTILOW, 53, *Walford Road, Stoke Newington, N.*

MIDDLETON POULTRY SHOW.

IT is to be regretted a Show so well supported, and at the same time one in which the competition was so good as that held at Middleton on the 16th inst., should not last more than a single day, and it is probable, were proper provision made, an increased revenue would result from an extension of the time of the Show. It is one of the most popular meetings of the day, and certainly with a little extra provision against weather it might be made one of the first shows of poultry. Black Reds were unquestionably as a whole the best of the *Game* classes, and some excellent specimens were on exhibition. Buffs, White, and Partridge-coloured *Cochins* were in strong force. *Hamburghs* were good, the Spangled varieties and the Black especially so. *Polands* were also capital, and the *Pigeons* were most meritorious. If any further arrangement for the protection of the poultry from bad weather could be devised, without making too great a call on the funds of the Society, it would be expedient to do so.

(*From a Correspondent.*)

THE Rabbits in most classes mustered strongly. Five classes were wisely given for distinct varieties, not of colour, as is the case at some shows, especially amongst the Lops, and then, perhaps, leaving one class only for the other beautiful varieties. In the five classes each animal could be compared with one of its own kind, which is the only mode to enable the Judges to award honestly the prizes. The entry fee was a tenth of the prize, being to my mind a fair amount. Large entry fees too often defeat their object, and prove a barrier to many specimens being sent.

Some good Lop-eared specimens were shown, and the beautiful doe belonging to Mr. Easten justly deserved the first position she obtained. The Angoras were good, well wooled, but rather small. Some of the Himalayans I think deserved a more honourable position, if size and blackness of the extremities are the test, as in my opinion they should be. The most perfect in the silver shade amongst the Silver-Greys,

I think, were returned to their owners minus certain cards of distinction, to which they were honestly entitled. In the "Any other variety" class I missed some fine specimens of the Patagonian and Belgian Hare Rabbit exhibited last year, and which enabled Middleton to say that at that Show the whole Rabbit family was fully represented. The pretty little Dutch specimens of Mr. Hudson I think deserved the position they took. Might I suggest to the Committee a little more attention to the creature comforts of the specimens, remembering that some of them had travelled a great distance to the Show, and had to return, I suppose, the same distance? The pens were roomy and well protected from the weather, which cannot be said of all shows.

GAME (Black-breasted and other Reds).—*Cockerel and Pullet.*—1 and Cup, C. Chaloner, Whitwell, Chesterfield. 2, J. Wood, Wigan. 3, H. Jowett, Idle, Leeds. *hc*, T. Statter, jun., Stand Hall, near Manchester; E. Mann, Walfield, Stand, Manchester. *Cockerel.*—1 and Cup, T. Dyson, Halifax. 2, T. Statter, jun. 3, J. H. Smith, Plainville, York. *hc*, T. Statter, jun.; Master W. Fletcher, Stonecliough, Manchester; Capt. Grove Price, Tayntoo. *c*, J. H. Wilson, St. Bees. *Cockerel or Pullet.*—1, C. Chaloner. 2, J. Halsall, Ince, Wigan. 3, T. Dyson. *c*, Master W. Fletcher.

GAME (Any other variety).—*Cockerel.*—1, C. Chaloner. 2, T. Dyson. *hc*, J. Halsall. *Pullets.*—1 and Cup, J. Wood, Wigan. 2, J. Holland, Manchester. 3, J. H. Wilson. 4, P. Norbury, Bowdon (Black Red). *hc*, S. Matthew, Stowmarket; P. Norbury (Piles); Master W. Fletcher; R. Payne, Brierfield, Burnley (Brown Reds); C. W. Brierley, Middleton.

GAME (Any breed).—*Adults.*—1, C. W. Brierley. 2, J. Wood. 3, C. Chaloner.

SPANISH.—*Cockerel and Pullets.*—1 and Cup, E. Jones, Clifton, Bristol. 2, W. & F. Pickard, Thorner, Leeds. 3, F. & C. Haworth, Newfield, Haslingden. *Cockerel.*—1, H. Beldon, Goitstock, Bingley. 2, T. & E. Comber, Myddleton Hall, Warrington. *Pullets.*—1, E. Jones. 2, T. & E. Comber.

DORKINGS.—*Cockerel and Pullets.*—1 and Cup, T. E. Kell, Wetherby. 2, T. Statter, jun. 3, Miss E. Whittington, Preston Hill, Henley-in-Arden. *c*, J. White, Warlaby, Northallerton. *Cockerel.*—1, J. Martin, Claines, Worcester. 2, E. Leech, Rochdale. *hc*, Rev. J. F. Newton, Kirby-in-Cleveland; S. H. Stott, Rochdale. *Pullets.*—1, N. G. Russel, Womaston Court, Kingston, Herefordshire. 2, J. Martin. *hc*, Rev. J. F. Newton; J. White; N. G. Russell; E. Leech; E. Shaw, Plas Wilmot, Oswestry.

BRAHMA POOTRA.—*Cockerel and Pullets.*—1, Cup, and 2, Rev. E. Alder, Etwall Vicarage, Derby. 3, T. A. Dean, Moreton-on-Lngg. *c*, H. Dowsett, Pleshey, Chelmsford, Essex; C. Leyland, Morris Brook, Warrington; E. Leech. *Cockerel.*—1 and 2, Rev. E. Alder. *c*, Dr. Holmes, Chesterfield. *Pullets.*—1 and 2, Rev. E. Alder. *hc*, T. A. Dean.

COCHIN-CHINA (Buff and Cinnamon).—*Cockerel and Pullets.*—1, C. Sidgwick, Ryddlesden Hall, Keighley. 2, W. A. Taylor, Manchester. 3, D. Young, Leamington. *Cockerel.*—1, C. Sidgwick. 2, W. A. Taylor, Manchester. *hc*, W. A. Taylor; Mrs. Allsopp, Hindlep Hall, Worcester. *c*, J. Holden, Moston, near Manchester. *Pullets.*—1, J. Sichel, Timperley. 2, W. A. Taylor. *hc*, C. Sidgwick; W. A. Burnell, Southwell, Notts; C. Banbery, Wolverhampton; Mrs. Allsopp; Bowman & Fearon, Whitehaven.

COCHIN-CHINA (Any other variety).—*Cockerel and Pullets.*—1 and Cup, C. Sidgwick. 2, A. Williamson, Queniborough, Leicester. 3, T. Stretch, Ormskirk. *hc*, W. A. Taylor. *Cockerel.*—1, C. Sidgwick. 2, A. Williamson. *c*, A. P. Steedsman, Broomegrove, Worcestershire. *Pullets.*—1, C. Sidgwick. 2, W. A. Taylor.

HAMBURGHS (Golden-pencilled).—*Cockerel and Pullets.*—1, H. Beldon. 2, W. R. Park, Abbotsmeadow, Melrose, N.B. 3, T. Wrigley, jun., Tonge Hall, Middleton. *c*, H. Pickles, jun., Earby. *Cockerel.*—1, R. R. Parker, Ipswich. 2, W. Bearpark, Ainderby. *hc*, T. Wrigley, sen., Tonge Hall. *Pullets.*—1, W. Speakman, Doddington Park, Nantwich, Cheshire. 2, F. H. Taylor, Middleton. *c*, J. Wrigley.

HAMBURGHS (Silver-pencilled).—*Cockerel and Pullets.*—1, H. Beldon. 2, H. Pickles, jun. 3, J. Lee, Middleton. *c*, F. & C. Haworth, Newfield. *Cockerel.*—1, Mrs Allsopp. 2, H. Pickles, jun. *Pullets.*—1, A. Woods, Seftoe, Liverpool. 2, Ashton & Booth, Broadbottom, Mottram.

HAMBURGHS (Golden-spangled).—*Cockerel and Pullets.*—1, J. Buckley, Taunton, Ashton-under-Lyne. 2, J. Ogden, Denton Lane, Chadderton. 3, E. Brierley, Haywood. *hc*, J. Lee, Middleton. *c*, N. Marlor, Denton, Manchester; E. Brierley. *Cockerel.*—1, W. Swire, Thwaites Bank, Keighley. 2, T. May, Wolverhampton. *Pullets.*—1, T. May. 2, J. Andrew, Waterhouses, Ashton. *c*, E. Brierley.

HAMBURGHS (Silver-spangled).—*Cockerel and Pullets.*—1, J. Fielding, Newchurch, Manchester. 2, W. Bairstow, Fearncliffe, Bingley. 3, H. Beldon. *Cockerel.*—1, J. Fielding. 2, W. A. Taylor. *hc*, Ashton & Booth. *Pullets.*—1, J. Fielding. 2, Ashton & Booth. *hc*, J. Partington, Little Heaton, Middleton; W. Bairstow, Fearncliff, Bingley.

HAMBURGHS (Black).—*Cockerel and Pullets.*—1 and Cup, C. Sidgwick. 2, Mason & Walker, Denton, Manchester. 3, Rev. W. Sergeantson, Acton Burnell. *c*, Walker & Wood, Slaithwaite. *Cockerel.*—1, Mason & Walker. 2, C. Sidgwick. *c*, J. Holt, Little Green, Middleton. *Pullets.*—1, Mason and Walker. 2, J. M. Kilvert, Ludlow. *hc*, A. E. Hanson, Castleton, Heywood; Mason & Walker; Hoyle & Patrick, Trough Syke, Bacup; H. Bagshaw, Uttoxeter.

FRENCH FOWLS.—*Cockerel and Pullets.*—1, Hon. H. W. Fitzwilliam, Wentworth Woodhouse (Crève-Cœurs). 2, R. B. Wood, Uttoxeter, Staffordshire. 3, W. O. Quibell, Newark. *hc*, W. O. Quibel; Mrs. Mc'Adam, Woodfield, Upper Banchory, Aberdeen (Houdans); Hon. H. W. Fitzwilliam (La Flèche). *c*, Mrs. Wilkin, Bootle Rectory, Cumberland (Crève-Cœur). *Cockerel.*—1, S. H. Stott, Rochdale. 2, W. O. Quibell. *Pullets.*—1, W. O. Quibell. 2, R. Wiley, Tettenhall. *hc*, C. Layland, Morris Brook, Warrington; R. B. Wood, Woodland Hall, Uttoxeter.

ANY OTHER VARIETY (Not included in the classes).—*Cockerel and Pullets.*—1, Cup, and 2, H. Beldon, Yorkshire. 3, W. Gamon, Hoole Cottage, Chester. *Cockerel.*—1, H. Beldon. 2, J. Partington, Bury Lane, Leigh. *Pullets.*—1, H. Beldon. 2, J. Partington. *hc*, W. Gamon.

GAME BANTAMS.—1 and Cup, Ingleton, Farnsfield, Notts. 2, W. F. Entwisle, Leeds. 3, W. Shamadia, Southwell, Notts. *hc*, J. Crosland, jun., Wakefield. *Chickens.*—1, Cup, and 2, J. Crosland, jun. 2, Harwood and Buckley, Accrington. *hc*, J. H. Ince, Wigan; T. Sharples, Rawtenstall; J. Eaton, Vine Cottage, Farnsfield, Notts; W. Hasltroell, Whitehaven.

BANTAMS (Any other variety).—1, W. A. Taylor. 2, S. & R. Ashton, Mottram. 3, S. H. Stott, Rochdale (Japanese).

SELLING CLASS.—1, M. Cavanagh, Shaw Clough, Rochdale. 2, A. Bamford, Peach Bank, Tonge, Middleton. 3, J. Horrocks, Tonge, Middleton. *hc*, D. Bamford, Harpurhey (Buff Cochins). *Chickens.*—1, A. Bamford. 2, W. A. Burnell, Winkburn Hall, Southwell, Notts. *hc*, W. A. Burnell; F. & C. Haworth.

DUCKLINGS (Aylesbury).—1 and 3, Mrs. Seamons, Hartwell, Aylesbury. 2, E. Leech.

DUCKLINGS (Rouen).—1 and Cup, E. Leech, Greave House, Rochdale. 2, W. Gamon. 3, J. Wright, Melton Mowbray. *hc*, J. F. Bott, Cammas Hall, Morrell Reading; T. Statter, jun; W. Gamon; L. Patton, Hillmore, Bishop's Hill, Taunton; S. H. Stott, Rochdale.

DUCKLINGS (Any other variety).—1 and 3, C. W. Brierley, Middleton 2, T. Statter, jun.

GOSLINGS.—1, S. H. Stott. 2, Rev. G. Hastler, Stillingfleet Vicarage, York. *hc*, T. Statter, jun; E. Leech; S. H. Stott.

TURKEYS.—1, E. Leech. 2, Mrs. A. Guy, Eaton, Grantham.

PIGEONS.

TUMBLERS (Almond).—1, *hc*, and *c*, R. Fulton, Deptford. 2, J. Fielding, jun., Rochdale.

TUMBLERS (Any other variety).—1 and 2, R. Fulton (Mottles). *hc*, R. Fulton; J. Fielding, jun.

BALDS OR BEARDS.—1, J. Fielding, jun. 2, T. Newell, Ashton-under-Lyne.

CARRIERS.—*Cock.*—1, E. Horner, Harewood, Leeds. 2, R. Fulton. *hc*, R. Fulton; J. Chadwick, Bolton. *c*, W. R. & H. O. Blenkinsop, Newcastle-on-Tyne. *Hen.*—1 and 2, R. Fulton. *hc*, E. Walker, Leicester.

POUTERS.—*Cock.*—1 and 2, R. Fulton. *hc*, E. Horner. *Hen.*—1, E. Horner. 2, R. Fulton. *hc*, R. Fulton; E. Horner. *c*, W. Gamon, Chester; W. B. Tegetmeier, Finchley.

BARBS.—1, Cup, and 2, Capt. Heaton, Eccles. *hc*, J. Fielding, jun. *c*, E. Horner.

TURBITS.—1, J. Fielding, jun. 2 and *hc*, R. Wilson, Thirsk. *c*, R. Fulton.

JACOBINS.—1, J. Hall, Blackley. 2, R. Fulton. *hc*, E. Horner.

FANTAILS.—1, E. Horner. 2, W. H. Tomlinson, Newark. *hc*, H. Yardley, Birmingham; T. H. Frean, Liverpool.

OWLS.—1 and *hc*, J. Fielding, jun. 2, F. Graham. *c*, Countess of Derby, Knowsley.

NUNS.—1, F. Graham. 2, H. Yardley.

DRAGOONS.—1 and 2, T. H. Frean. *hc*, R. Marshall, Lower Broughton; E. Horner. *c*, H. Yardley.

TRUMPETERS.—1, E. Horner. 2, W. Gamon.

ANY OTHER VARIETY.—1, W. B. Tegetmeier. 2, H. Yardley. *hc*, E. Horner; J. Watts, King's Heath, Birmingham. *c*, G. H. Withington, Kersal Hill, Manchester (Silver-coloured Roman Runts); H. Yardley.

SELLING CLASS—1, E. Walker, Leicester. 2, T. H. Frean (Magpies). *hc*, J. Fielding jun. *c*, W. MacLaren, Highfield, Pendlebury, Manchester; T. H. Frean; F. Key, Beverley; J. Watts.

RABBITS.—*Lop-eared.*—1, A. H. Easten, Hull. 2, J. T. Sykes, Rochdale. *hc*, G. Hopley, Manchester. *Angora.*—1, W. J. Butterworth, Stonyfield, Rochdale. 2, T. Wild, Heywood. *Himalayan.*—1, A. L. Rawstron, Haslingden. 2, W. J. Butterworth. *Silver-Grey.*—1, E. E. M. Royds, Rochdale. 2, S. G. Hudson, Hull. *Any other Variety.*—1 and 2, S. G. Hudson. *Selling Class.*—1, E. Higham, Middleton. 2, W. J. Butterworth.

The Judges were Messrs. Hindson and Teebay for Game, Waterfowl, &c.; Messrs. Hewitt and Tegetmeier for other classes of poultry; and Mr. Esquilant for Pigeons and Rabbits.

DERBY POULTRY SHOW.

IT has always been a somewhat remarkable feature of the Derby Poultry Shows, that those classes in which the competition was most severe at one year's show, had almost invariably a slight entry in the following year. It was again so this year, *Spanish* and Aylesbury *Ducks* being the classes in which there was least competition; in fact, both were quite indifferent in quality. The Grey *Dorkings*, Dark *Brahmas*, Rouen *Ducks*, *Geese*, and *Turkeys*, have rarely been equalled at any previous Derby Show, as at present restricted. Many of the *Hamburghs* were of first-rate character, and the White *Cochins* were, undoubtedly, one of the greatest features of the show tent. The *Pigeons* were of excellent quality, and were well represented. Few shows have proved themselves throughout so good. Occasional heavy showers were a great drawback to a large attendance. The Committee were most untiring, and the provision for the poultry, &c., was excellent.

DORKINGS (Coloured).—1 and 2, Mrs Arkwright, Etwall Hall, Derby. *hc*, Countess of Chesterfield.

DORKINGS (White).—, J. Faulkner, Bretby. 2, W. R. Dick, Ticknall.

SPANISH.—1, Withheld. 2, W. Cox, Brailsford.

GAME (Dark-breasted).—1, Rev. T. C. O'Grady, Hognaston Vicarage. 2, J. Bakewell, Draycott Mills. *hc*, W. Cox. *c*, C. Minors, Sudbury; J. Faulkner.

GAME (White or Pile).—1, C. Spencer, Thulston. 2, E. Canner, Stanley Grange.

HAMBURGHS.—*Golden-pencilled.*—1, G. J. Mitchell, Newton Mount. 2, J. Bakewell. *Golden-spangled.*—1, J. Bakewell. 2, C. Mellor, Atlow. *Silver-pencilled.*—1, J. Bakewell. 2, H. King, Melbourne. *Silver-spangled.*—1, J. Bakewell. 2, C. Pickering, Kirk Langley

COCHIN-CHINAS.—1 and 2, A. O. Worthington, Newton Park, Burton-on-Trent.

BRAHMAS (Light).—1 and 2, A. O. Worthington.

BRAHMAS (Dark).—1 and 2, Rev. E. Alder, Etwall, Derby. *hc*, Rev. E. Alder; A. F. Hurt, Alderwasley.

CROSS-BRED FOWLS.—1, J. Faulkner. 2, G. J. Mitchell.

DUCKS (Rouen).—1, J. Bakewell. 2 and *hc*, A. O. Worthington.

DUCKS (Aylesbury).—1, Withheld. 2, Miss S. Hurt, Chase Cliffe.

GEESE.—1, W. Cox. 2, J. Faulkner. *hc*, A. O. Worthington.

TURKEYS.—1, A. O. Worthington. 2, A. M. Mundy, Shipley Hall. *hc*, J. G. Mitchell.

SPECIAL PRIZE.—1, Mrs. Arkwright (Dorkings) 2, J. Bakewell (Geese).

EXTRA.—*hc*, Lord Manchline Donington Park (Bantam and pair of Greys).

PIGEONS.—*Rock or Dovecote.*—1, J. Faulkner. 2, F. Sale, Derby. *Antwerp or Belgians.*—1, Mrs. Arkwright. 2, F. Sale. *hc*, J. Langley,

Mickleover. *Tumblers.*—1 and 2, F. Salo. *Fantails.*—1, F. Salo. 2, W. R. Dick, Ticknall. *hc*, A. O. Worthington; F. Salo. *Any other Distinct Variety.*—1, 2, and *c*, F. Salo (Trumpeters, Magpies, and English Owls). *hc*, J. Harpur, Derby (Dragoons); O. Haywood, Derby (Barbs).

Mr. Drewry, of Burton; Mr. Hewitt, of Birmingham; and Mr. Lowe, of Comberford, were the Judges.

WHITBY CANARY SHOW.

This Exhibition of British and foreign cage and song birds was held in connection with the thirtieth annual Exhibition of the Floral and Horticultural Society in the Congress Hall, on Tuesday, the 14th inst.

I am pleased to be able to give a detailed report of it, for, like those gentlemen who have for the past week or two been upholding the dignity of their hobby—the fancy Rabbit, I, too, am jealous, very jealous, of my pet fancy—the Canary, and I don't like to see him consigned to the fag end of a report. I sympathise very sincerely with the writers to whom I refer, but I would just ask them whether the neglect they complain of is not to some extent their own fault? Do they do all in their power to raise their fancy to its proper level? and are the beauties of the fancy Rabbit, as developed by them, brought sufficiently before the million through the powerful agency of the press? I am sure the pages of "our Journal" are open to the lovers of all domestic pets. We have even had an enthusiastic writer on Ferrets! Why not, then, write up your favourites? I, for one, would much like to see a series of practical papers on the modern fancy Rabbit, its varieties, &c., with details as to points and management. I have always had a sneaking kindness for Rabbits, and who has not? My boys do a large stroke of business in the line, the balance always being on the wrong side. Rest assured of this, that if you love your pets and work for them, you will give untold pleasure to many a reader, and the work will be a labour of love, repaying itself a thousandfold. Make up your minds that Rabbits shall not be consigned to the last half dozen lines of a report, and you will soon find them at the other end.

But, "*revenons à nos moutons.*" I was obliged to make an early start to reach Whitby in good time, and 5.10 A.M. saw me *en route*. Nearly all my fellow-travellers in the early stage of the journey were butchers or drovers, redolent of suet, bound for Newcastle cattle market. The conversation, however, took quite a literary turn, having reference chiefly to Pretender and Harriet Beecher Stowe. While changing at Ferry Hill for Stockton, I witnessed a very touching incident, now frequently to be seen in this district. A small group of men and women, waiting the arrival of the up train, were hanging on one another's necks, giving utterance to such expressions of grief as one could hardly listen to without emotion. The good-bye scene was most affecting; I cannot describe it. A bystander gave me the clue to the whole in one word—America. It was a small family leaving, most probably, their native village to seek a home across the Atlantic. God speed them in their journey to the Far West!

Stockton was hardly astir when we ran into the station, at least the refreshment-room was scarcely awake, the young lady in charge telling me I could have no coffee, as "t'kettle wasn't boiling," and as "t'kettle" refused to boil in anything like a reasonable time, I went my way minus my coffee. From Stockton to Whitby the scenery is very romantic, the line following the windings of the Esk through the tortuous passes of the Cleveland Hills, crossing and recrossing the river a score of times, bounded on either side now by overhanging woods, and now by wide moors, covered as far as the eye could reach with blooming heather. Far up on a hillside a column of smoke indicated the spot where, I was told, a jet mine had taken fire. The stations are some of them beautifully situated, but some in apparently the most out-of-the-way places, within sight of no human habitation. I was informed at all of them that "Bryant & May's matches would light only on the box;" and at one, where there seemed to be only a solitary station-master and porter rolled into one, some enterprising tailor announced that he was prepared to make trousers at 16*s.* 6*d.* a-pair. The match business seemed to thrive all through the district, but the tailor gave up in despair further on, where there seemed no legs to clothe, even at the ruinous figure of 8*s.* 3*d.* per leg, the only inhabitants being a few black-faced sheep, who popped their heads above the heather to stare at us as we rushed past.

Arrived at Whitby, I was soon among the birds with my co-adjutor, Mr. Allenby, of Durham. They were arranged on either side of the Hall, the horticultural department occupying the centre, producing a very charming effect. The Derby and Northampton schools, as will be seen by the prize list, were strongly represented by Mr. J. Bexson and Messrs. Moore and Wynn, who exhibited some very fine specimens. In condition, the primary point, they could not be excelled, taking into consideration the early stage of the season. Both are evidently in "form" this season, and "will be heard of to advantage" at future shows. The prize birds in Clear Yellows and Clear Buffs stood far out above their fellows, though the specimens "mentioned" were all creditable birds. In Class 4, Buff Norwich, Moore & Wynn were first and second with two lovely birds, which will take some beating wherever they go. Class 5, Yellow Norwich, a very interesting class, since it comprises the "*crême de la crême*" of quality, and one which should be in every schedule offering prizes for Norwich birds, contained some glorious specimens. No. 52, first prize, J. Bexson, was a beauty, while 57, second prize, Moore & Wynn, a bird of a directly opposite character, was gorgeous in its colour. The former was almost absolutely clean, the latter very heavily marked—fitting representatives of a class hitherto excluded from our shows. Class 6 was also well represented. The Belgians were inferior, and Classes 9 and 10, with the exception of the winning birds, were of no character whatever. Mr. Bexson was first in Cinnamons, Yellow and Buff, beating the veterans Moore & Wynn, though the second prize went to Northampton through Mr. Irons. Lizards were inferior, and in Class 14, Silver-spangled, a Mr. J. Stevens, of Middlesbrough, exhibited a most palpably stained specimen. I wish all societies would banish such offenders, and so stamp out the disease. Refuse their entries, disown them, turn them out of the society of gentlemen to mate with their own kind, and do not even grant a ticket of leave for many a year. In Class 16, "Any other variety," the first prize went to Mr. Calvert, of York, for the best Crested Norwich bird I ever saw, excepting that shown by Mr. Young at the Crystal Palace last February, and in some respects he was superior even to that wonder. No. 157, second prize, Mr. G. Gayton, Northampton, was a splendid Crested bird, and 153, third prize, fell to Moore and Wynn for a very neatly marked Cinnamon. No. 154, Mr. E. Mills, Sunderland, was very neat, handsomely crested, of good quality, but rather small. Among the Mules there were some grand specimens exhibited by Mr. J. Young and Mr. George Shiel, of Sunderland, who divided the honours between them; Mr. Hawman, of Middlesbrough, being very highly commended in the Buff-variegated class for a bird of extraordinary merit.

In the Variegated Yellow class the contest was very close, though lying between two birds of widely different character, the one a finely six-marked bird, but backward in condition, the other heavily marked with marvellous exactness, and in the bloom of perfect condition, and it was not till a jury was empanelled that the first prize was awarded to the lighter-marked bird—a judgment from which I dissent, since I hold perfection of condition to be a primary point, not to the exclusion of all others certainly; but I maintain that a half or three-parts moulted bird, and not very clean either, must, indeed, be a veritable wonder to displace a high-class bird in faultless trim. It is not for a judge to determine what any bird *might be made* in a month, but to say what he *is* on the day of show when measured by the standard of the schedule, according to the conditions of which the bird is shown—viz., "for beauty of plumage and high condition." I am happy to say that the respective owners of the birds endorsed my judgment.

Excepting a very fine dark Mule, first prize, in Class 20, with a wonderful "flourish," there was not much else worth notice, except the Parrots, the first prize for which was won by Mrs. Wilkinson, the amiable lady of the indefatigable Honorary Secretary. Of the flower show I can say but little, it is not so much in my line; but I was assured by competent judges that it was the best ever held in Whitby. Of the arrangements it is impossible to speak too highly. Everything was conducted as it should be; in fact, it is a model Show in this respect. The Secretary is the right man in the right place, and with a somewhat amended schedule he will make the Whitby Show one of the best in England.—W. A. Blakston.

The following is the prize list:—

Norwich (Yellow).—1 and 2, Moore & Wynn, Northampton. *vhc*, R. Simpson, Whitby. *hc*, E. Mills, Sunderland. *c*, J. Bexson, Derby.

Norwich (Buff).—1 and 2, J. Bexson. *vhc* and *hc*, Moore & Wynn.

Norwich (Yellow, evenly marked).—1, J. Bexson. 2, G. Gayton. *vhc*, Moore & Wynn. *hc*, T. Irons.

NORWICH (Buff, evenly marked).—1 and 2, Moore & Wynn. *vhc*, T. Irons. *hc*, G. Shiel.

NORWICH (Yellow, unevenly marked or ticked).—1 and *c*, J. Bexson. 2, Moore & Wynn. *vhc*, Pennock & Blackstone. *hc*, R. Hawman, Middlesbrough.

NORWICH (Buff, unevenly marked or ticked).—1, J. Bexson. 2, G. Gayton. *vhc*, T. Irons; R. Simpson. *hc*, Pennock & Blackstone. *c*, Moore & Wynne.

BELGIAN (Yellow).—1, J. Bexson. 2, Allan & Baines, York.

BELGIAN (Buff).—1, W. Parritt, Rnswarp. 2, F. Fritschler.

YORKSHIRE (Yellow).—1, R. Hawman. 2, G. Garbutt. *vhc*, W. Handel, Whitby. *hc*, Mrs. J. Wilkinson.

YORKSHIRE (Buff).—1 and *hc*, J. Gray. 2, W. Winter.

CINNAMON (Yellow).—1, J. Bexson. 2, T. Irons. *vhc*, G. Gayton.

CINNAMON (Buff).—1, J. Bexson. 2, T. Irons. *vhc*, Moore & Wynn. *hc*, R. Hawman.

LIZARD (Golden-spangled).—1, Withheld. 2, E. Barker.

LIZARD (Silver-spangled).—1, R. Hawman. 2, E. Barker.

CANARY (Green).—1, T. Irons. 2, Allan & Baines.

ANY OTHER VARIETY.—1, J. Calvert, York. 2, G. Gayton. 3, Moore and Wynn. *vhc*, G. Shiel; E. Mills. *hc*, J. Young (Crested); T. Armstrong.

SIX YOUNG BIRDS IN ONE CAGE.—1, J. Calvert. 2, R. Simpson. *hc*, M. Thompson, Whitby. *c*, T. Armstrong.

GOLDFINCH MULE (Yellow marked).—1, J. Yonng. 2, G. Shiel.

GOLDFINCH MULE (Buff marked).—1, J. Yonng. 2 and Extra 2, G. Shiel. *vhc*, R. Hawman. *hc*, Allan & Baines.

GOLDFINCH MULE (Dark).—1, Allan & Baines. 2, Moore & Wynn.

BULLFINCH.—1, M. Millington, York. 2, J. Howe.

LINNET.—1, J. Calvert. 2 and *vhc*, T. Philpot. *hc*, McLachlin & Brown.

PARROT.—1, Mrs. J. Wilkinson. 2, J. Calvert.

PARAKEET.—1, G. T. Knaggs, Esplanade.

DISTRICT PRIZES.

CANARY.—*Clear.*—1, Pennock & Blackstone. 2, E. Barker. *Marked.*—1, W. Raw. 2, E. Barker. *vhc*, W. Elders. *hc*, W. Stevens. *c*, J. Readman. *Crested.*—1, Pennock & Blackstone. 2, R. Simpson. *vhc*, W. Elders. *hc*, J. Hart. *Half-bred Belgian.*—1, J. Waters, Whitby. 2, T. Masterman, Longsteps. *Mule.*—1, R. Simpson. 2, R. Corner, Whitby.

RABBITS AND THEIR JUDGES.

THE letter by "HIMALAYAN," under the above heading, in your number of September 2nd, is admirable in every respect, and I venture to say that hundreds of your readers in the Rabbit fancy have thanked him in their hearts for so ably taking up the Rabbit-right question. Indeed, no one, whether personally interested in the fancy or not, will deny that the Rabbit section in a show is more frequently than not judged by men who are conscientious, and thoroughly up in the other departments, but who will frankly admit that they are placed in a false position when called upon to deal with Rabbits. They come to this enforced part of their work tired out with their previous labours; their heart is not in it; they have either no confidence in themselves, or sadly too much; they poke a Lop-eared Rabbit with their stick as they would a pig or a Game bird, to see its properties, and if they have ever heard of such a thing as measuring, they have to ask somebody whether it is the ear or the tail that Rabbit folks think such a deal about. If it is replied that it would not pay to have a special judge for Rabbits, I ask, How often has it been tried? and I echo the words of "HIMALAYAN," "the expense would soon be more than compensated by the increased number of entries which would be obtained when it was known that a competent judge was to award the prizes."

To prove the correctness of this view, I would adduce the Hull Show as an illustration. They very wisely, as I thought, printed the Judges' names in conspicuous type on the schedule, and the well-known name of Mr. Millington, of York, being down for the Rabbit section, it brought no less than eighty-five Rabbits from all parts of England, and while there was a loss in nearly every department, this one more than paid. I venture the opinion that there would not have been half so many if there had been the usual uncertainty about the judge.

Again, I concur with "HIMALAYAN" in thinking "that competent men might be found within twenty miles of each large show." Here let me give an illustration. Within seven miles of the large town where I live there are two very fashionably attended poultry and flower shows every year, where Rabbits are exhibited, and yet, would it be believed? the Committees year after year ask some poultry man to go over and judge all the live stock, when there are at least half a dozen good and reliable judges of Rabbits within seven miles, who would go for their mere railway fare, considering the compliment a sufficient reward for their work. We could easily send them five-and-twenty entries, and most certainly should do so, from the place being so handy for us, but the judgment is generally so ludicrous, that those who have the very best Rabbits will not hazard the reputation of their pets by showing at all. And then we hear that it is not worth their while being at the expense of an extra man! This is a type of many larger shows, and I know some gentlemen who have first-class specimens, who simply keep them at home for their own amusement, because they will not run the double risk of bad judgment and bad treatment.

This word "risk" brings me to another point, on which I feel deeply as a lover of Rabbits, and I would ask to be allowed to give another illustration, as showing that they are treated, as "HIMALAYAN" says, "in a sort of anything-will-do-for-them manner." Myself and a few friends ran over by excursion train the other day to the Whitby Show, arriving about eleven. The sun was intensely powerful, but at times during the day it looked likely to rain, and some predicted a thundershower. We made for a part of the field where we saw some live stock under a covering of calico, but finding that they were all two-legged, we asked with great interest, Where are the Rabbits? To our amazement we were directed to a number of perfectly open wire pens, raised upon some planks, without the least pretence of any protection from heat, cold, or rain; and yet who does not know that Rabbits catch certain diseases from exposure to sun, and that they have to be kept with equal care from cold or wet? With a humane intent we respectfully asked an official how this was, as the schedule had most distinctly stated, "The Rabbits will be shown under cover." He very respectfully answered that he was guilty in one sense, but not in another, for he could assure us he himself had bought up every yard of calico in Whitby, but that, unfortunately, it had only been sufficient to cover the poultry, and that he could not obtain more in the town either for love or money! Of course we took this for a joke, and began to laugh; but in the most gentlemanly, and evidently sincere manner, he reiterated the statement, which was confirmed by the Secretary, who was standing by; both very sorry, of course. I could only exclaim, "Poor Rabbits, always last thought of!" Yet I know for a fact, that one of these exposed Rabbits was claimed at ten guineas after winning the silver cup at a recent show, and that the owner had some difficulty in persuading the buyer not to enforce his claim—but, to be sure, it was *only* a Rabbit after all! Had it been a Duck or a Goose with a fine name, there would have been the calico to protect it from sunstroke or the watery element. Well, the Judges came round, and some dozen of us were only 2 yards behind them; but our suspense was short, for they positively got through (I don't say judged) twenty-one specimens in a trifle short of two minutes! The last half minute was taken up in deciding between two Lop-eared Rabbits close together, that were much alike in size, colour, and some other points. Common sense and justice would have cried out, "Measure them if you are puzzled;" but though all their work was then done it was not worth while, and they walked off—having decided certainly, but most certainly without knowing, and as clearly not caring, which of the two best Rabbits in the Show was the better of the two. Now, I venture to affirm, without fear of contradiction from Rabbit-fanciers, that the most practised eye could not determine to half an inch the length of ear, nor the width to an inch, without measurement or opening the ear out, and yet not one Rabbit was touched except by those gentlemen's sticks.

The delighted "WINNER OF" (*two*) "SILVER-GREY PRIZES AT ROCHDALE," wonders in your last issue what we Lop-ear fanciers can find to grumble about. I have given him a nut; let him crack it.

I have only one more fault to find at present, and that is, that the pairs were put into one pen without the division that is generally made; and as we all know what these little creatures are, I call it an outrage on common decency, to say nothing of the injustice to exhibitors, who may have their pair unexpectedly spoiled by a litter before the next show. There was the same mistake at Wakefield a few days before, where two pairs were chasing round and round all the day, and I observed many a gentleman discreetly walk his lady off from an embarrassing position. I must, however, in justice say that everything else at Wakefield was admirably arranged and managed, and as to the judging, it was refreshing to many of us, who could clearly see what was going on, to observe that the Rabbits occupied their full share of attention, every Lop-eared one being taken out and measured, and evidently receiving a most careful and conscientious consideration of its claims. This is the right way to stop grumbling.—ONE OF MANY WITNESSES.

SOAP A REMEDY FOR A BEE'S STING.

SEEING from the papers recently, a sad and fatal result from an attack of bees, and for the benefit of those who may be so

unfortunate as to be similarly stung, allow me to suggest a most simple and easy remedy within reach of everyone, and in every household. Common soap, worked up into a lather on the place stung, gives immediate relief. I think if such a remedy had been applied at once in the recent fatal case, no very serious consequences would have ensued. I have tried it often, and never found it fail; it is instantaneous, easy, and clean. I sometimes when among my bees carry a small bit of soap dried in my waistcoat pocket, and if stung I just wet and rub the place; it is always sufficient.—D. H.

BUCKET HIVES.

In my little book on "Profitable Bee-keeping," recently published by the Society for the Promotion of Christian Knowledge, I recommended the use of bucket hives for cottagers. I have had one in my garden during the last twelvemonth whose dimensions are as follow:—Height, 8½ inches; diameter at the upper and broader end, 15 inches; diameter at the base where it rests on the floorboard, 12 inches, all inside measure. The hive top is a flat round board an inch thick, which projects a little beyond the rim of the hive, and merely rests upon it without any fixing.

Last August I received from Mr. Woodbury a good hybrid Italian queen, which I established in this hive at the head of a colony of common bees whose queen I had previously abstracted, the bees themselves having been driven out of a hive which stood in the same place. A few pieces of old honeycomb affixed to bars, and tied with bits of string to the under side of the moveable top of the new bucket hive were almost all the help they had. I may have given them as much as 5 lbs. of sugar syrup, not more, during the autumn and early spring. I should have given them more, but being weak in population they did not feed kindly. They managed, however, to survive the winter in good health, and began to show signs of coming prosperity as June wore on. How they contrived to live through May I cannot imagine, but by the middle of July they were glad of a small super, from which I took 6 lbs. of first-rate honeycomb a little later. This led me to hope that after all I should be able to report well on the whole of my bucket hive when the time came for the partial plunder of the hive itself, which I had all along meditated.

This time arrived last Thursday, when assisted by an enthusiastic apiarian neighbour, whom I wished to convert to my new method of cottage bee-keeping, I resolved to test the practical value of my bucket hive. First, we drove the bees into a temporary hive and put them on their accustomed stand, ascertaining beyond doubt that the queen was with them. Then with the aid of a few sulphur matches we stupefied the remaining bees in the hive, most of whom recovered afterwards and rejoined their companions. Next, after snipping the bits of twine which had secured the bars (with combs attached), to the under side of the top board, I passed a spatula beneath it all round and separated the combs below from their attachments to it. We then cut or scooped out 10-lbs. weight of the best part of the honeycomb, leaving enough for their winter supply, and not damaging the brood comb below. Only one of the ten or eleven combs became detached from the sides and was removed. All the rest were securely fastened to the sides and to the cross-stick below, and remained unchanged in position. The top board was then replaced, and after suffering the injured honeycombs within to drip into a pan, over which during the operation the hive had been placed, it was put back on its stand and the temporary hive of refuge set over it. The holes being open, the bees quickly descended, and all was soon as quiet as it had been before.

Had the honey season been more favourable, and my stock originally stronger, I doubt not I should have obtained a much larger quantity of honey; but most cottagers would be well content with a harvest of 16lbs., without destroying the hive. If necessary, I shall feed this hive in October and March next, which will, of course, somewhat diminish the profit, but a few pounds of sugar at 4*d.* per lb. are a cheap substitute for honey at 1*s.* per lb.

The following extract from "Profitable Bee-keeping," will explain the special uses of the bucket hive:—

"One of the greatest objections to the common hive is the impossibility of taking away the honey without destroying a quantity of comb, which would be of value to the bees another year—much more valuable than the wax to be got from them would be to the bee-master. Not only so; there is often an immense quantity of brood destroyed, which, if preserved, would add greatly to the prosperity of the hive another year, as these young bees will live till spring. Now, this hive with a flat and moveable top will remedy both these evils; for, after getting rid of the old bees by driving or fumigating, you may remove the top board by passing a knife with a thin blade completely under it all round, so as to separate the combs from it. Then the comb which contains the honey can be easily cut out without injuring the lower part of the combs at all, especially if there are sticks in the middle of the hive to support them. Everyone knows that the best honey is always stored by the bees in the upper part of the hive, while the queen lays her eggs in the middle and lower part of the combs. A good bee-keeper, therefore, will carefully preserve these combs and the young bees in them; for these young bees will live till spring and ought always to be saved."—B. & W.

OUR LETTER BOX.

Fowls in Confined Space (*St. Edmunds*).—We recommend you to keep Houdans, Brahmas, or Crève-Cœurs. Brahmas are very hardy, and are certainly excellent layers. They have the advantage of being good sitters and mothers if they are required in that capacity. You may well keep a cock and eight or ten pullets in such a space as you describe. We cannot recommend vendors.

Poultry Company—Defective Black Hamburgh (*M. C. C.*).—The National Poultry Company closed its establishment long since, and having died a natural death it had no successor. We never give great hopes of breeding good birds from faulty parents, and do not, therefore, approve of your scheme. The semi-white face of the Black Hamburgh cock speaks of his Spanish origin, and to mate him with a Minorca hen would be to increase the Spanish.

Incubator (*Calpe*).—We cannot recommend any. From various causes they have ceased to be patronised.

Feeding Poultry (*Amateur Poultry-keeper*).—You will lose all your chickens through bad feeding. Stock meat is a capital adjunct, but it does not yield nourishment enough to feed on; tailing wheat is bad food, and rice is worse. Your meal should be mixed only stiff enough to retain its form. Have your fowls any grass run? Discontinue the lime. We believe it is injurious if strewed on the ground, but very beneficial if used as a wash for the walls. If they have no grass, give them lettuce or green food. Chickens under two months old require chicken treatment and food—bread boiled in milk, a little chopped egg, chopped meat and bread, and beer. They should be fed away from the old birds. The latter should have barleymeal or ground oats in the morning, whole corn or Indian corn at midday, meal in the evening. Discontinue tailing wheat and rice. Give some stock meat at times for a change. (*M. S. S.*).—We disapprove of your feeding. Fowls cannot be healthy with hard crops, and their crops cannot be otherwise than hard with your feeding. Having a run of a stack-yard and field, they need only have barleymeal in the morning, barley or Indian corn at midday, and barleymeal in the evening. Buckwheat, potatoes, and Indian meal will produce the symptoms you mention. They are all bad food. Treat the chickens as we have described in the preceding answer. They must be well cared for when small, if they are not, they die as soon as they begin to make growth and feather. If you feed chickens and adults together, the latter monopolise the food and starve the former.

Game-fowl Points (*A Subscriber*).—No Game fowl should have a rose comb; such an appendage would disqualify the handsomest bird in the world. Sharp snake-like head and face, hard feather, scanty plumage, body broad between the shoulders, and tapering to the tail, perfectly straight breast-bone, are some of the principal characteristics of a good Game fowl.

Dark Brahmas' Feathers White-streaked (*J. W.*).—Is the white streak on the shaft of the feather? If it is, examine the parents closely and ascertain from which it comes, and discontinue breeding from it. It will be easy next season to put a darker cock with the hens, but we are hardly disposed to attach so much importance to the stripe as you do. It may arise from inter-breeding, but under every circumstance we should advise fresh and carefully-selected blood. We have seen where breeding-in has been followed, the pencilling intermixed with distinct white spots.

Pigeons Laying Four Eggs.—A correspondent, referring to a paragraph in last week's Journal, says that a friend of his keeps "Ponting Horsemen" Pigeons, and the hens almost invariably lay four eggs, and not at all unfrequently bring up four young ones.

Grey Colour of Honey (*S. M. I.*).—We can give no reason for the grey colour of your honey, except that we imagine it must arise from some peculiarity in the season, or in the pasture from which it has been collected.

Dogs' Meat (*J. M. B.*).—We have not the advantage of knowing a single dealer in this feed.

Dried Artichoke Bottoms (*Ignara*).—Pluck your artichokes from the stalks just before they come to their full growth, which draws out all the strings from the bottoms; boil them till you can easily take off the leaves; then lay the bottoms on this, and set them in a cool oven. Repeat this until they are dry, which you may know by holding them up against the light, when, if they are dry enough, they will appear transparent. Put them into paper bags, hang them up in a dry place, and they will keep good the greater part, if not the whole of the year.

POULTRY MARKET.—September 22.

It would be easy to dismiss our notice of the market by saying there is a small supply and a very dull trade. Partridges are plentiful, but there is a large proportion of old birds. There have been fewer Grouse than usual at this time of year. It is, perhaps, to be accounted for by the boisterous weather.

WEEKLY CALENDAR.

Day of Month	Day of Week	SEPT. 30—OCT. 6, 1869.	Average Temperature near London. Day.	Night.	Mean.	Rain in last 42 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

6	W	[and General Meeting.	61.8	43.2	52.5	22	10 6	27 5	56 6	20 6	1	11 56	279

From observations taken near London during the last forty-two years, the average day temperature of the week is 63.3°; and its night temperature 42.8°. The greatest heat was 80°, on the 5th, 1834; and the lowest cold 25°, on the 5th, 1865. The greatest fall of rain was 1.06 inch.

SEEDS versus CUTTINGS.

RAISING CENTAUREAS, VERBENAS, AND OTHER PLANTS.

AT a time when public attention is directed to the adulteration of seeds, it is not inappropriate to notice the advantage of sowing certain seeds, though not generally recognised, owing to supposed difficulties in obtaining them, and, which is of more consequence, a prejudice against sowing when other modes of propagation are available. This state of opinion by degrees works its own cure, and sooner or later the public learn to know and adopt the most suitable mode of increase, and the use of seeds instead of cuttings is the order of the day.

There are, nevertheless, certain plants thought not capable of yielding seed in sufficient quantity to meet the requirements of the public, and amongst them is one to which I would confidently call attention. Its culture has been long before the gardening community, and its propagation has been often reported as being difficult; or at all events there often seemed an impossibility to multiply it to the required extent, although others assert that may be done with as much ease as in the case of a Nettle; I allude to Centaurea candidissima.

This is a plant now indispensable in the flower garden, but somehow it does not take up well in autumn, and if the season has been unfavourable, it does not always furnish so many good cuttings as desirable, the consequence being that at the proper planting-out time the stock is often found smaller than it was the year before. This ought not to be, but it has frequently been the case. The plant strikes freely enough from cuttings inserted in spring, but plants to obtain them from are at that time often few, so that any mode of increasing the supply then cannot be otherwise than a boon; and in this case seed offers the readiest mode of doing so. Some persons, however, will ask, How is seed to be had? for although the peculiar formation of the seed renders it unlikely to be adulterated, it does not appear to have been yet obtained in sufficient quantity to meet the requirements of all, but it can easily enough be made to do so.

The plant is all but hardy; indeed, it may be said to be hardy in all dry situations, for we have plants at Linton Park which have been three winters in the same situation, and one of these winters was severe enough. Old plants are the only ones to obtain seed from in any considerable quantity. Let those anxious to obtain a good stock of healthy, thrifty plants of this Centaurea put in a few old plants in some dry sheltered place, collect the seed pods as they ripen, and they will find themselves possessed of more seed at the end of the season than they expected. This, sown in heat early in spring, in the same way as Lobelia seed, will produce abundance of plants, healthy and uniform in size and appearance. By judiciously pricking out in boxes or pans, the young plants will be ready to turn out in May along with other subjects, and although for a short time, while the plants are under glass and in a young state, the foliage may have a greenish grey tint, it is no sooner inured to the open air than it acquires all the whiteness of old plants grown from cuttings. I have some hundreds, obtained from seed this season, which cannot be excelled by plants raised in any other way, and it will be seen at once that all the trouble of wintering is avoided.

Centaurea gymnocarpa is likewise best obtained from seed, or rather, I should say, the best plants are so raised; for although this species furnishes cuttings plentifully enough, and these are easily struck and wintered, at planting-out time a considerable portion are often fully half run to seed, and refuse to form a single leaf. This unpleasant state of things cannot always be remedied, and ugly gaps are the consequences. Now, seedlings always grow well for one year at least, scarcely one flowering, or if they do it is merely a solitary stem or two, in no way disfiguring the plant, and easily removed. As seed is more plentifully ripened by this species than by Centaurea candidissima, I have no hesitation in recommending sowing. An accident first drew my attention to the fact. Some old plants on a mixed border had been allowed to ripen seed, which fell and produced plants; these were preserved, and there being a deficiency of cuttings, they were planted out, and their uniform growth and not running to seed have rendered me more careful of seedlings ever since.

While on the subject of plants which are best raised from seed, I must not omit Verbena venosa, which, with the exception of V. pulchella, I grow more abundantly than any other. This species deserves more attention than it often receives, for in addition to being quite hardy, it is also one of the prettiest purples we have. One or two large beds near others of Verbena Purple King afforded a good opportunity of judging of the respective merits of the two when viewed in a mass from a distance of 20 or more yards off, and everyone gave the palm to Verbena venosa. The brighter and richer tint of its blooms, taken in a body, far exceeded Purple King. It is most easily and securely obtained from seed, which if sown in heat in February, and treated the same as that of the Lobelia, &c., will produce plants flowering the same season. It may not be impossible to strike this Verbena from cuttings in autumn, but certainly not more than one cutting in a thousand will succeed if treated in the same manner as those of Verbenas, and as seed is obtained plentifully enough, it is better to raise plants in that way. To the amateur, however, it may be mentioned that the seed requires a long time to germinate, seldom coming up in less than a month.

The number of plants which are better grown from seed than from cuttings is far from being sufficiently acknowledged. We all admit the superiority of a Pinus or other tree or shrub so raised over one obtained from a cutting, but as regards smaller plants opinion is divided. Petunias, for instance, although making more sturdy plants from seed, and exempt from the fault of dying-off now and then during the growing season, are not always to be depended on for colour. There is one other plant which has risen into deserved popularity more rapidly than any I remember in the same time, and that is the Golden Feverfew, or Golden Feather Pyrethrum. By far the best plants of this are obtained in any quantity from seed.

The difference between seedlings and cuttings of this plant can only be judged of by those who have seen them together, the superiority of the one over the other requiring no explanation. I therefore advise all who have not grown this plant from seed to so raise it next spring, and they will not resort to cuttings again after seeing the two together. The seed must be very plentiful now.

There are many other plants to which the observations made above may equally apply, and I hope at some future time to return to the subject; but what I have now stated may be acted on with every certainty of success, and with a certainty of lessening the cost and labour of obtaining those and some other plants.—J. Ronson.

SELECT VERBENAS.

In fulfilment of a promise made some months ago, I now offer some further notes on Verbenas, and in doing so I shall confine myself to sorts sent out in the spring of 1868, including the collections of Messrs. Perry, Eckford, Wills, and others. I have now had sufficient experience of these varieties to offer a selection which may be depended on. On the whole I never remember seeing a better batch of novelties, or one containing so many kinds of merit; this is saying much for them, but not more than they deserve, for it is quite the exception to obtain a number of sterling varieties in the same year. I can remember having once had a number of new varieties, out of which an indifferent striped sort was the only one worth keeping.

Amongst the Verbenas of Mr. Perry, James Birbeck is conspicuous; it is a rich rosy scarlet, with a very large pip and truss, of fine form, a strong grower, and altogether a magnificent Verbena. James Day has a somewhat small well-shaped truss, and is of a very bright pleasing shade of violet; it is an attractive Verbena. Mrs. Mole has a rather loose, straggling habit; its abundant trusses of shaded lavender render it a distinct and useful kind. Shirley Hibberd, a strong-growing kind, is true to the description under which it was sent out—intense dark violet, with a small white eye, a rich-looking flower of great substance and fine form. Thomas Harris forms a compact, bushy plant, its trusses are also large, but its colour, a deep mulberry, slightly relieved by a white eye of irregular form, is rather dull; it is what may be termed a good Verbena, but it is hardly bright enough in colour.

In Mr. Eckford's lot, Isa Key deservedly occupies the first place; its colour may be described as bright rose, the trusses and pips are large and finely formed, and its bold, clear white eye gives it a novel and beautiful appearance. It is a splendid Verbena, the most distinct and striking novelty of its year. In Caroline Smith we have another splendid Verbena of a delicate shade of rosy lilac, with a clear yellow eye; it has a fine, handsome truss, and is one of the best for exhibition purposes. Next comes Imperial Purple, with an Arioste-like shade of colour, but richer; it is very dwarf and compact in its growth. This beautiful and useful variety will be cultivated extensively for bedding, its very compact, dwarf habit and rich colour rendering it peculiarly well adapted for such a purpose. A broad band of it would be very effective next shades of yellow, white, or grey. The Cure is a singular flower, curiously blotched or shaded with crimson; it forms a novel variety in a mixed bed, but I do not think flowers of this type are ever so useful or effective as those which, in addition to most other leading points of merit, possess a clear, well-defined shade of colour.

Of the Verbenas of Mr. Wills, a blue variety with a clear white eye, named Miss Wimsett, deserves mention, as being likely to hold a leading place both in the flower garden and exhibition stand for some time; it possesses all the points of a good Verbena—a robust habit, a large truss of fine form, and is of a distinct and pleasing shade of blue, rendered all the more striking by the contrast of a large white centre.

Another very distinct and effective kind is Brilliant, sent out by Messrs. Nunn & Hobday, of Norwich; it is a very bright shade of scarlet, but what renders it peculiarly striking is its very large clear white eye; its whole appearance is quite in keeping with its name. My last selection is one of Mr. Cannell's, named Beauty of Kent; in colour it is what is known as a maroon blue. This is a splendid variety, the bright, rich velvety gloss of its beautiful flowers is as attractive as it is uncommon. Madame Louis Creuze may be noticed as a distinct striped scarlet and white variety, but its growth is rather weakly, and it has a decided tendency to become mildewed.

The foregoing Verbenas have been grown with and selected from many other varieties, new and old. Probably some sorts which I have rejected may be appreciated by others, but I have a liking for decided colours.

I will conclude these notes by naming a very select dozen Verbenas for exhibition. These are:—William Dean, Brilliant, Géant des Batailles, La Grande Boule de Neige, Miss Wimsett, Nemesis, Cooling's Annie, Isa Key, Caroline Smith, Beauty of Kent, James Birbeck, and King of the Lilacs. These are all first-class varieties. Many other kinds are worthy of notice, but they are probably well known to all those who may require a more extensive assortment.—Edward Luckhurst, *Egerton House Gardens, Kent.*

THE TRANSPARENT GAGE PLUM (REINE CLAUDE DIAPHANE).

I was in Paris in 1836, and in paying a visit to M. Laffay, the originator of our Hybrid Perpetual Roses, then living at that very pretty suburb, Belle Vue, he, after our usual fascinating Rose talk, told me that he had raised from seed a most distinct and excellent variety of the Reine Claude (Green Gage) Plum, which he intended to name Reine Claude Diaphane. I was then much more interested in Roses than in Plums, but as far as I remember I saw and tasted the fruit, which I thought distinct and good. Some few years after this period, I received a tree or two from M. Laffay. The sort seemed a most vigorous grower, but the trees did not bear fruit, and consequently I was not impressed with its excellence. I seem to recollect that the trees did not bear any fruit till I had some of them potted and placed in one of my earliest orchard houses, and I then saw how distinct and excellent it was. Its robust, smooth, and almost purple shoots give the tree a most distinct character; and its beautiful Gage-like fruit, greenish yellow, covered with crimson blotches, make it an ornament to the dessert. Its flavour is most delicious, and I am sometimes inclined to think it superior even to the Green Gage, that universal favourite, its juice being less cloying and most refreshing. In cool climates it should be planted against a south wall. It is late in ripening on standards this season, as the fruit are still hard. What a long time often elapses before a new fruit is appreciated! Grapes seem the exception.—Thomas Rivers.

ROSE DOTTINGS.

Our rosarian friend "D.," of Deal, has asked why more of our readers who love the "queen of flowers" do not state their opinions of the varieties in "our Journal," and thus give to others the benefit of their experience. I remember many years ago in our pages reading words to this effect from our other grand rosarian, the Rev. W. F. Radclyffe. He said that a "rosarian" was a *rara avis;* very, very few rosarians, but many Rose-growers, and I fancy this distinction has made many of us humble Rose-growers chary of offering our mites in the discussion. I had certainly been meditating a notice of my favourites, and as often thought I could add nothing of any value. The meditation might have ended in smoke, instead of pen and ink, as at present appears probable, had not our good friend "Wiltshire Rector" unexpectedly turned up to visit me in my new quarters. Amongst other questions put to me by "our mutual friend," he had the coolness to ask if I knew whether one "Y. B. A. Z." was dead, as nothing had been heard of him for some time. I was driving him about in a carriage at the time, and consider a debt of gratitude due to me from all readers of "our Journal" that I did not at once in a proper damaging manner upset the carriage, and turn our worthy friend out. For this present Rose infliction, then, "Wiltshire Rector" is answerable. I might have replied to our friend's query more truthfully than the Irishman, stunned in a scuffle, who, when roused and asked if he was dead, replied, "I am not dead, but I'm spacheless." Circumstances have made me "spacheless" as regards "our Journal." Like my shifted Roses, lacking the bountiful supplies of water which our great rosarian would give them, I have not exactly settled down into the fresh soil, and my time has been fully occupied.

In a former Rose communication I stated my partiality for the Manetti stock. Amongst my brother amateurs in my present little Wiltshire town this stock is not appreciated as it deserves to be. We have a very hungry soil, one like Pharaoh's lean kine that devour the fat kine, and are none the fatter for the meal, and one of our best amateur Rose-growers here, who

spares no expense in the culture of his favourite flower, says he means to take his trees up every autumn, and give them fresh food, &c. The great majority of his plants are on the Briar; they are all well tended, thoroughly watered and fed, and his plants are in prime condition; this year, however, hundreds of his Maréchal Niel buds dropped just as they were expanding, the core being rotten, the stem rotting also. My friend has six or eight plants against his wall in robust health, with shoots 10 feet long. Just as the flowers were on the point of opening we had very cold winds and rain. I went over his garden before our local Rose show (amateur); it was pitiful to see the ground strewn with buds. I pointed out to him, however, a break in the wall where two or three buds were sheltered from the rain and had been kept dry; these were perfectly sound, and made beautiful blooms; and I fancy I learnt "a wrinkle" from that accidental hole in the wall. About the same time I saw in his garden a Marie Baumann on the Manetti that was worth going a long way to see—some six or eight blooms, all "fit for immediate exhibition," open at the same time. It exerted the same spell on its master as on the Rev. W. F. Radclyffe; he never tired of looking at it, declaring that he never knew what a real Rose tree was before! His partner, an equally enthusiastic Rose-grower, showed at our annual meeting six blooms, nearly all he had open, which obtained easily the first prize in their class—they were triumphs of Rose-growing; Maréchal Niel, Triomphe de Rennes, and Cloth of Gold especially. But this gentleman also exhibited as a single a bloom of Maréchal Niel, as a curiosity, for it was too far gone. I do not think I exaggerate, and certainly would not willingly do so, but I believe it must have been 6 inches across and 3 inches in depth. Many of the visitors could scarcely believe their eyes, and it was likened to a Cabbage! The Maréchals that do best here are budded on the Briar low down, almost underground. I had budded it on the Gloire de Dijon at Hinton, but had not seen it bloom before I left. I fancy the Teas generally do not like the Manetti stock; whilst I well recollect some years ago somebody—was it Mr. Rivers?—saying in "our Journal" that Gloire de Dijon would prove the best stock for the Maréchal.

The most successful Rose-grower in our amateur society—he may be fairly called a rosarian, I think, as he has certainly introduced one seedling—had tried the Manetti extensively. This year his Manetti plants have suffered severely from mildew, and he threatens to make a clean sweep of them. Is it the fault of the stock?

But to come home. What a pity it is that that most lovely Rose Cloth of Gold requires such an "age of years" to ripen into womanhood. Planted against a house in a favourable aspect, adorning it with its beautiful foliage, it will, when ten or twelve years old, bloom abundantly; in my old locality several trees were noted. Does it not repay the waiting? Triomphe de Rennes is another great favourite of mine; vigorous in growth, free in blooming, beautiful to the eye, delightful in perfume, but disliking, as my experience goes, a sharp winter, yet in my estimation among the first-raters of the Rose world. Climbing Devoniensis is a most useful Rose, but will our master rosarians give us a hint in the treatment? I have seen one this year which has sent up a shoot fully an inch in diameter, still growing, and fully 16 feet long now. What ought to be done with it? Should its progress have been nipped in the bud? Will cutting it back to 3 feet in the spring make it bloom at every joint? Anyway, there are some who say that it requires more knife than it usually receives. I am surprised that "C. W. M." does not name Souvenir d'un Ami, one of the most lovely Roses I have ever seen, faultless in shape, of lovely colour, and as a pot plant most graceful. Sombreuil this year has disappointed me; it is hardy, and a useful Rose all the same.

Of Hybrid Perpetuals Charles Lefebvre is magnificent; it certainly is not so full as I should like, but it is kind in its nature, and will do well on the Briar, the Manetti, or on its own account, and will never fail to have admirers. Alfred Colomb and Marie Baumann are Charles Lawson's equals, if not superiors; both are first-class Roses, and the former is very kindly in taking hold when budded. Mdlle. Marie Rady is not much behind these. But what has become of Rushton Radclyffe in some of our catalogues? Is it discarded? and wherefore? It may owe something to its name, but some of the finest specimens of the Rose I have ever seen are from this discarded plant. Exquisite in colour and form, with the petals so evenly and regularly placed, it has attracted the attention of many of my friends; it is, however, a rather tender Rose. With me it is vigorous in growth. It is on the Manetti.

In my hands General Washington has been continual disappointment. Year after year have the most splendid buds of immense proportions appeared, and just as it was opening it would split to pieces. I still have one plant on its own roots, and I have hopes that it will behave better in Wiltshire. If it open well it is worthy a place in every collection. What of another American—viz., the Noisette America? I have never succeeded but once in obtaining a good bloom of it; that, however, was worth waiting for. It seems to me that the petals are too large and too numerous, and the lapping-over such that it cannot overcome. Mr. Keynes shows it in perfection as an opening bud, but even in his stands I have not seen it fully expanded. Both these Americans suffer, it seems to me, from a plethora of petal. Madame Victor Verdier, an improvement on Senateur Vaisse, is always useful, like Senateur. Both are magnificent Roses, and will do on either stock.

I quite agree with "C. W. M." that Duchesse de Caylus is of exquisite form and of fine colour—in fact, in every way it is a first-class Rose. Its only fault, perhaps, is a deficiency of size. Pierre Notting and Leopold Premier are also first-rate; the latter about here has this year come constantly with a large green eye. I think they both prefer the Manetti stock. Comtesse de Jaucourt will, I fear, prove coarse, though for colour it is desirable. Madame Moreau is perfectly distinct; that is something in these days. It is apt to appear crumpled and not to open freely, but to me its distinctness is a very great point. Xavier Olibo for brilliant richness of colour is perhaps unrivalled, but it opens badly, and when fully expanded is thin and poor. For exhibition purposes we want flowers that will at least retain their shape for a few hours, and not expose the nakedness of the land before even the judge's eye has been over them. Hippolyte Flandrin is indeed a prodigy when you can get it, but there's the rub. Is it true that its first year's growth is the only growth worth having? If so, this must greatly detract from its merits. Mdlle. Marguerite Dombrain is all that "C. W. M." thinks—it ought to be in every collection; still, we have old Roses very like it—to wit, Louise Peyronny. But what of its respected parent, I mean as a Rose? Why is the Rev. H. Dombrain discarded? It is very distinct, in colour often almost mauve, with a glossy brilliant softness which is most pleasing. Moreover, it is an abundant bloomer and very vigorous. I cannot give it up. Like many others, a few more central petals would improve it. Monsieur Noman is indeed a splendid Rose. Certainly, the late blooms this year are poor, but then what a summer! Does not that account for the poverty? But if Monsieur Noman is grand, Madame Noman is sweetly pretty; to be sure it is small, but then who ever saw a fine large man take a large woman for his wife? So we must be content as regards size, but the fimbriated edges of the petals and its lovely shape make amends. Of another white, Boule de Neige, the same may be said as to size; it is, however, a pure white, and an acquisition. Still, among the whites, why not more of Mdlle. Bonnaire? It is a beautiful Rose in every way with me, and carries the largest blooms that I know amongst the white Remontants.

Then who would be without John Hopper, a first-rate English Rose? There is something in the latter that ought to make us cherish it. Moreover, its name is pronounceable in these days of "Who's who." La France and Madame la Baronne de Rothschild are both promising Roses, but as yet I cannot speak from experience. There is another Rose that I do not see so often as I fancy its merits deserve, that is Lælia; it is a great favourite of mine. Maréchal Vaillant is another old friend for which I must always find room. It may be somewhat straggling in growth, but in colour, shape, and perfume it is very good; and it has this advantage in the garden, that it flowers rather later than the others, when a fine bloom is becoming rare.

Amongst the whites I have omitted one, a great favourite of mine, Louise Magnan. It is a gem of a Rose, but has had with me a serious drawback, which is, that even in its second year it is very easily broken by the wind at its junction with the stock. I have lost several in this way, even when the point of junction was 2 inches underground.

After all, were I forced to select one single Rose as most suitable for every purpose, my vote must go for Gloire de Dijon—free and vigorous in growth, hardy in constitution, profuse and constant in bloom, almost our earliest, and certainly one of our latest (I once picked a beautiful bunch of buds on January 1st), of glorious colour and delicious perfume, good

in size and beautiful in form—over an old wall, against the side of a house, in the biting north aspect, or the sunny south, commend me to glorious Gloire, our constant, firm, unflinching friend. My old tree at Hinton covered a space at least 16 feet square, and I once counted upwards of four hundred blooms out at the same time.

Time and space fail me to write of many of my older favourites—Jules Margottin, Mrs. Rivers, Madame Vidot, Baronne de Noirmont, François Lacharme, Comtesse Cécile de Chabrillant, a gem; Auguste Mie, old, but often unsurpassed, in my humble opinion; Baronne Prévost, Le Rhone, Madame Charles Crapelet, very lovely; Acidalie, small, but perfect in form, though very soon dropping its petals; Madame Hector Jacquin; Lord Macaulay, brilliant in colour, very free in blooming; Vicomte Vigier, a first-class Rose; and Souvenir de la Malmaison, magnificent though old, but a fine-weather Rose. Princess Mary of Cambridge, like its royal godmother, must always be popular.

Accidentally, the other day in an old rectory garden I saw some aged standard Rose trees, the stems were of giant proportions; but there I renewed an acquaintance with an old favourite almost forgotten—viz., Boula de Nanteuil; and truly, though flat, it is still a grand Rose. Amongst these Roses was another old friend, my intimacy with which has not been interrupted—namely, Coupe d'Hébé. It was, as always, lovely and elegant. Is a Rose collection complete even for us poor "Rose-growers" without her? or, again, without Charles Lawson, a giant in bloom, and lavish of bloom in spite of the size? or, again, beautifully formed Paul Ricaut? I recollect old Thomas Cole, of the Wellow Rosery, near Bath, a name well known among rosarians and Rose-growers in the west, was wont to remark that were Paul only a Perpetual no Rose would equal it. Another of his great favourites before the introduction of Gloire de Dijon was Lamarque. It was in those days of old his Rose of selection; but then it is decidedly tender; and oh! that winter of some eight years ago, what havoc it played with this identical Rose! Many a grand tree in my "auld counthrie" was either entirely destroyed or reduced to most diminutive proportions.

I am running on, and need, perhaps, a thorn from one of my pets to stop me; but just a word on stocks. "C. W. M." says that to all "true rosarians" "the Briar is doomed." Well, as I do not profess to be a rosarian, only a poor Rose-grower, I suppose I shall still stick to the old friend for some things. I have before said that my belief in the Manetti is unbounded; still, my experience in budding Tea Roses says they have not the same high opinion of the Manetti that I have, and I confess that, after seeing the reasons, my faith in the Manetti as a stock for Tea Roses is considerably weakened. The Noisette Roses also, I fancy, do better on the Briar; still, in general gardening for effect, it is often necessary to have Rose trees as standards. I am not so certain that the Manetti answers budded, say, 2 feet from the ground. I have no doubt that it does answer with some Roses—that is, if seeing is believing; but in these days, when some suggest that you should believe nothing that you hear and only half what you see, it may, perhaps, be a question whether my eyesight has been at fault, yet generally for this higher budding I do not fancy it will answer. We must then fall back on the Briar, and, setting aside the annoying suckers, some of our best Roses behave grandly on it. No one who has seen such Roses as Jules Margottin, Madame Victor Verdier, Charles Lefebvre, Gloire de Dijon, Baronne Prevost, Charles Lawson, Maréchal Vaillant, Monsieur Noman, and others doing well on the Briar would cry out much against that stock for them. We need to study each Rose for itself. Some, as Louis XIV., prefer standing on their own merits; some, again, prefer the Briar; while the great majority will do well, or better, on the Manetti than on anything else. We all have our whims, why should not Roses?—Y. B. A. Z.

P.S.—My advice to "C. A. G." *in re* Manetti stock, is to try a few. Any impartial person will soon see the difference of the rapid growth and free blooming, compared to the same Rose on the Briar. The Manetti has one disadvantge—that its foliage being larger than the Briar, it is by young hands often mistaken for the actual Rose, and a sucker I have frequently known nurtured and tended as if certain to produce a store of exhibition blooms. With the Briar such an error is impossible, because it is discovered immediately. If the disbudding is thorough and deep in the Manetti cutting, it can very rarely happen there.

I must again repeat that I have seen very respectable heads on the Manetti budded as a half-standard; but as seeing, even, is not always believing, I agree, humbly and at a long distance, with the Rev. W. F. Radclyffe, that the right way is to bury the junction, and many Roses will the first year throw out their own roots.

The Rev. W. F. Radclyffe writes, "The Manetti stock is not an imposition." If he will allow me, I will say ditto to him as strongly as it is possible or allowable for me to say. It has been my lot during the last few years to be constantly seeing two of the largest nursery gardens in the neighbourhood of Bath. One does not exhibit, the other is continually to the front: both have a large stock of Manetti-budded Roses, and in both it is considered for general purposes first-rate; it is in one of these gardens that I have seen the successful half-standard Manetti budding; but the soil where these half-standards were is peculiar—very rich, and it had formed at one time, if I recollect rightly, the bed of a canal. If the Manetti stock were the only "imposition" in the gardening world, we should all of us have reason to be proud of the purity of our hobby.—Y. B. A. Z.

INFLUENCE OF THE STOCK UPON THE GRAFT.

[Mr. Fenn, of the Rectory, Woodstock, whose specimens of Ribston Pippin Apple, from trees grafted on the Blenheim Pippin, were brought before the last meeting of the Royal Horticultural Society's Fruit Committee (see page 245), has favoured us with the following account of his experiments.—Eds.]

Eleven years ago I happened to be near an old Ribston Pippin tree, in the last stage of canker; near it were some old but most vigorous trees of Blenheim Pippin. (This excellent Apple was raised by a man of the name of Kempster, of Old Woodstock; I saw the original tree when I first came to reside here, and afterwards when I wished to procure a piece of its wood as a memento, I found that it had been cut down, and given to the fire.) At the time I saw the above-mentioned trees so flourishing by the side of my favourite Apple, the Ribston Pippin, it occurred to me whether it would not be possible to infuse new vigour and strength of constitution into that stunted and unhealthy form of Ribston Pippin generally met with about the country, producing ill-conditioned foliage, and immature fruit. With this view I sowed some pips of the Blenheim Pippin, as being most likely, from the healthy, vigorous character of the variety, to produce a stock that would bring about a change for the better; also to prove whether the influence of fresh and vigorous sap from a young and free-growing stock would remedy the destructive canker in the bark, and, as a consequence, add fresh life to the Ribston Pippin.

By the time the second year's growth of the seedling Blenheim Pippins had arrived, I singled out the strongest stock of the batch, one having a fork—that is to say, branches springing from its base. This stock I grafted with two miserable-looking scions from the diseased Ribston Pippin, both of which to my astonishment succeeded, and by the following year they had made strong growth. The tree was placed against a wall, and I then determined to carry my experiment further by removing one of the grafts just above its union with the stock. In order to do so, I removed with a penknife about 2 inches of bark all round quite down to the wood, by this means causing the formation of a cicatrix. Further, I tied damp moss round the limb, then bent it down, and fixed it horizontally upon the earth, with which I covered the moss, keeping all constantly moistened during the summer and autumn. The limb which was thus ringed rooted into the moss and soil readily, and in the following November, when it was safe to do so, I severed the limb, or graft, entirely from the tree, and planted it in a pot, where it has continued to make good and clean growths of wood, though of not nearly so vigorous a character as its fellow scion, which is still growing on its stock raised from the pip of the Blenheim Pippin.

The tree against the wall produced its first fruit in 1866, and it has produced good crops ever since, especially during the present unfavourable season. The bark of the stem and branches is remarkably smooth, and free from canker, and the foliage is vigorous and highly developed, partaking very much of the character of that of the Blenheim Pippin, whilst the fruit bear a striking resemblance, in general form, to those of the Ribston Pippin, and though smaller this season, are usually about the size of those on a healthy tree of the latter variety. In texture of flesh the fruit is not so solid as that of the Ribston Pippin, and unfortunately it has not half the flavour of the

latter, being a combination of the flavours of the Blenheim and Ribston Pippins. I think it one of the best, if not the best, of early autumn Apples which I know for pies, giving in August that mellowness which one usually has to wait for in Apple pies till March or April; thus singularly advancing on the Blenheim Pippin, which in its early maturity has a mealy, green rawness when cooked.

I have been waiting for some years with considerable interest for fruit upon my second tree in the pot, and I am happy to say it has this season ripened three fruit, with, on my part, great battling against insects. I cannot, in fact, I dare not, taste one; all must come before the Royal Horticultural Society's Fruit Committee; but if the property of smell can lend me hopes, then I have maintained the Ribston intact, and restored the wood to its pristine health. Two of the fruit are not perfect in shape, but this I attribute to the season; the third is perfect in shape, and true in appearance; but like their namesakes against the wall they are small. The tree is growing in an 18-inch pot, and during its growth it has had four shifts. It has ripened its fruit in the open air, and in consequence of the mildness of last winter it was not placed in the orchard house.—Robert Fenn, *Woodstock*.

THE HURRICANE OF SEPTEMBER 12TH IN GUERNSEY.

It seems naturally reserved for us dwellers on the stormy coasts to relate our experience of the violent storms which periodically devastate our shores. I have thus several times recorded here our experiences of very severe gales, but that of the morning of Sunday, September 12th, was the most fearful of all, and, as such, requires a few remarks on its characteristics.

Though so near the autumnal equinox, no one could forecast so sudden a storm; but the past summer has been altogether remarkable, and what the winter will be can only be imagined, for we have no reliable data nor experience to guide us. It seems as if destructive currents of air must be expected to result from the various marked alternations of rain, drought, and general absence of sunshine. We are, therefore, promised tidal waves of unusual heights, and concurrent storms, nor can we affect to doubt their sad possibility.

Not only was the hurricane of September 12th sudden and unexpected, but it was, perhaps, also the most terrific ever felt in these islands. On the Saturday afternoon so little appearance was there of any unusual disturbance in the atmosphere that my wife and myself were encamped close to the sea, and in the immediate neighbourhood of a venerable cromlech, well known to tourists at Perelle Bay. At about 3 P.M., a heavy squall blew down the awning of our tent, and a drenching rain warned us to strike tent and return home, to which we drove subsequently, little anticipating the night that was to follow. By nine o'clock the barometer had fallen 3½-tenths, and was then 29.153, and the pressure of the wind per square foot was already nearly 20 lbs., but during a squall it reached 30 lbs., or 80 miles per hour. We carefully secured the various glass houses, taking especial care to exclude back currents—and this I would here strongly impress on others, for nothing cracks glass so speedily—the wind being then from a dangerous quarter, S.S.W. Having had nearly 100 feet in length of orchard houses blown down nine years ago, and a somewhat less accident in 1856, experience has shown what is needed in ordinary gales of 30 lbs. or 35 lbs. pressure. Only last winter we experienced, however, the pressure of 45 lbs. to the square foot, but this occurred with a safer direction of wind, and was of short duration. Still it was a surprise to me, thinking, at that time, that a pressure of 35 lbs. was something extremely perilous to glass, as it prostrates many a noble tree. By midnight the wind raged with fearful strength from the dangerous quarter S.W., which usually takes our numerous glass houses in these islands obliquely, inferior only in risk to them to a full blast directly in front. Then, and then for the first time, did we hear the roaring of a hurricane of the power of no less than 55 lbs. pressure, which equals a velocity of 105 miles an hour! Our old house rocked violently, and the sound of the falling of slates and the cracking of glass was distinctly recognised, indicating some dangerous unroofing, which the daylight verified too surely. Vivid lightning accompanied the squalls, and loud thunder, with rain. By the dim light it was easy to see prostrate trees on the lawn. No one slept, and we "longed for the day."

By 6 A.M. the violence of the gale had sensibly diminished, and the anemometer recorded at that hour a pressure of 31 lbs., or that of a rather severe equinoctial storm on the seacoasts, which, however, was comparative quiet to us. The barometer rose to 29.515, sea-level.

Of course the damage done was immense, chiefly, however, to the trees of the island. Numerous chimney-stacks fell, the fishing boats moored in the several bays were nearly all swamped, and many injured, and numerous roofs of houses were damaged. The gardens seem to have suffered the most; the fruit crop is irreparably spoiled for the market, to the sensible loss of the small growers here. Trees of all kinds exhibit the forlorn appearance, noted in the English journals, of having been scorched as by fire. Although the violence of the atmospherical current seems sufficient to account for this blackened look, may it not also be due to the presence of salt in suspension in the air? A seemingly inefficient obstacle appeared to turn the stream of air aside or upwards in certain cases, and the protected portions are as healthy as usual, lying close to black and scorched leaves. Does not this point to the unrecognised value of thin screens of foliage, living or faded? Had I possessed screens of sufficient strength for open-air Peach trees they should, without doubt, have been carefully spread over the autumnal foliage. There is more care really required in protecting the leaves of plants from external injury than in merely encouraging their free growth: hence one value of glazed protections, which effect this without obscuring the sun's rays.

To my great astonishment this unusual pressure of air has not done the damage to glass which might be feared. The largest panes of glass have stood as well, if not even better, than those of the ordinary size. The first-named are thicker, and I therefore conclude that a wide pane of glass of 21 ozs., or thereabouts, is safer to resist a squall than a much smaller one of only 16 ozs. The fact of these large panes being as secure as the more ancient small ones is encouraging to builders of orchard houses. All houses, however, should be solidly constructed, unless in unusually sheltered localities, as it is the vibration which loosens the putty, and causes the glass to slip down or break. For a gale from any quarter, all ventilators should be closely shut, and entrance by the doors avoided.

These destructive storms should prove that fruit culture in the Channel Islands has its peculiar difficulties. There is nothing more injurious to fruit and foliage than high wind. —T. C. Bréhaut.

BEDDING PLANTS AT THE ROYAL NURSERIES, SLOUGH.

If anyone wishes to form some idea of the value of certain plants for bedding purposes, he cannot do better than pay a visit to the Royal Nurseries, Slough, during the summer months. Every year Mr. Turner beds out on a considerable space of ground, occupying one of the most prominent positions in the home nursery. There is little attempt at a set display, rather there is to be seen a very interesting trial ground occupied by all the leading new kinds of Pelargoniums of home and continental origin, Verbenas, and the like. One piece of ground at the east side of Mr. Turner's dwelling-house consisted of nineteen beds some 25 feet in length by 3 feet in breadth; fifteen of these were filled with Nosegay and Zonal Pelargoniums, two with Variegated Pelargoniums, and the two end beds were used as small ribbon-borders by way of imparting a little ornamentation to the whole. Somehow things appear to do uncommonly well at Slough, let the weather be never so dry; and this summer, while many parts of the country were suffering from a drought almost as disastrous in its effects as that of last year, at Slough plants looked as if they at least were unchecked by it in the least.

Looking over the Zonal Pelargoniums, the following were first-rate as bedders:—Gloire de Corbeny, carmine salmon, with pale edges, immense even trusses of bloom, and dark zonate foliage. This stands the sun remarkably well for a salmon-coloured variety, the general charge brought against such being that the flowers burn and become sadly disfigured. Virgile, salmon, with carmine centre round a large pale eye, dark zonal foliage, excellent habit, and splendid trusses of bloom. Forester, dark salmon rose tinted with purple, large trusses of bloom, good habit, and dark zonate foliage. Lucius, bright pale orange rose, very large and bold trusses of bloom, faintly marked zonate foliage, and good habit. Jean Sisley rich bright crimson, white centre; very bright and showy. Dr.

Ricci, a grand new continental variety, having brilliant scarlet flowers, pips very fine, and magnificent trusses; foliage broadly marked with a dark zone; excellent habit. Theodore, soft salmon rose, a finely-shaped flower, and striking dark zonate foliage; one of Messrs. Windebank & Kingsbury's fine new varieties. Warrior, brilliant deep vermilion, immense trusses of bloom, plain foliage; very fine, one of the hybrid Nosegay type. I have no hesitation in heartily recommending the foregoing to growers of this popular flower. Of the Nosegay type, the following are well worthy a place with those just described:—Gloire des Massifs, bright orange crimson, very fine trusses of bloom, foliage slightly zonate; a grand bedder, most effective in this relation, and one to be looked after by those desirous of procuring something new and good. Monsieur E. Buenzod, soft pink, faintly zonate foliage, very dwarf grower, and though furnishing very fine trusses of bloom, remarkably free. Both these are new continental varieties. Nosegay St. George, one of Mr. William Paul's flowers, deserves the highest commendation as a bedder. It is a plain-leaved variety, with rich deep crimson flowers, good trusses, and remarkably free; one of the flowers that deserve a place in every garden.

In another part of the grounds I saw a new continental variety of very considerable promise under the name of Amedée Achard, the flowers rose, tinted purple, the upper part of the flower dashed with orange, trusses large and bold, dark zonate foliage, and remarkably dwarf close habit, and an excellent bedder. Mr. W. Paul's Blue Bell was succeeding remarkably well here, and the same experience of this fine new variety has met me wherever I have seen it during the present season. Rising Sun is another excellent variety, very dwarf in growth, and having good trusses of bright crimson flowers, and extra fine as a bedder. There was also an excellent Nosegay variety with rich deep crimson flowers, something in the way of Le Grand, but brighter. Unfortunately I could not discover the name of it.

Of the Variegated Zonal section of bedding Pelargoniums, Lady Cullum and Sophia Dumaresque are really good bedders, and deserve to be commended as such. By the side of the path skirting the old Bath coach road, were a couple of large stone vases, one filled with Lady Cullum, the other with Sophia Dumaresque, and both edged with blue Lobelia. These were most effective objects, the Pelargoniums being luxuriant in growth and handsomely coloured. Of the Silver-edged section, Bijou Improved is an excellent and most useful bedder; having more white than the old Bijou, it is much softer-looking, and it bears deep crimson flowers. Very fine indeed was old Flower of the Day, by no means to be despised, though surrounded by such a large group of new aspirants for popularity; but, alas! how few are likely to run such a lengthened career of usefulness as the perennial and constant Flower of the Day. It will not be given up just yet by many.

A large bed of Chrysanthemum Sensation, the creamy-variegated kind, mingled with King of Tom Thumbs Nasturtium, had a very pleasant appearance. The dark hue of both flowers and foliage of the latter, contrasted admirably with the former, and were most effective. An oval-shaped bed of the old Ivy-leaf Pelargonium was just as effective; there was a kind of natural unevenness about it that rather added to than detracted from its usefulness.

Mr. Turner's new Tropæolum Ochrolencum promises to be a valuable golden-leaved bedding plant, the leaves being purely of a creamy-golden hue. It grows freely and does not bloom, or if it does, only produces a few half-developed flowers. For colour, Pyrethrum Golden Feather is inferior to it, and the Tropæolum promises to displace it. It came up somewhere about the nurseries self-sown, and will have to be propagated by cuttings.

There were also to be seen several effective beds of Verbenas, inclusive of Mr. Perry's new kinds. Of the latter, Chastity, pale pink; and Richard Dean, shaded plum purple, with large and showy pale eye, make capital bedders, the latter especially, the habit being remarkably good. King of Lilacs, of a somewhat pale hue of colour, makes an excellent bedder also; and old Géant des Batailles, and the almost as old Firefly, were both remarkably good as bedders also. A variety named Delicata, with violet rose flowers, was very pretty and attractive, and has a somewhat unusual dwarf and compact habit for a Verbena.

Delphinium Madame Zelandais should be noted by those—and it is to be hoped their name is legion—who cling with a loving regard to the somewhat neglected class of perennials. It throws up a handsome spike of double flowers, in form like that of a Hyacinth; the individual flowers are of a pale ground heavily edged with light azure blue.

But it is worth while glancing for a few minutes at some aspects of Mr. Turner's garden ornamentation, or bedding-out. I have already stated that at each end of the Pelargonium beds something had been done in this way. There was also a ribbon border on the west side of the beds running at right angles to them, and this was planted with a background of Perilla nankinensis, then a line of Stachys lanata, then Pyrethrum Golden Feather, then an outer line of blue Lobelia. This was neat and soft in appearance, even though there was such a glare of colour behind it. On the north side there was a line of Madame Vaucher white Pelargonium at the back, then a line of Perilla, Stachys, Pyrethrum, and blue Lobelia as before. On the south side there was a background of the Catmint, Nepeta cæsia, with a profusion of lavender-coloured flowers, said to come into bloom in May, and continue all the summer in flower; then a line of the Perilla and Iresine Herbstii mingled together, contrasting the one with the other, and yet nicely blending; then the Golden Pyrethrum; then blue Lobelia, and an outer edging of Cerastium tomentosum. On the east side of this series of beds is a main walk running through the grounds from south to north. Here was a ribbon border not without some elements of originality in its construction and some novelty of arrangement. The background was composed of a line of dark and light Fuchsias, with white-corollaed varieties at intervals. These Fuchsias were about 2 feet in height. Then a line of Nosegay Pelargoniums composed of two plants of Duchess of Sutherland and one of Lady Constance Grosvenor planted alternately; next a good line of yellow Calceolarias, then an excellent line of the Nepeta in full bloom, with Irish Yews at intervals, a permanent row of them belonging to the border. A line of Iresine Herbstii and Cerastium candidissima mingled together followed, then a line of scarlet Pelargoniums, next the Pyrethrum, then a line of the blue Lobelia and crimson Ivy-leaved Pelargonium mingled together, the crimson flowers of the latter nicely blended with the blue of the Lobelia, the whole edged with a broad band of Cerastium tomentosum. There was a pleasant stiffness about this border, so unlike many ribbon borders where an undue and offensive glare of colouring is the great feature.

Around the square span-roofed conservatory were other flower beds, some of which were of more than average merit. Two of these have already been mentioned. A third was of the shape of half a circular band, and was filled with Golden Fleece Pelargonium mingled with Amaranthus elegantissimus. This is a very showy plant indeed, and will always prove a great attraction in localities suited to it. The arrangement of another bed struck me as being remarkably good, but the shape of the bed was altogether unique. Imagine a horse with the legs and head close behind the ears severed from the body, and the shape of the bed can be realised. A line of Echeveria metallica was placed along the centre, on each side was Amaranthus melancholicus ruber, then on each side again Centaurea candidissima, and an outer edging of blue Lobelia. Another good bed was a long oblong in shape, with a specimen of Coleus Verschaffelti in the centre, and from this a line of Echeveria metallica ran to each corner. The angles at the ends were both filled with Pyrethrum Golden Feather; and those at the sides, one with Lobelia Erinus speciosa, blue, the other with L. Paxtoniana.

On the north side of the conservatory was a large circular group of plants, the arrangement of which was of such a nature as to make it worthy the attention of the promoters of horticultural exhibitions anxious to gain some idea of disposing their forces, differing essentially from the stereotyped plans so invariably followed. Frequenters of the Royal Nurseries will remember that on the north side of the conservatory there is a broad open gravel space. Here Mr. Turner grouped twelve standard Laurustinus in pots, but far enough apart to admit of a free circulation of air among their heads. Then in among them were placed flowering plants of Kalosanthes coccinea, scarlet and other Pelargoniums, and various plants, quite filling up the intervening spaces; then Humea elegans and plants of Campanula pyramidalis in pots were placed round these; next came a circle of Centaurea candidissima, then one of Amaranthus elegantissimus, another circle of a dense-growing Saxifrage, with an outer edging of blue Lobelia, all the plants being in pots. Finally, the plants of Campanula pyramidalis had been bent down outwardly, and fastened to the ground between the pots of the blue Lobelia. The effect was surprising—it was a good idea well expressed.

In a first-class nursery like this, with its extensive stocks of plants of all kinds, there must always be something of interest to the practical horticulturist. Much that is interesting and instructive I have touched on, but one more allusion and I have done. On the front stage of the long Pelargonium house was a large number of plants of the double variety, Gloire de Nancy, young stocky plants covered with large trusses of bloom. They were simply growing in large 60-pots, and yet were in finer condition as regards health and quality of flower, than many more pretentious plants growing in larger pots. They had become pot-bound, and then were kept freely watered. This was the simple explanation made to me. It was "a wrinkle," and one worth placing before your readers.—Via.

MESSRS. CARTER & CO.'S CRYSTAL PALACE NURSERY.

The increase of this nursery, both in extent of land and extent of glass, during the last seven years has been most remarkable. Seven years ago it was but a small place, chiefly devoted to growing bedding plants; now, not only these but nearly all descriptions of ornamental plants are cultivated, and by a recent purchase of land there will soon be 40 acres of ground occupied for nursery purposes. A portion of this area is at present in grass, but even without it the additions made since 1862 have been very important; for instance, a trial ground of 6 acres, in which are tested the samples of seed furnished to the firm from its own extensive seed farms, as well as from independent growers. There are now eight large glass houses variously occupied, besides twelve ranges of pits, all of which Mr. Boston, the energetic manager, keeps constantly employed.

After passing through the show house, where Palms, tree Ferns, and a variety of other ornamental plants are effectively arranged beneath the Black Hamburgh and Buckland Sweetwater Vines on the roof, a flower garden is reached, the bright colours of which catch the eye on the way to the nursery from the Forest Hill station. Here Abutilon Thompsoni had been planted out at the end of May, and formed a very attractive front row, its green foliage mottled with yellow being so distinct in character from the golden-leaved Pelargoniums. How late in the season the plant may be trusted out of doors remains to be seen. Sempervivum californicum, Echeveria metallica, E. secunda glauca, and the dark reddish brown-leaved Echeveria sanguinea, were also planted in considerable numbers; there was likewise a seedling Echeveria, called metallica glauca, which is of free growth, and of the colour of E. glauca. Alternantheras, plunged in pots, were not doing well, with the exception of A. amabilis; but A. spathulata, though not flourishing here out of doors, makes a fine pot plant. Among Pelargoniums, Mrs. Dunnett and Sir Robert Napier were noticeable as two of the best of the Tricolors, the latter being especially conspicuous by its very broad and dark zone. Conspicuous among self golden-leaved kinds was Carrie Fowler; and among the silver-variegated, Snowdrop, which is of free growth, and exhibits a pure white variegation, but like others of its class it has the fault of cupping its leaves, no doubt owing to the green centre growing more rapidly than the white circumference.

Proceeding to another part of the grounds we find a stock of Strawberries in small pots of a made size, deeper than thumbs and rather less in diameter, being 3 inches deep by 2½ in diameter. These are very cheap, and can be ranged together more closely than pots of larger diameter—an object where room has to be found for 100,000 pots, which was about the number here. Mr. Boston has now all his Strawberry runners in pots, instead of taking them up; and so with bedding plants, each cutting has its little pot, so that the roots are not interfered with when the plants are sent out, and consequently the plants soon become established in their new quarters. It may here be mentioned that the spent hops from the London breweries, and which can be had for little more than the cartage, are used as a plunging material and for mulching, and answer exceedingly well, being moist and affording for a time a slight bottom heat. A large number of herbaceous plants are grown, and most of the new Clematises are likewise represented; the double-flowered one, John Gould Veitch, had been magnificent, and was still fine, though its beauty was declining.

The stove and Orchid house, with which is combined the propagating house, forms a span-roofed range 102 feet in length, divided lengthwise by a glass partition, and crosswise into three compartments. These contained good specimens of Phalænopsis Schilleriana, Vandas, Aërides, Lælias, Dendrobiums, Odontoglossums, and other Orchids, nearly all of which were out of flower, and a variety of ornamental-foliaged plants, as Dichorisandra mosaica, Anæctochils, new Marantas, the beautiful Bertolonia guttata, and Sonerila margaritacea, Eranthemums, Fittonia argyroneura, Passiflora trifasciata, &c. There was also an excellent plant of Anthurium Scherzerianum. In a basket was a moderate-sized Monstera deliciosa, which, though it has been recommended for cultivation as a fruit-bearing plant, will probably continue to be grown merely as one remarkable for its foliage, the fruit, unless used at exactly the proper state of ripeness, containing irritating spicula, which more than counterbalance its Pine-Apple flavour. The propagating house, which formed the back half of this range, was filled with cuttings of miscellaneous stove and greenhouse plants, grafted Camellias, Pereskia stocks for Cacti, &c. Another house, 90 feet long by 15 wide, was being filled with cuttings of Sir R. Napier and other new kinds of Pelargoniums, chiefly Tricolors. These occupied one division; another contained several promising seedlings, fine specimens of L'Elegante, Ivy-leaved, just changing to the rose-coloured state, and several excellent plants of double kinds, most noticeable among which were the dwarf, compact, rose-flowered Marie Lemoine, and Wilhelm Pfitzer, a fine scarlet. Several of the best specimens, however, had been sent to the Hamburg Exhibition. A third division contained Coleuses, and one plant of Her Majesty was grafted with twenty-eight varieties. In this division, too, was Iresine Lindeni, which, if it prove hardy enough, will, from its richly-coloured foliage, prove valuable for bedding.

The Fern houses contained a very good general collection, among which, though not large, were several examples of the lovely Adiantum farleyense, Selaginellas of various kinds, and a number of seedling Ferns. Azaleas of the leading kinds, in 48-sized pots, nearly occupied one house, and a pit as well; and a house 90 feet by 24 feet contained Vines for planting, most of which, however, with the exception of those forming an archway over the path, had been turned out of doors to ripen their canes. The spent hops are here largely employed for plunging the pots in.

Crossing the road to another piece of ground, we found this chiefly occupied with fruit trees, seedling Pelargoniums, which had passed the winter out of doors with slight protection, and a variety of climbers in pots. Mr. Boston now always keeps a considerable number in pots, so as to supply those who require climbers at times unsuitable for the removal of plants in the ground.

The neatness of the place, and the order which everywhere prevails, reflect the highest credit on Mr. Boston's management. As a proof of his consideration for the men, of whom he has about seventy under him, it may be mentioned that he has established a library, from which they are allowed to take books for perusal at their homes.

WHO IS TO BLAME?

In reply to the queries of "C. C. E.," page 207, there is no doubt of some misrepresentations being made from time to time in seed catalogues of new introductions, but as to Laxton's Supreme Pea and Lemaitre's [Lenormand's?] Cauliflower, I am prepared to say that they have in no way been misrepresented.

In the first instance, I have not only seen the representation of the Pea, but grown the Pea itself this season, and I can say it is really grand. Having grown Peas extensively for many years, I have not seen any sort to equal it as a second-crop kind. I gave it a fair trial with Laxton's Prolific and Dickson's Favourite. I did not go to any extreme in preparing the ground for the seed, nothing more than usual, and the three sorts were treated alike. Knowing that Dickson's Favourite and Laxton's Prolific are really two good kinds of Peas, I considered if Laxton's Supreme should excel either of the other two when treated in the same way, it then must be a first-class Pea, and I am glad to say it has turned out so with me. The result was quite the reverse of "C. C. E.'s," as the stem did not exceed 5 feet in height, and began to pod within 10 inches of the ground, and the whole line was completely covered with beautiful, green, well-formed pods, and for many hundreds opened I counted in each pod from nine to fourteen well-formed Peas. I can, therefore, affirm that it is quite equal to the description given of it.

In the second instance, I have not been disappointed with

the Cauliflower, as it has proved itself an invaluable kind with me, for I find that many more plants can be planted in a given space than can be done with the larger-growing kinds; it comes in much sooner, preserves its compactness much longer, and does not suffer so much as the taller kinds do from the weather.

"Who is to blame" in these two instances is rather hard for one to determine, as it not unfrequently happens that the cry may come from where the fault originates, for this reason—many persons are often too fond of giving rather much attention to new introductions of seeds and plants, which ends in disappointment, and then a hasty conclusion is arrived at, that the seeds or plants are worthless and too dear. To those who may be so disappointed I would recommend the old maxim of "Try again." If gardeners were to manifest a reluctance to try new introductions of seeds, &c., as is said by "C. C. E.," they would soon retrograde, and many fine varieties would lie in oblivion.—JOHN BOYLE, *Narrow Water Castle Gardens, Co. Down, Ireland.*

"C. C. E." rather runs down Laxton's Supreme Pea; certainly it attains a greater height than is stated in any catalogue, but taking its bearing qualities and flavour into consideration, it is a very desirable variety. This spring I sowed half a pint of the seed alongside of Veitch's Perfection, Wonderful, Ne Plus Ultra, and other first-class sorts, but taking everything into consideration, it yielded more and lasted longer in gathering than any other variety I grew. I had about thirty-two rows of different kinds across one-half of the garden. Its height did not exceed 4½ feet, but the pods were produced in such profusion, that to keep the haulm from breaking down, my men ran three rows of tar cord on each side. I must confess I never counted fourteen Peas in a pod, but there were from eight to ten or twelve in most of the pods. Everyone who saw it in bearing asked me its name. As for flavour, the first time a dish was gathered for the room table, my employer said, "What Peas had we in to-day, Bowlby?" I said, "Laxton's Supreme." His answer was, "I thought it either was a fresh sort, or else the cook had them prepared in a fresh way." It certainly must prove an acquisition where flavour, colour, and bearing are taken into consideration. It must not be supposed that a Pea will keep to its stated height; ground, manure, climate, and the difference of seasons have all to be considered. As with other new subjects, there will always be found some one to depreciate them, even in the face of competent judges, and after full experiment. I think Messrs. Carter would not willingly impose an article upon the public without giving it a fair trial, or having judgment pronounced in its favour.—JOHN BOWLBY.

I BOUGHT a sealed packet of Laxton's Supreme Pea, and sowed the seed in a part of the garden that was considered the best in all respects; it grew higher than my head (I am 6 feet), and the pods were no larger than those of Ne Plus Ultra. In short, you could not distinguish one from the other, except we fancied Ne Plus Ultra had the finer flavour.—H. A., *Prestwich, Manchester.*

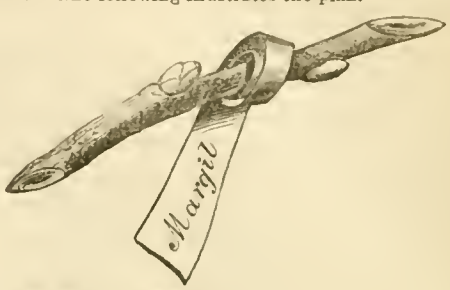
POTATO-GROWING EXTRAORDINARY.

THE Rev. B. Glazebrook, who last year succeeded in growing two crops of Potatoes in the same ground in his garden at Bodmin, fifty miles eastward of Penzance, and not the best aspect—sloping to the north—has this year, by the simple process of intercropping, thus gaining time, succeeded in growing two double crops, a feat probably never before accomplished, if even attempted; whilst no larger breadth of ground was occupied than is usually taken for one crop. The process was the following:—

The first Ash-leaf Kidneys when banked, were intercropped in the furrows with Bread Fruit of middle kind. This double crop was dug *seriatim*, principally in June, banking with the soil the adjoining and forthcoming crop, and their places immediately occupied with late Potatoes. Thus no time was lost. The second double crop is now (September 4th)—a month earlier than last year—being dug, and is a fair average crop, notwithstanding the drought. Mr. Glazebrook has preserved seed and inspection specimens of the whole four products, crops, and intercrops. A row of the first intercrop, 25 feet long produced when weighed 6½ lbs. of Potatoes. A little additional manure was used when the Potatoes were tilled. The above simple process is likely, if properly carried out, to be many a shilling, if not crown, in a cottager's way, with his limited plot of ground. —(*Western Morning News.*)

LABELS FOR FRUIT TREES.

ONE of the most interesting features of fruit-growing is to have the name. One of the simplest and best methods is writing with a common lead pencil on a piece of zinc. We have some which have been in use ten years, and the writing is blacker and plainer than when first done; indeed it can be scarcely traced when first written. A triangular piece is used, and the narrow end coiled once or twice round a branch; as the girth increases the zinc opens. If it do happen to get tight, a moment soon corrects it. The following illustrates the plan.



—(*American Gardener's Monthly.*)

THE LADY-BIRD.

WHILE many conflicting opinions are going the round of the gardening and other papers as to the cause of such myriads of this pretty Coccinella so suddenly visiting our gardens and fields, and whether we are to consider them as enemies to our crops or as enemies to the aphides, I am glad to be able to give some quite conclusive evidence respecting the great good they have done by their visit. Although I have not actually seen the lady-bird eating aphides, those trees which were laden with them were after its appearance suddenly cleared of the destroyers, while other trees which were healthy and free from green fly, were also free from lady-birds. Now, if the aphides were not destroyed by the lady-birds, their sudden disappearance is a mystery. However, I have further evidence in favour of the lady-bird being an aphis destroyer. I had a large old plant of Franciscea angustifolia covered with mealy bug, and after leaving it out of doors for a few hours it was invaded by lady-birds, which cleared off every mealy bug. Of this I am certain, for I saw the lady-birds eating the mealy bugs; and after the bulk of these were consumed, it was curious to see the rapidity with which the lady-birds travelled over every leaf and branch in search of more. Finding none, they gradually left the plant. —THOMAS RECORD, *Hawkhurst.*

NOTES AND GLEANINGS.

IT was stated by one of our contemporaries the week before last that our notice of the late Mr. ROBERT THOMPSON was written by his son. It is but right to that gentleman for us to say that no portion of that notice was either written or dictated by him.

—— AN Irish contemporary has thrown out a suggestion that the ROYAL HORTICULTURAL SOCIETIES OF LONDON AND DUBLIN should unite in holding a Great International Exhibition next year in the latter city. The notion is a praiseworthy one, but we are afraid there are difficulties in the way which will frustrate so good an intention. First of all, there are the physical difficulties of those four hours of sea between Holyhead and Kingstown; the many changes that would necessarily have to take place between such towns as London, Manchester, and even Liverpool, to say nothing of more out-of-the-way localities. There have been attempts to hold such International Exhibitions in Edinburgh, and although there is no break in the railway communication between England and Scotland, these Edinburgh exhibitions are practically Scotch, and only international in name. It would be the same if the London and Dublin Societies were to combine; the result would be virtually an Irish exhibition. However, it is a

matter for exhibitors to determine. If our great nurserymen and amateur exhibitors will take their collections a sea voyage to Dublin, there is no reason why the exhibition should not be held; but in that case the Royal Horticultural Society of Dublin might as well do the thing single-handed. The distance from London to Paris is not nearly so great as from London to Dublin, and the facility for transmission of goods is as great between the one place as the other; yet notwithstanding the attractions of the great Paris Exhibition of 1867, how few English horticulturists took their collections there. We think the Scotch and Irish Societies would confer greater benefits by holding country meetings in various parts of Scotland and Ireland, as the English Royal Horticultural Society is doing in England.

—— At the meeting of the Royal Horticultural Society, to be held on October 5th, the following prizes will be offered—viz., by W. Wilson Saunders, Esq., F.R.S., for collections of Edible and Poisonous Fungi, to be tastefully set up, and, as far as possible, correctly and conspicuously named, £5, £3, and £2.: by Messrs. J. & C. Lee, for the best three bunches of Madresfield Court Black Muscat Grape, £5.: by the Society for the following kinds of Grapes—3 bunches of Chasselas Musqué, £1 and 10*s*.; 3 bunches of Muscat Hamburgh, £1 and 10*s*.; 3 bunches of Frankenthal or Hamburgh, £1 and 10*s*.; 3 bunches of White Muscat of Alexandria, £1 and 10*s*.; 3 bunches of Alicante, £1 and 10*s*.; 3 bunches of any new or recent variety, £1 and 10*s*.; and for the best collection, named, £2 10*s*. The competition for the whole of these prizes is open to all comers.

—— The widow of Mr. Henry C. Ogle, who for many years filled the position of head gardener to the late Earl of Abergavenny, of Eridge Castle, near Tunbridge Wells, is in greatly reduced circumstances. She is at present the lessee of a lodging-house, in a fashionable watering place in Sussex, and unless a sum of money to the amount of nearly £100 be almost immediately forthcoming, she will be compelled to part with her furniture at a sacrifice and with it her only chance of for the future obtaining a living for herself. Messrs. Whitfield & Co., Bankers, Tunbridge Wells, have kindly consented (through their manager) to receive the same. Mr. Cox, Redleaf, Penshurst, Kent, has permitted reference to him as to the truthfulness of the facts.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The manure heap should now be occasionally thrown over and mixed, to bring it into a good state to wheel on the land; if the liquid which runs from it can be directed to a receptacle at hand, and occasionally thrown over the heap, it will be found of great advantage in enriching the manure and hastening decomposition. Trenching must be proceeded with as time will permit. To those who have very light land, and have their Turnips and other crops of the Cabbage tribe affected with clubroot, I would recommend the introduction at this season of some hot newly-slacked lime a few inches below the surface; this, besides being a good manure for such lands, is also an effectual cure for the clubroot. Plant out immediately the main crop of spring *Cabbages*; on the first dry day after planting, fork between the plants; if this be occasionally done there will be no necessity for earthing-up, as the plants, if not put too close together, will grow short and stocky. Attend to the earthing-up of *Celery* likely to be wanted for use soon, keeping it closely soiled, so as to have it well blanched. Keep the late crop well supplied with manure water while growing weather continues. *Cauliflowers* should be looked over frequently, turning down a few leaves over the heart, for these are readily spoiled by frost. Continue to tie-up *Endive* for blanching; it may also be blanched with slates or tiles, doing so saves time, but at this season tying is to be preferred. Provision should be made for protecting a quantity of *Dwarf Kidney Beans* from frost. Plant a lot of Brown Dutch or Bath Cos *Lettuce* where the plants can be protected by frames, for spring use. Transplant winter *Onions* on a warm border; let them be put in rather thickly, to allow for pulling out in the spring; of course a portion may be left in the seed bed if required, but it is preferable to transplant the whole.

FRUIT GARDEN.

Pay attention to the gathering of Apples and Pears; the late high winds have made great havoc amongst them. Espaliers, dwarf standards, and, indeed, any kind of fruit trees which exhibit more tendency to produce useless wood than that likely to furnish fruit, should be root-pruned as early in the autumn as convenient, cutting out any useless shoots at the same time, in order to expose as freely as possible to light and air the wood expected to bear fruit. Continue to dress old Strawberry beds with rich decomposed manure; it is better done at this season than in the spring. If time serve, it will be very beneficial to Peach trees to go over them and cut out the shoots which have borne fruit, but have not a terminal wood shoot. Those remaining will be benefited by the thinning, as they cannot be too open at this season. We must now begin to think of making preparations for filling up vacancies on the walls with young trees, and, perhaps, in some cases, judicious transplanting may be considered advisable. In either case the sites must be properly prepared with fresh maiden soil; if the borders have been properly formed with regard to drainage and a porous bottom, but little preparation, beyond removing a considerable portion of the old soil and supplying its place with new, will be required.

FLOWER GARDEN.

The removal of decayed flower stems, dead leaves, or anything which injures or disfigures a scene, has a surprising effect in making this department cheerful and attractive. Sweeping, rolling, &c., should be attended to in the morning, that the ground may have a tidy appearance when visited by the family. Repair any damages occasioned by the late high winds, by resticking those plants which have been blown over, and nailing-up shoots of climbers which have become detached from the walls; nothing looks so untidy as these when blown about by the wind. As frosty nights may now be expected, scarce plants which it may be desirable to secure before they are injured, should be taken up and potted at once, or carefully covered when there is the least chance of injury. Secure a good stock of cuttings of variegated Pelargoniums before the plants are injured by frost, for although these root more freely in spring than at present, such varieties as Golden Chain and Mountain of Light grow so slowly, that spring-rooted cuttings make but very poor plants by turning-out time; hence it is desirable to gain size even at the expense of the loss of a few cuttings. That cuttings taken from plants growing in the open ground are liable to damp-off in a moist, warm place is well known, and the variegated Pelargoniums are, perhaps, more so than most other plants; but persons who can command a gentle bottom heat, without keeping the atmosphere warm and moist, will experience no difficulty in striking them now. The old plants are, however, well worth wintering wherever room can be found, for these go much further at planting-out time, and cover the beds sooner with foliage and flowers than either autumn or spring-rooted cuttings; hence they should be carefully guarded from frost until the beauty of the garden is destroyed, when they should be taken up, potted, and stored for the winter in a cool dry house. Continue to put in cuttings of Hollyhocks, as these can be obtained, until there is an ample stock of rooted plants, and do not allow those that were rooted early in the season to suffer from want of pot room. Cut off the flower stems of herbaceous plants as soon as they become shabby.

GREENHOUSE AND CONSERVATORY.

Keep New Holland plants, which have been placed under glass, cool and airy, and avoid crowding, especially in the case of plants which are in a growing state; but everything must be allowed sufficient space, so that the foliage may be fairly exposed to light and air. Rather than crowd specimens together, some of the least valuable should be thrown away. To do justice to a mixed collection of plants in one house is a difficulty which too many have to contend against, for to have in the same house plants which require a temperature of 40° as a minimum, and others, for instance, Heaths, for which 40° should be the maximum temperature, with one set demanding a thorough current of air at all times, and others dying even if exposed to it for a short time, is a state of things rather puzzling to young gardeners. Polygalas, Boronias, Croweas, Dracophyllums, Pimeleas, Leschenaultias, and Gompholobiums do not like to be much exposed to cold currents at any time, and therefore they must be protected as much as possible, of course bearing in mind that over-nursing is as bad as no nursing at all. Give each plant all the room you can spare for it, and above all take care that the plant, the pot, and every part about it are perfectly clean before the plant is taken into the house. Look sharply after mildew upon Heaths, as it is sometimes very troublesome upon plants that have been growing freely in a shady situation in the open air, and are in

a rather soft state when taken in-doors; apply sulphur freely on the first appearance of the enemy.

COLD PITS.

Plants which have made their season's growth should be freely exposed to sun and air on every favourable opportunity, in order to ripen the wood well; but those still in free growth should be encouraged by every possible means while fine weather continues, keeping them rather close, guarding them carefully from cold winds, and giving a liberal supply of water at the root. If any plant requires more pot-room, let it be shifted as early as convenient, keeping the atmosphere rather moist, and watering very cautiously for some time afterwards, until the roots take hold of the fresh soil.—W. KEANE.

DOINGS OF THE LAST WEEK.

Improving Cropping Ground.—Now and further on in the season are good times for all such work. All ground that is at liberty, if deep enough, will be improved by trenching and mixing the different layers. If the soil is rather light it will be best left rough on the level; if stiff, leave it in rough ridges, that the frost and even mild air may have free access, as frost is one of the best and cheapest of pulverisers. If the ground is thin and the subsoil bad, but little of the latter should be added every season, but it should be broken up at bottom and left there, and thus it will be gradually improved. Very light sandy soil will be greatly improved both by clay and chalk. The former will render it more cohesive; the latter will make it more retentive of moisture. Quick or caustic lime is chiefly useful, when there is much rough insoluble organic matter in the soil that needs to be decomposed. Very stiff soil is greatly benefited by sand, by lime and chalk, and by burning a portion of the clay and using it as a dressing. As a mere lightener of the soil chalk is as good as lime, and merely as a mechanical agent it thus has a great effect on the produce and the ease of cultivating. When we used it with good results we have often been surprised how soon it would sink away from the surface and find its place in deeper layers; hence the importance of trenching, and mixing the layers. We have known garden soil resting on clay so stiff as to be unworkable in damp weather, and yet at from 15 to 30 feet from the surface there was a deposit of chalk, which by means of a shaft could have been raised in quantities to the surface, and would have greatly ameliorated the texture of the soil and rendered it much easier to work. When a stiff soil rests on clay it will be greatly improved by burning a piece of the subsoil every year, using prunings and rubbish for the purpose. When fairly set going but little fuel is necessary. Clay when burnt is as good and even a better lightener than sand, and in our experience does not so soon sink away from the surface. Many stems and weeds, hardly fit for the charring-heap, might be used for this purpose; but half-burned, half-charred rubbish and earth are among the best improvers of stiff soils, and come wrong to no soil if used moderately. When clay is used for light soils an inch, or from that to 2 inches, will generally be enough, and that if possible should be applied dry and in a finely-divided condition. We have known it used more freely and in a damp close condition, and for years it seemed to do harm rather than good, as whenever roots came in contact with the clay, they turned away from it and would die sooner than pierce it: hence the importance of using it in a finely-divided state.

In some cases clay may be used with great advantage as a substratum for securing a cool moist bottom. We knew a pretty flower garden on sandy soil, with a subsoil of open gravel and porous rock. In a dry season no watering would keep the plants moist, and the more water was given the more were the nutritive properties of the soil washed away, unless, indeed, manure water was used. The only chance in hot dry seasons was a copious rich mulching at the surface, and this was out of the question, as the owners liked to see the soil present a dressed fine surface, almost as smooth and fine as the surface of a dining-table—a degree of fine keeping which we always look upon as worse than waste of time and labour, as the plants have not the same chance as in soil with a rougher, more open surface. Clay was not mixed with the soil, but the soil of the beds, which were not large, was turned out between 18 and 24 inches deep, and 2 or 3 inches of clay were firmly hammered at the bottom, some rough rubble placed over it, and then the soil, and the plants have required not nearly the same amount of care and watching since. The firm damp bottom in such a case proved of great advantage to them.

KITCHEN GARDEN.

Much of the work was of a routine nature, as earthing-up Celery in the fine, dry days, planting out Cabbages, pricking out the same to be lifted as the ground becomes ready for them, planting out some of the most forward Cauliflowers in patches for hand-lights, to come into use in spring, placing nine in a square, to be thinned afterwards to four or five, and not giving them the handlights for some time yet. Besides digging the ground and firming the surface, we strewed a little drift sand on each square patch, as snails and slugs do not like to crawl over it, and the crop never looks so regular and well after it has had several fillings-up, owing to deaths and depredations. Scattered some fine ashes among the last-sown Cauliflowers, Lettuces, Radishes, &c., which will help to keep intruders at bay until washed off by the next rains, and even then wood ashes, from their saline properties, will help to keep the ground free of slugs, snails, and worms. The chief work, however, has been hoeing and forking among all crops to keep down *weeds*, and to prevent the surface caking after the rains. Where not a vestige of a weed was to be seen a short time ago, the rains soon presented us with a surface of tiny green weeds that would soon become larger if left alone. We noticed in a corner quite a mass of Groundsel, some 2 or 3 inches in height—hundreds, if not thousands, of them, the progeny of a single plant that was unnoticed before it arrived at the seeding state. How far the seeds from that plant extended it would be difficult to say. The other Sunday our coat was whitened with Thistle down that must have come from some little distance. There is no hope of keeping down weeds except by cutting them up as soon as they appear, and leaving the sun to scorch them up. It is a great waste of time and labour when other utensils besides the hoe must be brought into operation. Frequently, however, the stress of work is such, that the weeds cannot be attended to in time, and pulling up, or hand-weeding, and raking up must be resorted to at a sad outlay of time and labour. We cannot always practise what we teach, but the easiest and best way of keeping a place clean is never to let weeds grow above 1 or at most 2 inches in height.

Grubs on Cabbages.—As yet we have nearly escaped these, so destructive to fresh-planted Cabbages, but they have been very prevalent in this neighbourhood during the present season. Some tell us that they lose half their plants in a night; others that they have filled up their plantation three or four times, and still the plants go at the rate of from twenty to thirty per cent. in a night. The only sure remedy is to examine the cut-over plant, collect the fat lumpy grubs at the roots a little below the surface, and make short work with them. Watering with soot water, lime water, soapsuds, &c., will help to keep them away, and so will smearing the stems with soot and lime previously to planting, as the plants are generally cut-over close to the roots, and it is not uncommon to find three or four of these grubs at one root. We have not found such surface applications as soot or lime, or even a sprinkling of tar between the rows, of much benefit; but frequently stirring the ground annoys the grub, and strong bad scents seem to deter the perfect winged insect from depositing its eggs in the soil. A slight sprinkling of tar, even in winter, seems to help to keep them away. Putting baits of sweet Carrots, Turnips, and even split stems of Cabbages, will help, but only a little, to keep the visitors under, chiefly because of all baits nothing is so agreeable to them as a young Cabbage plant, and especially when the plant is in a languid state from being recently dibbled out. Singularly enough, we have seldom known these grubs attack the young plants in the seed bed, and when they have done so, a watering of strong lime and soot water has generally dislodged them. Neither do they so often attack plants which are tolerably well established. We have been recommended to hunt for them at night with a lanthorn, but though others may be more fortunate, we never found one, partly, no doubt, because though the grubs are large, generally from 1 to 1½ inch in length, they are of a whitish drab tint, and thus resemble the colour of most soils, and partly because we have doubts if they ever show themselves much at the surface, as during the whole of their long existence they seldom appear above ground, except in the winged state, and even then do most of their work at night, instead of during the day.

Besides catching the grubs as stated above, but too often after they had done the mischief, we have in extreme cases resorted to the following plan, as even the largest bed of seedlings would soon be exhausted in filling up, when the grubs had

taken possession of the ground. We have simply let the plantation alone, killing the grubs as they killed the plants, and inserted Lettuces, spare Broccoli, Cauliflowers, &c., for a time in their places, to entice the grubs. We have then carefully turned over a piece of ground, and examined it pretty carefully to the depth of 4 inches, looking after grubs. We then added a dressing of soot and lime, and some very rotten dung, and pointed and stirred all together for a depth of 3 inches, and in this turned out the young Cabbage plants, 3 or 4 inches apart; here they grew vigorously for two or three weeks. Meanwhile, after all the Cabbage ground had been well examined, and slightly turned over repeatedly, shallow drills were drawn, the Cabbages turned out with balls by the help of a trowel, and planted just deep enough to cover the roots, and a little hillock of soot and lime was placed round each plant—that is, fully as much as could be held between the thumb and two fingers. We have then seldom lost a plant. The operation is based on what little we have observed of the habits and tastes of the grub.

It may be interesting to some to state that the worst form of Cabbage grub is the larva of the cockchafer, which insect, unlike many others, is destructive in its winged as well as in its grub state, feeding as a beetle voraciously on the leaves of trees, &c., at night. It deposits its whitish eggs in the soil, and these soon hatch into grubs, which, as stated above, are about 1½ inch in length, have a whitish buff skin, and seem little except a mass of fat beneath it. The larvæ of the larger crane flies resemble this grub considerably, but generally they have no feet. They are equally destructive beneath the surface to the roots and stems of vegetation. But for crows, blackbirds, and thrushes, who pounce on these grubs greedily, our pastures would often resemble a bare turned-up field. The worst evil is that the larvæ of the cockchafer exist in the grub state several years, some naturalists say five, and then they go down to the depth of 4 or 5 feet, change into the chrysalis state, and emerge next spring as the perfect beetle. The only time in which they do not act antagonistically to our labours is whilst quiescent in the chrysalis state. On the other hand, the daddy-longlegs is perfectly innocent in its winged state, living merely, it would seem, for the purpose of depositing its eggs. We are more surprised at the abundance of the grubs of the cockchafer than of those of the daddy-longlegs, as, though others have seen myriads of cockchafers in the evenings flying about in a seemingly blind stupid way, we have never seen many of them; whilst of the daddy-longlegs we often could have swept up a peck from flagstones in a cool morning in autumn.

But for the unpleasant scent in a garden, we have reason to believe that rags steeped in melted sulphur and in tar, suspended from a stick or string, would deter the females from depositing eggs, and that would be going to the fountain head for a remedy.

By all accounts there will be some difficulty in making an early plantation of Cabbages this season. We are so apt to jump at conclusions as to cause and effect, or we would say that a sprinkling of tar over our Celery ground before it was trenched across preparatory for Onions, might be a reason why not an Onion was touched by any sort of grub, and why the Cabbages succeeding them are unmeddled with. We have had no chance of trying it, but some correspondents may be right in stating that weak ammoniacal liquor from the gas works will keep all such grubs away. For years we have found that when almost everything in a garden was left untouched, the young planted-out Cabbages at this season were sure to be attacked. We know of numbers of cases in which cottage gardeners have exhausted their seed beds in filling up, and still have almost empty ground. If, therefore, any of our readers can supplement the above remarks with a better mode of cure or prevention, they will confer a public benefit, and more especially on the holders of small gardens, to whom an early Cabbage is of importance.

FRUIT GARDEN.

Attend to preparing for planting, gathering fruit, &c., as detailed in previous notices. In cold, stiff soils above clay, and that again above chalk, we find that fruit is a week or two later than it is on darker and lighter soils. The exposure and the altitude have also an effect in these matters. In a sunny season we have found Strawberries eight days earlier on a bank steeply sloping to the south, than immediately in front of the bank on the level, whilst in a cloudy, dull season there would scarcely be any difference. Little as yet has been done as respects the colour of the soil, and husbanding and storing the heat supplied by the sun in securing early productions. Were Strawberries and even cordons of trees trained within a foot of a dark firm surface, and then protection given to prevent the radiation of heat at night, fruit could be greatly forwarded, provided we could make sure of sun heat, and could keep it when obtained. In dull weather the darker surface would be of no advantage.

We gave different manure waters, as soot, cow dung, &c., to Strawberry plants in pots, as it is yet rather early to begin to ripen off the buds, especially in our case. To save pots, we shall plant out a lot of potted runners, and raise them in the spring when wanted. Gathered fruit in fine days. Low bushes and pyramids have suffered but little from the tempestuous wind.

ORNAMENTAL DEPARTMENT.

The few sunny days have wrought a charm in the flower beds; but for depredators interfering with lines of Lobelia and Verbena, and the winds that still prevail, sending down the leaves from the trees, we would seem to have a second summer, Not the cold, but the high winds, have made the foliage of trees brown and rusty unusually early, merely from the branches and leaves being brought so rudely in contact with each other. Several parts of the grounds have needed sweeping every day, and that for a month or two will be a ceaseless operation. The greatest drawback, however, is, that the finest floral display is deprived of much of its beauty when surrounded by falling and driving leaves. Walks treated as described some time ago have needed nothing since—scarcely even rolling after rain, as they are smooth enough without it.

Proceeded with sheltering the more tender plants in pots, making cuttings of bedding plants which, with the exception of Calceolarias, we hope soon to finish, but the Calceolarias we shall leave until the end of October. With all our Tricolor Pelargoniums, &c., nothing will take the place of the yellow Calceolaria; and this season, dry weather and all, they have done well, and though shaken by the late tempests, they are now coming into full bloom again. We have put in some more cuttings of Verbenas, and placed them in a frame where they would have the slightest bottom heat; all else as yet has had no help but a cold pit or the open air. Boxes when to be had are preferable to pots. Last season we struck lots of Scarlet Pelargoniums, &c., in 60-sized or 4-inch pots, from six to nine cuttings in a pot, and they stood and turned out well. With us cuttings or plants in single pots for bedding are not to be thought of in winter; all must stand thickly, from 1 to 2 inches apart, until the spring. Proceeded with repotting Pelargoniums, Primulas, Cinerarias, Coleuses, Ferns, &c. We have several times noticed the mode of repotting old Pelargoniums, reducing the roots, and placing them in smaller pots, when the cut-in heads have broken into fresh growth.—R. F.

COVENT GARDEN MARKET.—September 29.

We have had a very poor attendance of buyers during the past week, and business generally has declined. There have been large arrivals of Grapes from Portugal and Spain; they are now offered in good condition at very low prices, the best not realising above 1s. per lb. Hothouse Grapes are also plentiful. Peaches and Nectarines are nearly over.

TRADE CATALOGUES RECEIVED.

Louis Van Houtte, Ghent, Belgium.—*Catalogue of Azaleas, Camellias, Rhododendrons, Liliums, &c.*

Gautreau père, Brie Comte-Robert, Seine-et-Marne.—*Catalogue des Meilleures varietés de Roses.*

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Roses and Hollyhocks.*

William Masters, Exotic and Vanxhall Nurseries, Canterbury.—*Hortus Durovernensis, a Catalogue of Useful and Ornamental Plants, Trees, and Shrubs.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Notice to Quit Service (*G. S.*).—As you receive your wages weekly, you are not entitled to a month's notice.

Exotic Flowering and Fine-foliaged Plants (*Secretary*).—An exotic Fern ought not to be exhibited in a class so restricted. A species of the genus Begonia might be exhibited in the class, for the restrictive words "excluding florist's flowers," have not yet been applied even to varieties of the Begonia.

Bulbs from South America (*Rev. J. W. B.*).—We believe them to be from the stem of Dioscorea alata. If so, the root is often 3 feet long and weighs 30 lbs. It is not even half-hardy here. We did not intend to be curt in our former reply, but to have noticed the statement at all would needlessly arouse attention; and even supposing our correspondent's conclusion correct, the error in chronology would no more effect the volume's basis of truth than its error in astronomy.

Sulphate of Iron (*S. S.*).—This, commonly called green vitriol, is only beneficial as a manure when applied to soils containing a large proportion of chalk, and then only for some crops. It is useful to mix with fermenting stable manure, to detain, or fix, as it is termed, the ammonia.

Garden Produce (*W. B.*).—You must see or correspond with some of the salesmen in Covent Garden Market. A half-sieve contains three and a half imperial gallons.

Painting Glass for Shade (*T.*).—We have tried painting the glass with a thin coat of white lead paint, and we find it answers admirably for a fernery. The glass should be thoroughly dry, and as the paint is put on dash a painter's dust brush upon it perpendicularly, so as to give it a frosted appearance. Our paint was put on outside. We have no experience of it inside, and fear it would peel off from the continual condensation of moisture on the glass. The painting would not stop the leakage. If it be from the laps they may be puttied up, but we are of opinion that the putty is off in many places. All that is loose should be replaced after giving a coat of paint. Only one coat of paint must be given the glass, and we would not paint until next March.

Limnanthes Douglasii for Spring Blooming (*T., No. 2*).—The summer-sown plants now in flower are not likely to survive the winter. A sowing ought to have been made in the middle of September, but you may yet sow in the same bed, planting out the present occupants. If these fail the seedlings may survive, and if so will flower in May. It is one of the best annuals for spring gardening.

Wintering Fig Trees in Pots (*Idem*).—The trees in pots will do well during the winter in a dry cellar cold enough to prevent growth. The soil ought to be kept dry. It is enough to merely exclude frost. Remove them to the orchard house in April.

Golden Feather Pyrethrum (*Idem*).—It is quite hardy, and may be left in the beds all winter. In wet soils it is liable to make late growths, and suffer from severe weather. A sandy well-drained soil is best. (*An Amateur*).—If your soil is not very wet, move the plants this autumn, with good balls; plant them where wanted, and they will be better than those wintered in frames, and planted out in April. The flower stems ought to be removed as they appear.

Cuttings of Imperial Blue Pansy (*An Amateur*).—The cuttings inserted in July will now be well rooted, and ought at once to be planted out where they are to bloom, which will be a better position than under a north wall. If not planted now, they should be put in a bed in an open sunny situation, and be moved with balls to their blooming quarters in March.

Sowing Virginian Stock for Spring Blooming (*Idem*).—To have it in flower early in spring it should be sown by the middle of September, but it may yet be sown, and will flower at the end of April or in May, according to the earliness or lateness of the spring.

Planting Bulbs in the Same Beds Successively (*Idem*).—You may plant all kinds of bulbs in the beds they previously occupied. It is unnecessary to take out any of the soil; give a liberal dressing of leaf soil and manure, and mix it well with the ground.

Wintering Bedding Pelargoniums (*Idem*).—Except in mild winters they cannot be wintered in unprotected cold frames. The sides of the frames ought to be banked-up with ashes to exclude frost, and in addition to a covering of mats a covering of dry straw in very severe weather should be placed over the lights. This ought to remain day and night till a general thaw. The plants will not be injured by the darkness as long as they do not grow. In mild weather give all the air possible, and do not water nor allow them to have rain. The plants ought to be potted in dry soil, but a better plan is to place them in the frame, cover their roots with dry soil, and not water before March. Pick off all yellow and dead leaves as they appear, and any shoots that decay cut off close to the living wood but not into it. Select a dry and warm situation.—G. A.

Transplanting Roses (*C. R. H.*).—The best time to take them up and replant will be the beginning of November. Efficient drainage is essential, but mildew is more a consequence of want of water in dry weather than anything else. The ground being clayey we would trench it, working in a liberal quantity of manure and ashes. After planting, mulch the surface with littery manure.

Propagating Roses by Cuttings (*C. T.*).—The best time to strike Rose cuttings out of doors is the end of September, but now will answer very well. They should be placed in a sheltered situation, as a north border, and if you use a soil composed of equal parts of sandy loam, leaf mould, and sand well mixed together, it could not be better. Six inches thick will be sufficient.

Roses of the Last Two Years.—"'*Devoniensis*' wishes me to give my opinion of recently imported Roses, and especially of those of the last two years. It has been a bad season for novelties on weak stocks; indeed it has been a trying season. I do not like to say much about new Roses till I have them upon strong stocks, and have had two or three seasons' trial of them, because I have known Roses that I now appreciate do badly when on weak stocks. The best of later years, and good, are:—Alfred Colomb, Marie Baumann, Baroness Rothschild, Lady Suffield, Felix Genero, and Annie Wood, new out and beautiful; and the two ornamental Roses, Dr. Jamain and Baronne de Maynard. The whole of the above I can recommend. As ornamental Roses (both *presque pleine*). I will name as good growers, handsome, and free bloomers, Madame Barriott and President Willermoz. The plants (two each), of these were weak and did not grow well, but they may be pronounced promising—namely, François Treyve, Monsieur Nomao, and Mdlle. Marie Rady. The last, I should say, would on strong stocks be superior, but not, I fear, very distinct. The following I have rejected—namely, Charles Verdier, not a free bloomer; Charles Rouillard, bad colour and flimsy—it is not so good as Comte de Nanteuil or Felix Genero; Paul Verdier, beautiful, but not a late bloomer; Madame Morean, much given to mildew; and Mdlle. Jeanne Marix, a hard opener, and not a late bloomer. Reine du Midi is also a fine Rose, but like La Reine, its parent, it is as hard as a cricket ball. I shall keep it on one year more, though I had only one good bloom from ten plants. Adrienne Christophle is beautiful and distinct. Clotilde Rolland I saw in bud at Blandford; it promised to be good. I saw the Duke of Edinburgh and Baron Haussmann in Mr. Keynes's boxes at Blandford; they were good, and his best novelties. The first, I shall buy. I have increased my stock of Fisher Holmes; it is fine, and better than the Duke of Wellington and Horace Vernet. Horace Vernet and Thorin have not yet been full enough.—W. F. Radclyffe."

Blairii Rose not Blooming (*A. Roche*).—It is a fine Hybrid China, especially as a pillar Rose. The reason it does not bloom is, you prune it too closely. All that is required is to thin out the old shoots, and shorten a little those to be retained.

Value of Turf and Cutting (*A. G.*).—Good turf may be had in most places at 3*d.* per square yard, or 4*d.* if cut and loaded, but the price varies with the locality. For cutting and laying 1½*d.* is the usual price per square yard, and for cutting and loading only ½*d.* per square yard. Two men will cut from 150 to 200 square yards per day, but the ground makes a difference. Sometimes they do more, often less. For what you describe the price per hundred ought not to exceed 10*s.* for the turf and cutting. We have known, however, 6*d.* per yard paid.

Plants for Pot Culture (*C. M.*).—Lilium candidum flore-pleno, L. tigrinum, and Dielytra spectabilis are suitable for pot culture. They succeed equally well in pots or planted out. Dielytra spectabilis is one of the best of plants for a greenhouse or gentle forcing.

Wintering Arctotis reptans (*Tig*).—It should be kept near the glass in a well-ventilated house from which frost is excluded. It ought to be potted in poor sandy loam and a little peat, have good drainage, and no more water than is necessary to keep the plant alive. Cuttings struck in August are more easily wintered than older plants or those taken up from the open ground and potted. They ought to be established in pots before winter.

Amy Hogg Pelargonium (*Idem*).—It succeeds well in a bed, and, like all the Nosegays, does tolerably well in smoky gardens.

Propagating Golden Arabis (*Idem*).—We presume yours is the smooth glossy-leaved kind, Arabis lucida variegata. In some soils it is very slow-growing, but with us in well-drained rather strong soil it succeeds, but not nearly so well as the others; and the best plants we have seen of it were grown on a gravelly subsoil overlaid by about 15 inches of sandy loam. Leaf soil was used for enriching the ground, and the plants were propagated in autumn by division, any unrooted divisions being placed in sandy soil under a hand-light. We prefer taking cuttings or crowns, with or without roots, in August, and insert them in sandy soil under a hand-glass, keeping them moist, close, and shaded from bright sun, and admitting air after they begin to grow. The plants are fit to plant out in autumn. March is likewise a good time for dividing the plants, and putting in rootless divisions under hand-glasses. Side by side with the other variegated Arabises it will in some places only drag on a miserable existence, whilst the others grow only too rapidly.

Removing a Wellingtonia (*Constant Reader*).—Transplanting this tree is attended with great uncertainty after the specimen has been two years or more in one place, and as yours has been six years where it is, we cannot promise success; but from inquiries we have made, it would appear that April or early in September are the best times. Under present circumstances, therefore, we would advise you to let the tree remain till late in spring. An experienced planter, whom we consulted about removing trees and shrubs, stated that in his opinion the Wellingtonia is about the worst to manage, with the exception of Evergreen Oaks. We have always preferred small plants of both when we have had to plant any.

Neglected Vine (*Anxious*).—The Grape is too young to decide, but it looks like a White Muscadine or Sweetwater, either of which will answer in the position and circumstances. As the Vine produces so much wood, thin it out well, leaving enough of the strongest wood, and let that be well ripened for next season's bearing. We do not see, from what you say, any reason for cutting the Vine down. Better try it another year, and then if it fail you could plant afresh.

GRAFTING VINES (*J. W.*).—Graft the Vines by all means; all the White kinds will do well on them, such as Muscats and Foster's White Seedling.

VINE LEAVES SPOTTED (*Mrs. Heathcote*).—The Vine leaves are blotched and scalded. The remedy is either to give air all night at the top of the house, or to give air early in the morning before the sun strikes on the house.

VINE BORDER FERMENTING (*An Amateur*).—You must not plant Vines until the heat of the soil, arising from the turf fermenting, fall to 75° or 80°. Watering such turfy matter, unless you inundate it, would be of questionable benefit. Better turn part of the material out until it cool.

FRUITING VINES IN POTS (*Reader*).—Between repotting now and repotting next March, there is no comparison; repot at once by all means, merely disentangling the outside roots a little, and potting firmly. If the Vines are in good-sized pots—say 15 inches or more in diameter, we would remove the surface soil carefully, replace it with rich compost, and not repot at all. We would even place a rim on the pot in preference to repotting. We do not think that you need despair of the Frontignan Vine.

VINES, STRAWBERRIES, &c. (*A Subscriber*).—If you refer to our advertising columns you will see where they can be obtained. It would be unfair for us to select tradesmen. Messrs. Webber, Covent Garden Market, could give you information relative to the sale of fruit.

FRONTIGNAN GRAPES SHANKING (*Reader*).—Frontignan Grapes are more liable to shank than most others, and occasionally shanking appears in its worst form—viz, the main stalk of the bunch withering. We have not noticed the peculiarities you name when the Vines are grown in a heated border; the foliage does not brown, nor do the Grapes shank. We think the Frontignan Vine requires a warmer, drier, and poorer soil than many other varieties; a large proportion of the soil of the border ought to be stones so as to imitate as nearly as possible the soil required by all Vines, and especially this class of them—namely, a free, open soil, and warm, stony, or rocky ground. In our climate we have not sufficient heat to ripen the wood properly, and the roots in outside borders have not the warmth necessary for a healthy action. It is well to encourage more foliage than we would otherwise do, and by that means keep up root action; but the Vine ought to have as great a temperature for its roots as its branches.

GRAFTING VINES (*A part Subscriber*).—To all your questions we answer No.

SEEDLING PEAR (*W. T. C.*).—Unfortunately the Pears were so bruised and decayed we could not form a correct judgment on them. We found nutsinted by the accompanying decay a little bit which was very nice, but not sufficient to form a decided opinion.

SHOW GOOSEBERRIES (*An Operative*).—Three of the best of each colour are—*Red:* Guido, London, and Hopley's Companion. *White:* Sheba's Queen, Tallyho, and Wandering Girl. *Green:* Conquering Hero, Thumper, and Wistaston Hero. *Yellow:* Husbandman, Broom Girl, and Marigold. If you wish for size only, then London, Thumper, Hero of the Nile, and Leader. They should have a situation not shaded by trees or buildings. The best soil is a rather strong loam, and if from fresh turf it could not be better. The ground ought to be trenched 2 feet deep. Nothing is better than stable manure, or that of horses, cows, or pigs well reduced; it should be applied in autumn before planting, mixing it well with the soil.

TWIN CUCUMBERS (*G. R. C. C.*).—A fine pair, but we have seen the same occurrence several times. The cause is the union of two ovaries.

PLANTING MUSHROOM SPAWN—STRAWBERRIES (*The Hermitage*).—Your planting the 2-inch-square pieces of Mushroom spawn in a Cucumber bed will succeed according to the state of the bed. Placing the spawn 3 inches from the surface is all right enough if that distance brings you near the dung of the bed. As stated lately, we have planted spawn in the open ground and had fair success, but if we had used the Cucumber bed after the Cucumbers were gone, we would have taken off the soil, turned up the dung a little, beat it down, inserted the spawn at double the distance you have done, covered with 2 inches of soil, and beat down, and if fresh all the better. If there were a little heat left in the bed we should expect to gather in two months. If the soil were somewhat damp, little or no watering would be needed in winter. The ground for your first-class Strawberries we would trench and manure heavily, incorporating the manure with the soil. Turn out the strong plants in rows 15 inches apart, and 2 feet from row to row, and mulch the ground after planting.

HEATING A CONSERVATORY FROM A KITCHEN BOILER (*T. H. T.*).—There will be no difficulty in taking a side flow and return pipe to heat your conservatory, situated as it is, the kitchen boiler now supplying hot water to the top of the house. Of course, the more piping you heat the greater will be the demand on the boiler, but there will be no likelihood of a deficiency of heat at the top of the mansion. With plenty of fire and command in the boiler, you might take pipes over every separate storey if you liked. At first you may have to curtail the flow to the top of the mansion to make the water flow freely into the pipes in the conservatory, but that is not often required. Hot water is sometimes skittish and peculiar. We have had half a dozen pipes proceeding from the same level in an open cistern, and some of these would not take their right quantity of heat unless some more fortunate pipes were plugged a little, so as to make the flow all over more equal. As to your proposed house and pit, more especially as you mean to plant Vines, and these houses are to be lean-to's, we would advise you to make the height at back 10 feet instead of 8 feet, and have them from 5 to 6 feet in front, and 10 feet in width. This will enable you to have a platform on each side of a path down the middle of the plant house, and the same with one or two pits in the other, and building all above ground will give you most pleasure. For such a house, hot water would be best, but flues would do very well. It would, however, be best to have a flue for each house. In the propagating part take the flue round the house under the floor level, so as to be in the centre of the pit, above which have a chamber covered over, and slides in the chamber to let the heat into the air of the house. With one pit and the flue exposed on the other side, you would not need these hot-air openings. The best trees we know of for the seaside are the Pinus Pinaster, the Evergreen Oak, and the Maple; and the best climbers the Virginian Creeper, Ivy, and Clematis.

HEATING A GREENHOUSE (*Heron*).—The proposed arrangements will answer if your Ferns are not tender, and you do not wish your warm greenhouse to be above from 45° to 50° in severe weather. The piping in the cool greenhouse will enable you to exclude frost in severe weather, and to keep the house at from 34° to 40°. You will perceive that you will only have one flow and one return through the Fern house, and when all the pipes are at work, the return will be rather cool before the water reaches there. We approve of the stoppage at H, between the two houses, but to make sure we would recommend you to have, by a T-joint, two flows in the Fern house as far as the partition, and if you wish for a good heat in the warm greenhouse, we would have two flows and one return as far as H. For your purpose a small conical or saddle-back boiler would be best. The terminal saddle-back is better than the common one. A boiler costing from 50*s.* to 60*s.* ought to suit your purpose.

ARNOTT'S STOVE (*Constant Subscriber*).—A moveable iron stove with a square top for water, would best suit your purpose—say, a stove 1 foot square, 2 feet high, with fire-brick round the fireplace inside. The square top will do for a vessel of water. A small brick stove would answer better, but then it would be fixed. See what was stated to correspondents lately as to smoke-pipes and their position. You might have a brick stove fed from the outside like the furnace for a flue, but only a smoke-pipe from it instead of a flue. Much has lately been said on regulating draught from the ash-pit door.

PLANT CASE (*I. D.*).—We have no doubt that you would succeed as well with the larger case as with the smaller one, and be as successful with cuttings as you have been with seeds. There will be no doubt of your succeeding with cuttings sent by post, as advertised by dealers in our columns; the post has an advantage in quickness of transit. Any small Ferns, as the Adiantums or Maiden-hair, and the smaller of the hardy Ferns, will do admirably in such a case, and so would small plants of Coleus, but though they will succeed separately, they will not succeed so well together, as the moist atmosphere that would suit the Ferns will be apt to damp the Coleuses, or cause them to grow too freely. A somewhat dry atmosphere, and a temperature of from 55° to 60° suits them best in winter, when it is desirable to keep them in little space. They grow freely enough in spring and summer, but in a close moist atmosphere and a temperature of from 45° to 50° in winter they will damp off to a certainty. Dryness is their safety in a low temperature. You can have covers for Vols. XV. and XVI., free by post, if you enclose 2*s.* 6*d.* in postage stamps with your direction.

ASPARAGUS NOT SUCCEEDING (*A Subscriber*).—We think the failure is entirely owing to the soapy condition of the soil about the crowns, combined with heavy dressings of salt, which tend to make the surface soil still more moist. We would remove the surface soil down to the crowns when the haulm becomes yellow, and replace it with a compost of sandy loam, leaf soil, and river or sharp sand in equal parts, not covering deeper than 3 inches, and then putting on 3 inches of manure, not covering it with soil, as is usually done. In spring point over the beds lightly, and sow the seed early in April, three rows in a bed, and thin out the seedlings in June to 6 inches apart. Dress with salt in March, but not next year. 1 lb. per square yard is sufficient.

CONIFERS FOR A LAWN (*Idem*).—You confine us to dwarf kinds, none to exceed 10 feet in height when full grown. You may plant the following:—Abies rubra cærulea, A. elegans; Juniperus macrocarpa, J. communis pendula; Retinospora ericoides, Taxus adpressa, and Thuja plicata caucasica.

FRUIT-GROWING FOR PROFIT (*W. M.*).—Growing Peaches in the open air in this country, however good the crops realised, seldom pays. Good winter Pears are far more profitable; or, why not cover your wall with glass, and then Peaches would in your climate come in pretty early, and secure a good price before the great glut of the season could compete with them?

CHARCOAL FOR POTTING (*A. B. C.*).—Any wood answers well. The shavings you mention would make a powdery charcoal, that would do for mixing with the soil, and the lumps of Sycamore would do for drainage if not larger than walnuts, nor smaller than peas.

FANCY PELARGONIUM LEAVES TURNING YELLOW (*Anxious Inquirer*).—There is nothing wrong with the leaves. Their office is at an end, and they turn yellow and would fall if you did not pick them off. You should have cut the plants down after flowering to within three or four eyes of the old wood, or each shoot to within two or three eyes of its base, keeping the plants dry until they began growing, and then watering as required. You should have potted the plants when they had made shoots about an inch long, and you would now have had fresh green leaves. Cut them back now, and do not keep the soil more than moist. If green fly again appear fumigate with tobacco.

PENTSTEMON PROPAGATION (*Idem*).—Take the side shoots that come from near the root, slip them off, and pare the bottom smooth with a sharp knife: or cut them immediately below a joint. Trim off the leaves halfway up the cuttings, insert the latter that depth in sandy soil in a warm situation, and cover with a hand-glass. Keep the soil moist but not very wet, and shade from bright sun. Keep the light over the cuttings close for a month, then give air by tilting it. Cuttings may be put in now, but the end of August is, perhaps, the best time. They strike freely in spring and summer.

DIGGING BETWEEN STRAWBERRY AND RASPBERRY ROWS (*Idem*).—Nothing is more injurious than deep digging between plants. The ground should be cleaned and loosened a little, but not so deeply as to interfere with the roots, and the surface mulched with manure. It does not dry at this season as in summer, and the rains of autumn and winter will carry down to the roots its nutritive principles.

CATERPILLARS (*G. M. D.*).—They were the larvæ of some one of the Hawk moths; but without a full description of the colours of the body and horn, we cannot say which. We cannot publish what you write about the Pansies.

INSECTS—FRUIT (*T. E. G.*).—The insects attacking your Plums are hornets. The Pear is Beadnell's Seedling, but the Apple we do not recognise.

NAMES OF FRUITS (*I. C.*).—1, Winter Hawthornden; 2, Bedfordshire Foundling; 3, Wyken Pippin; 4, Brougham. (*Col. Rooke*).—We had to pay 6*d.* for your box. 3, Golden Reinette; 4, Margil; 8, Pearson's Plate; 13, Fearn's Pippin; 15, Beurré d'Aremberg. The others are all cyder and perry fruits, of which we have no means of knowing the names. (*W. Thompson*).—The Apple from Devonshire is Scarlet Pearmain. Though an ornamental and handsome Apple we do not know that it has ever

been grown extensively for market. (*Guernsey*).—The large green Apple is Alfriston, and that with a brown tinge on it is Warner's King.

NAMES OF PLANTS (*C. P.*).—Cerinthe minor. (*T. H. C. D.*).—1, Physalis edulis, the Cape Gooseberry; 2, Balsamita vulgaris—Costmary. (*A. B. C.*).—1, Bartsia odontites; 2, Achillea Ptarmica; 3, Juncus bufonius; 4, Carex vulpina; 5, Angelica sylvestris; 6, Sanicula europæa; 7, Oxyria reniformis. (*M. Parsons*).—Catalpa syringæfolia. (*Ignoramus*).—Blitum virgatum. (*L. M. H.*).—Your Fern is Lomaria spicant, var. cristata. It has been figured in "Lowe's Native Ferns," Vol. 2, where several other abnormal forms of the Hard Fern are described. (*An Inquirer*).—Some Solanum, most probably S. capsicastrum. We should be able to tell you with greater certainty if your specimen had been in bloom. The whole family is of a poisonous nature. (*Devon*).—1, Hypericum androsæmum; 5, Melissa officinalis variegata; 8, Celsia orientalis. The rest next week.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending September 28th.

POULTRY, BEE, AND PIGEON CHRONICLE.

A WORD FOR HOUDANS AT PUBLIC SHOWS.

My object in now soliciting space for a few lines is to endeavour to obtain a more prominent position for this valuable breed of poultry, in the hope that I may induce others who delight in Houdans, as I do, to urge with their greater ability and experience the committees of future shows to try and find a corner for them in a class by themselves.

To instance how little encouragement this useful breed as yet obtains at public exhibitions in this country, upon looking over the last half-dozen numbers of the Journal I find the descriptions of thirty-two different shows, out of which there are but three having classes for French poultry generally, only one giving a class for Houdans exclusively. An intending exhibitor must therefore enter them, if at all, in the "Any other variety" class; and if he considers for a moment the number of other breeds that can, according to the magnitude of the show, be brought against him, together with the attendant expense, increasing with the distance, it is enough to make him think twice before resolving to send his birds into such an unequal contest with such an uncertain issue.

It would appear upon first consideration, and many doubtless would say, that the other breeds competing against Houdans in the above class are just as much entitled to a separate one for themselves; and this would indeed be the case were I advocating more especially the cause of a purely "fancy" fowl. I hope I am right in saying, however, that the Houdan is not a purely fancy fowl, and therefore deserves to be selected individually. We cannot take up a paper or work upon poultry without seeing the useful qualities of Houdans extolled, and there is no breed so calculated for the profitable production of eggs and meat, either for the table of a private family or for the market from a farm; and the latter circumstance should be sufficient in itself for their encouragement in a country where poultry is so much neglected by the agriculturist.

Being pre-eminently the breed for a farmer, should not the introduction of Houdans over the country be attempted? for it is in this position poultry will be most profitable; and if this is the case, why, in an agricultural sense, should the Houdan not have a class in the same way that the famous Shorthorn so certainly does at every show? I should like to see the motley crew of barndoors partially give place, from homestead to homestead, to the black and white spangles of the Houdan, or at least have the Houdan element largely imported into them. Poultry produce would become more abundant, and the money that is now sent away in payment for the millions of eggs that are annually imported from France would be retained in the country. I must conclude with a hope that I may enlist your readers in the cause.—SCOTIA.

A CLEVER MOTHER HEN.—It is interesting to know and to notice the dangers and difficulties which eggs will go through during incubation without the brood being destroyed. On the 28th of July our old fowls were shut up for some cleaning bout, and when they were let out, a hen we have named Shortlegs bustled behind the house, as if some important matter depended on her immediate attention there, and so it did, for on following her we found her comfortably settling down on a stolen nest of thirteen eggs, all her own there is no doubt. As the 18th of August was thought too late for chickens, the eggs were taken away, and she was left to go to roost in the henhouse; this happened towards evening; the weather was quite dry, but very warm. In the morning cool reflection came; it was considered that those thirteen eggs, if boiled for breakfast, might disclose something not appetising to the fastidious, and poor Shortlegs was puffing and fretting for them, so they were given up to her in the nest she had made, after being kept away about fifteen hours. They were given to her without an idea that they had been sat on previous to her so eagerly taking possession the evening before. That day fortnight she neglected to come off to feed, and so was looked after again, when a lot of little heads were popping out around her. She had hatched ten chicks, two were dead in the shell. I believe we should have had twelve from the thirteen eggs if we had known of their hatching, and bestowed a little necessary attention in removing the eggshells.—E. WATTS.

POULTRY DURING AN ECLIPSE OF THE SUN.

I WELL remember the effect of a total eclipse of the sun, I think in 1836, upon the fowls in my poultry yard. The old Dorking cock repeatedly turned his head on one side to look at the sky as it became darker, as if he thought there was something wrong; but at length he became convinced that it must be evening, and he and his wives betook themselves to the roost-house. But, even then, before perching, he put his head out, and took a final look upwards as if to be certain there was really no mistake. Before they were well settled, the eclipse gradually terminating, the fowls came down again from their perches, and when the old cock emerged from the house, and before venturing to crow, he looked up at the sky, and there was evidently an impression that if there was not a mistake somewhere, the night had passed marvellously quickly. This was all recalled to my remembrance by reading the following in an American newspaper:—Dr. Peters, the eminent astronomer connected with Hamilton College, went west to observe the late eclipse of the sun. He requested an old negro living near his observatory to watch his big flock of hens, for at 4-45 they would go to roost. After the eclipse was over, the negro came, evidently much excited. "How was it?" said the doctor. "Beats ebbery tink," said the negro. "When de darkness come, ebry chick'n run for de hole in de barn. De fust ones got in, and de next ones run ober one anudder, and de last ones dey just squat right down in de grass. How long you know dis ting was a-coming?" "Oh, I reckon we knew it more than a year," said the doctor. "Beats de debbil! Here you away in New York knowd a year ago what my chick'ns was gwine to do dis bery afternoon, an' you nebber see de chick'ns afore nudder."—G.

NORTH BRITISH COLUMBARIAN SOCIETY.—Our Scotch friends are again to the front in Pigeon matters, as a copy of the schedule of their eleventh annual Show, to be held in Glasgow

on the 16th and 17th of December, lies before me. They have, I see, changed their quarters to the Drill Hall—a happy augury that they may have many volunteers to the Pigeon fancy. The President, Vice-President, Treasurer, and Honorary Secretary are our old friends—Messrs. Montgomery, Muir, Wallace, and Ruthven. The schedule is divided into two portions:—classes for members' competition only, for birds bred in 1869, which must be bred by the exhibitor; and class prizes given by the Society, open to all competitors. In the former the prizes consist of twelve silver medals for Pouters, value one guinea each, two for Carriers of two guineas' value, one of the same value for Barbs, and the same for Short-faced Tumblers. With respect to the class prizes given by the Society, and open to all competitors, there are fourteen prizes of 20*s.* each for Pouters, and the like number of 10*s.* and 5*s.* prizes, and a silver medal, value £2 2*s.*, as a special prize for the cock Pouter, best in form and carriage, and a similar silver medal for the best hen Pouter, offered by Capt. Heaton. Then five prizes for Carriers and a medal; two for Short-faced Tumblers and a medal; two for Barbs and a medal; Fantails one prize—*i.e.*, one first, one second, and one third; this is the case throughout. Jacobins, two and medal; Trumpeters, three and medal; Turbits, one and medal; English Owls the same; Foreign Owls also the same; Nuns a prize; so also Beards, Balds, or Tumblers. A prize is also given (20*s.*, 10*s.*, and 5*s.*) for Antwerps. Most properly "it is requested by the Society that exhibitors attach to the entries for this class certificates of performances as flyers, which will be published in catalogue." The schedule finishes with a prize for Dragoons, and one for Fancy Pigeons, not otherwise classed; and a prize of a guinea to the pair of birds most beautiful in plumage. I heartily wish the Committee a good show, good weather, and plenty of visitors.—Wiltshire Rector.

PENCILLINGS FROM AYLESBURY.

You know, Messrs. Editors, what a rambler I am; how at one time I am in Surrey, at another in Sussex; how on one occasion I found myself at Clifton, at another at Leighton. You will, therefore, I trust, forgive me if I send you the results of a ramble which I resolved upon for the purpose of viewing the poultry show held at Aylesbury on the 22nd inst.

The place is, indeed, quite a type of a country town, having a good open square in the centre, a noble market and Corn Exchange, to say nothing of the church, which has been restored and beautified in no ordinary manner, in a great measure, I am told, through the efforts of that veteran fancier, Mr. John Fowler. Accompanied by a friend, who had come all the way from Surrey to see the Show, and as he hoped, to carry off a silver cup, I wended my way to the Market House, whither the chorus of the chanticleers summoned us in terms which could not be mistaken. At the door were eager exhibitors, anxiously awaiting the signal for admission; a few, however, seemed to be already aware of the results in certain classes, though how this was managed your deponent knoweth not. Some members of the Committee can probably explain the difficulty. About one o'clock we learnt that the Judge's labours were almost over, and that we might enter. Considering that thirteen or fourteen silver cups were offered for competition, we naturally expected a first-rate show; but this it can scarcely be called. Some of the classes were unquestionably good. The *Dorkings*, in particular, were pronounced to be excellent, and seventeen entries from all parts of England proved that there was a determined struggle for the possession of the two silver cups. The award of the Judge with respect to these no one appeared inclined to question; but the third-prize pen certainly seemed inferior to some others, the comb of the cock being such as would have frightened Mr. Hewitt. Close by was a magnificent cockerel with a pullet equally good, which seemed worthy of some notice; broken and twisted toes, and possibly crooked breasts, may have led the Judge to pass them by. An exhibitor in this class seems to have made a mistake with regard to his birds. They reminded me (hearing as I did but one opinion from the most experienced fanciers) of the old saying, that "men are but children of a larger growth," which here appeared to run, "cocks are but cockerels of a larger growth." A similar mistake, it was confidently asserted, had been made in the *Spanish* class, round which at one time words ran high, and voices were far too loud to be musical. The *Ducks*, it need scarcely be said, were very good; Mrs. Seamons and Mr. Fowler, as usual, holding their own. The *Turkeys*, though few in number, were good. Here, again, it was confidently declared that an old bird was entered in a class in which chickens only could claim a prize, and the old scales on the hocks offered ocular proof of what no one could doubt. The *French* fowls were fairly represented; and everyone would admit that Mr. Leno deserved the first and second prizes he won with his *Bantams*. The *Geese* were excellent, but in one pen two ganders led one to suppose that the owner was scarcely aware of the conditions of the Show. The *Hamburghs* and *Polands* were far from numerous, and the Light *Brahmas* did not obtain even a commendation, their darker brethren being decidedly good.

As the question of compound foods has been before your readers, I may mention that I was assured by the owners of two of the finest pens in the exhibition, one of them the winner of a silver cup, that they had used no compound food whatever in producing what really were first-rate results.

My reflections on returning from my ramble, I found, were of a very mixed character. Delighted as I had been to see such beautiful specimens of my feathered friends, I could not but regret that so many charges of dishonesty should be brought, and I fear with too much truth, against some who ought to care to win only with honour. To enter old birds as chickens, or ganders as Geese, is really an attempt to obtain for yourself what belongs to another, and no man with a spark of good feeling would condescend to such tricky shamelessness. Honesty, however, is after all the best policy—it is the good birds, and the honest exhibitors, that in the long run win; and even if a judge is now and then deceived, the deceit does not last an hour, while the exhibitor earns for himself the contempt of all whose good opinion is worth having. I wished, too, that certain exhibitors would take with them a larger supply of good temper. To hear the language of some of them, attacking first one and then another, never content except they had appropriated everything to themselves, one would suppose that no one else possessed anything worth having. Happily this is not the case with the great majority of poultry fanciers; for myself I may say that the fancy has led me to make the acquaintance of many whom I cannot but esteem, while it has solaced hours of sadness, and relieved the tediousness of a wearying occupation.—E. M. B. A.

The following is the list of awards:—

Dorkings (Any variety).—1, J. Longland, Grendon. 2, Rev. E. Bartrum, Great Berkhampstead. 3, J. Smith, Shillinglee Park, Sussex *hc* and *c*, L. Patton, Hillmore, Bishops Hull.

Brahmas (Any variety).—1, Cup, and 2, H. B. Morrell, Cae Mawr, Clyro. 3, H. Brown, Putney Heath. *hc*, Mrs. Burrell, Ipswich; C. Layland, Morris Brook, Warrington; J. K. Fowler.

Spanish.—1, J. Laming, Cowhorn, Spalding. 2, W. R. Bull, Newport Pagnell. 3 and *hc*, F. James, Peckham Rye.

Cochins (Buff).—1, C. Sidgwick, Ryddlesden Hall, Keighley. 2, J. H. Dawes, Moseley Hall, Birmingham. 3, F. W. Rust, Hastings. *hc*, Mrs. Burrell.

Cochins (Partridge).—1, C. Sidgwick. 2 and 3, J. K. Fowler, Aylesbury.

Game (Black-breasted and other Reds).—1 and Cup, J. R. Fletcher, Stoneclough, Manchester. 2 and 3, S. Matthew, Stowmarket. *hc*, T. Dyson, Halifax.

Game (Any other colour).—1, T. Dyson.

French Fowls (Crève-Cœurs).—1 and Cup, J. J. Malden, Biggleawade. 2, Miss E. Williams, Heollys, Berriew. 3, Mrs. M. Seamons, Hartwell, Aylesbury.

French Fowls (Any other variety).—1 and 2, O. Quihell, Newark. 3, C. Layland.

Hamburghs Gold or Silver-pencilled).—1 and Extra Prize, R. R. Parker, Ipswich. 2, J. Laming. 3,—Barford, Aylesbury. *hc*, S. Burn, Whitby.

Hamburghs (Gold or Silver-spangled).—1, J. Laming. 2,—Barford.

Game Bantams.—1, H. C. Rogers, Newport Pagnell. 2, W. Adams, Ipswich. 3, F. Pittis, Newport, Isle of Wight.

Bantams (Any other variety).—1 and 2, M. Leno, Dunstable. 3, J. Laming.

Any other Variety not Before Mentioned.—1, J. Laming. 2, J. K. Fowler. 3, C. Sidgwick.

Ducks (Aylesbury).—1, Mrs. M. Seamons, Hartwell, Aylesbury. 2 and 3, J. K. Fowler, *hc*, H. Jones, Dinton, near Aylesbury. *c*, Mrs. Burrell. (Maiden Class).—1, W. Weston, Aylesbury. 2, J. Funge, Long Marston. 3, T. Kingsley, Borascroft. *hc*, J. Funge.

Ducks (Rouen).—1, J. K. Fowler. 2, S. H. Stott, Rochdale. 3, J. L. Lowndes, Aylesbury.

Ducks (Any other variety).—1, S. Burn. 2, C. N. Baker, Chelsea. 3, Lieut.-Col. H. B. Lane. *hc*, C. N. Baker; M. Leno.

Geese (Any variety).—1, J. K. Fowler. 2, Mrs. M. Seamons. 3, S. H. Stott. *hc*, J. K. Fowler; Mrs. M. Seamons.

Turkeys (Any variety).—1 and 2, L. Patton. 3, S. H. Stott.

Guinea Fowls.—1, Miss T. A. Cresswell, Hounslow. 2, J. Treadwell, Upper Winchendon.

Pheasants (Any variety).—1, M. Leno. 2, 3, and *hc*, J. K. Fowler.

Selling Class.—1, J. K. Shrimpton, Easington. 2, H. Jones. 3, H. Brown, Putney.

Pigeons.—*Carriers* (Any variety).—1, P. H. Jones. *Pouters* (Any variety).—1 and 2, P. H. Jones. *Fantails* (Any variety).—1, P. H. Jones. 2, F. Graham, Birkenhead. *hc*, J. F. Loversidge, Newark. *Any other*

Variety.—1 and 2, P. H. Jones. *hc*, J. K. Fowler; H. Gurney, Aylesbury; P. H. Jones; F. Graham.

JUDGE.—Mr. G. S. Sainsbury, Devizes.

WOODSTOCK AGRICULTURAL ASSOCIATION'S POULTRY SHOW.

THE twelfth annual Show of this Society was held in Blenheim Park, on September 21st., and was one of the most successful meetings ever held there. The following are the awards:—

DORKINGS.—1, J. Hutt, Thrupp, Kidlington. 2, H. L. Gaskell, Kiddington Park. 3, Duchess of Marlborough, Blenheim Palace. *Chickens.*—1 and 3, Duchess of Marlborough. 2, J. Hutt.

BRAHMAS.—1, Duchess of Marlborough. *Chickens.*—1, — Keene.

HAMBURGHS.—*Spangled.*—1 and 2, — Godden, Woodstock. *Chickens.*—1, — Evans, Marston, near Oxford. 2, — Godden. *Pencilled.*—1, — Aries, Kiddington, near Oxford. 2, — Warmington, Woodstock. *Chickens.* 1 and 2, — Brimfield, Exeter College, Oxford.

GAME.—1, J. Hutt. 2, — Warmington. *Chickens.*—1, J. Hutt. 2, Withheld.

GEESE.—1, Duchess of Marlborough. *Goslings.*—1, Duchess of Marlborough.

DUCKS (Aylesbury).—1, Duchess of Marlborough. 2, A. Bowyer, Steeple Ashton. *Ducklings.*—1, — Amies, Coombe. 2, H. L. Gaskell.

DUCKS (Rouen).—1 and 2, — Woodford, Kidlington. *Ducklings.*—1, — Woodford. 2, H. L. Gaskell.

DUCKS (Any variety)—1 and 2. — Lester, Glympton, Woodstock. *Ducklings.*—1, — Lester. 2, Wilsdon, Woodstock.

TURKEYS (Black).—1, Duchess of Marlborough. *Poults.*—1, Duchess of Marlborough. 2, H. L. Gaskell.

TURKEYS (Grey).—1, Duchess of Marlborough. *Poults.*—1, Duchess of Marlborough. 2, — Daves, Kensington, Woodstock.

SPECIAL PRIZES (Given by the Duchess of Marlborough).—1, J. Hutt. 2, W. Pratt, Woodstock.

CHAMPION PRIZE (Given by the President, James Mason, Esq., Eynsham Hall).—1, Duchess of Marlborough. *Chickens.*—1, — Keene.

JUDGE.—Mr. G. S. Sainsbury, Devizes.

BURTON-ON-TRENT POULTRY SHOW.

FEW shows of poultry have been so well supported as that which took place at Burton-on-Trent on the 23rd inst. Held in a locality easily accessible to a dense population, and having the assistance of many local poultry-keepers, success was almost a certainty, and but for a few flitting showers, all went on as pleasantly as possible. Some birds among the *Game*, though moulting, were especially noticeable, and the show of *Dorkings* was unusually good. *Cochins* might have been shown in higher condition, but the *Brahmas*, both Light and Dark-feathered, were excellent. *Hamburghs* were so well represented, that it was worth making a long journey to see them. The single cock class was a signal failure. The *Turkeys*, the *Geese*, and the classes for domesticated *Ducks*, were really admirable; and in the extra class were some very creditable specimens of Sebright *Bantams*, which obtained extra prizes. The tent was exceedingly commodious, and the general arrangements first-rate.

YOUNG BIRDS.

GAME (Black-breasted and other Reds).—1, Duke of Sutherland, Trentham Hall. 2, R. Ashley, Nantwich. *hc*, W. H. L. Clare, Twycross, Atherstone.

GAME (Any other variety).—1, Duke of Sutherland. 2, R. Ashley. *hc*, Master J. Fletcher, Stonecclough, Manchester (Piles).

SPANISH.—1, J. Walker, Wolverhampton. 2, T. & E. Comber, Myddleton Hall, Warrington.

DORKINGS (Coloured, except Silver-Greys).—1, Mrs. F. S. Arkwright, Etwall Hall, Derby. 2, L. Patton, Hillmore, Bishop's Hull, Taunton. *hc*, Countess of Chesterfield, Bretby Hall, Burton-on-Trent; S. H. Stott, Rochdale. *c*, Mrs. F. S. Arkwright.

DORKINGS (Silver-Grey or White).—1, Countess of Chesterfield. 2, Lady Bagot, Blithfield Hall, Rugeley. *c*, Miss E. Williams, Henllys, Berriew.

COCHIN-CHINA (Cinnamon or Buff).—1, Mrs. Allsopp, Hindlip Hall, Worcester. 2, C. Sidgwick, Ryddlesden Hall, Keighley. *hc*, J. H. Dawes, Birmingham.

COCHIN-CHINA (Brown, Partridge-feathered, or other varieties).—1, Mrs. A. Williamson, Queniborough Hall, Leicester. 2, C. Sidgwick. *hc*, H. Lingwood, Martlesham, Woodbridge. *c*, A. O. Worthington, Newton Park, Burton-on-Trent.

BRAHMA POOTRA (Dark).—1 and 2, Rev. E. Alder, Etwall Vicarage, Derby. *hc*, Rev. E. Alder; H. Lingwood; H. B. Morrell, Cae Mawr, Clyro, Hay. *c*, Mrs. A. Williams, Rearsby, Leicester.

BRAHMA POOTRA (Light).—1, Mrs. A. Williamson. 2, H. Lacey, Hebden Bridge. *hc*, H. M. Maynard, Holmewood, Ryde.

HAMBURGHS.—*Golden-pencilled.*—1, W. K. Tickner, Ipswich. 2, Duke of Sutherland. *c*, H. Pickles, jun., Earby; Duke of Sutherland. *Silver-pencilled.*—1 and *hc*, Duke of Sutherland. 2, H. Pickles, jun. *c*, Mrs Allsopp. *Golden-pencilled.*—, E. Brierley, Heywood, Manchester. 2, H. Pickles, jun. *hc* and *c*, Duke of Sutherland. *Silver-spangled.*—1 and *hc*, Duke of Sutherland. 2, H. Pickles, jun.

SINGLE COCKERELS.—*Game.*—1, W. H. L. Clare. *Dorking.*—1, Mrs. F. S. Arkwright. *Cochin-China.*—1, A. O. Worthington.

TURKEYS (Any variety).—1, Mrs. A. Guy, Eaton, Grantham. *hc*, F. E. Richardson, Bramshall, Uttoxeter; E. Leech, Rochdale; S. H. Stott, Rochdale.

GOSLINGS.—1, S. H. Stott. 2, Rev. G. Hustler, Stillingfleet Vicarage, York. *hc*, J. Faulkner; E. Leech; S. H. Stott. *c*, G. J. Mitchell, Burton-on-Trent.

DUCKLINGS (White Aylesbury).—1, C. Havers, Ingatestone, Essex. 2, E. Leech. *hc*, S. H. Stott. *Rouen.*—1 and 2, W. H. Robson. *hc*, A. O. Worthington; W. Gamon, Hoole Cottage, Chester; S. H. Stott. *c*, E. Leech. *Any other Distinct Variety.*—1 and 2, A. O. Worthington.

EXTRA CLASS.—1 and 2, Viscount Anson, Ranton Abbey, Eccleshall (Silver-laced Sebright and Golden-laced Sebright). *hc*, Viscount Anson (Golden-laced Sebright Bantams); J. Neville, Haselour Hall, Tamworth (Silky).

The Judges were the Rev. Thomas O'Grady, of Ashbourne, and Edward Hewitt, Esq., of Birmingham.

HIPPERHOLME POULTRY SHOW.

THIS Show was held September 18th. The number of entries was not large, but any deficiency in this respect was fully compensated for by the quality of the birds. There was a large entry of *Game*, and the competition was very close, many first-class birds only receiving commendations. The entry of *Cochins* and *Spanish* was small, but the winning pens were good. The *Hamburgh* class was superior; the first-prize pen of Silver-spangled was excellent. Of *Game Bantams* there was a large and fair class. The "Any variety" class was composed of Black Hamburghs and Polands, all good birds; the first prize being awarded to an extra pen of Black Hamburgh chickens. Rouen *Ducks* are increasing in numbers and quality, and ought to have prizes awarded them, independently of the "Any variety" class. It would be much better when shows are held so late as September, if only chickens were allowed to compete, as adult fowls are generally in the moult, and not fit for exhibition.

GAME COCK (Any colour).—1, H. Jowett, Idle. 2, R. Hemingway, Shelf. 3, Green & Sutcliffe, Queensbury. *hc*, T. Dyson, Halifax.

GAME (Black-breasted or other Reds).—1, T. Dyson. 2, H. Jowett.

GAME (Any other variety).—1, T. Dyson. 2, J. Sunderland, Coley Hall, Hipperholme. 3, H. Jowett. *hc*, T. Denton, Southowram. *Hen or Pullet.*—1, R. Hemingway. 2, A. S. Riley, Kirkburton. *hc*, M. B. Wyvill, Shelf; C. Ashworth, Halifax.

COCHIN-CHINA (Any variety).—1 and 2, C. Sidgwick, Ryddlesden Hall, Keighley.

SPANISH.—1 and 2, J. Thresh, Bradford.

HAMBURGHS.—*Golden-spangled.*—1, H. Pickles, jun., Earby, Skipton. 2, W. Driver, Morton Banks, Keighley. *Golden-pencilled.*—1, W. Clayton, Morton Banks, Keighley. 2, H. Pickles, jun. *hc*, S. Smith, Northowram. *Silver-spangled.*—1, Ashton & Booth, Mottram. 2, W. Bairstow, Bingley. *hc*, W. Bairstow; H. Pickles, jun.; T. Garnett, Idle. *Silver-pencilled.*—1, T. Garnett. 2, H. Pickles, jun.

GAME BANTAMS (Any colour).—1, F. Steel, Stamp Cross, near Halifax. 2, M. B. Riley, Woodside, Hipperholme. *hc*, S. Speak, Range Bank, Halifax; F. Steel.

BANTAMS (Any other variety).—1, J. Walker, Halifax. 2, M. B. Riley. *hc*, M. B. Riley; J. Longbottom, Halifax.

ANY OTHER DISTINCT VARIETY. 1, C. Sidgwick. 2, H. Pickles, jun. *hc*, J. S. Senior, Dewsbury; H. W. Illingworth, Idle.

DUCKS (Aylesbury).—1, M. B. Riley

DUCKS (Any other variety).—1, J. S. Senior. Extra 1 for local prize, M. B. Riley. 2, C. Sidgwick. Extra 2, S. & R. Ashton, Mottram.

PIGEONS.—*Dragoons.*—1, F. Steel. 2, J. S. Senior. *Owls.*—1, F. Steel. 2, T. Eggleston Halifax. *Turbits.*—1, T. Eggleston. 2, T. Denton, Southowram. *Fantails.*—1, T. Eggleston. 2, J. E. Robson. *Common.*—1, F. Steel. 2, W. Mitchell, Hipperholme. *Any other Variety.*—1, J. S. Senior. 2, T. Eggleston.

JUDGES.—Mr. Dodds, Wakefield; Mr. Joseph Walker, Haya-Park, Knaresborough.

MARCH POULTRY SHOW.

THE Show at March was admirably conducted, and for the first time it was held on two consecutive days—viz., September 22nd and 23rd. Every accommodation was secured for the birds, whether fowls or Pigeons, and Mr. Bellott's well-known exhibition pens showed all to the fullest advantage, a large tent affording ample protection from the weather. Grey *Dorkings* were a fair class, but the class for any other variety of Dorkings was as bad as it well could be; the Grey Dorking chickens were excellent. The *Game* for the most part were not in full plumage. Many pens of *Hamburghs* were shown that would be most creditable to any show, and there were also some decidedly good *Brahmas*. *Turkeys* and *Geese* were good, but the chief feature of the show-tent was the collection of *Pigeons*. No doubt the success of this division of the Show this year will only be a prelude to its extension on future occasions. The attendance was especially good.

DORKINGS (Coloured).—1, R. Wood, Clapton, near Thrapstone. 2, F. Parlett, Great Baddow.

DORKINGS.—*Chickens.*—1, J. Roper, Barham, Ipswich. 2, R. Wood. *hc*, J. B. Harvey, Tuddenham, Mildenhall (Blue-speckled); Rev. F. Tearle, Gazeley Vicarage, Newmarket; F. Parlett; G. S. Hall, Ely.

GAME (Black-breasted or other Red).—1 and 2, S. Matthew. *hc*, J. T. Ashley, Litcham.

GAME (Any other variety).—1, S. Matthew (Duckwings). 2, S. Deacon, jun., Oundle.

COCHIN-CHINA (Buff).—1, J. H. Dawes, Birmingham. 2, W. C. Little, Stag's Holt, March.

COCHIN-CHINA (Any other variety).—1, H. Lingwood, Woodbridge, (Partridge). 2, Miss Hales, Canterbury (White). *c*, R. W. Smith, Grandford, March (Partridge).

GAME BANTAMS (Any variety).—1, A. Storrar, Peterborough (Black-breasted Red). 2, W. Adams, Ipswich (Black-breasted Red). *c*, F. Richardson, Chatteris.

BANTAMS (Sebrights, Golden, or Silver).—1, Miss A. Hodson, North Petherton, near Bridgewater. 2, T. C. Harrison, Hull. *c*, Rev. F. Tearle.

BANTAMS (Any other variety).—1, G. S. Hall, Ely (White feather-legged). 2, Rev. F. Tearle. Extra 2, S. & R. Ashton, Mottram. *c*, A. Storrar (Black).

HAMBURGHS (Golden or Silver-spangled).—1 and Cup, H. Pickles, jun. Skipton. 2, S. & R. Ashton.

HAMBURGHS (Golden or Silver-pencilled).—1, W. K. Tickner, Ipswich. 2, H. Pickles, jun.

SPANISH.—1, T. C. & E. Newbitt, Epworth. 2, G. S. Hall, Ely.

BRAHMA POOTRA (Dark).—1, J. T. Ashley. 2, H. Dowsett, Pleshey, Chelmsford.

BRAHMA POOTRA (Light).—1, J. Pares, Postford, Guildford. 2, H. Dowsett.

ANY OTHER VARIETY.—1, H. Pickles, jun. (Polands). 2, T. Spurr, King's Lynn (Japanese). *c*, A. S. Rae, Ely (Silver-spangled Polish).

ANY BREED EXCEPT DORKINGS.—*Chickens.*—1, H. Dowsett. 2, W. Dring, Faversham (Houdans). *hc*, Miss Hales, Canterbury (Light Brahmas); W. K. Patrick, Lynn (Polands); Mrs. E. Williams, Henllys (Crêve Cœurs).

SELLING CLASS.—1, Dr. D. C. Campbell, Brentwood. 2, B. Branford, March (Silver-pencilled Hamburghs).

TURKEYS (Any variety).—1, T Morton, Offord D'Arcy (Cambridge). 2, G. S. Hall. *hc*, J. B. Hides, Wisbech Fen (Cambridge).

DUCKS (Rouen).—1, L. Patton, Hillmore, Taunton. 2, G. S. Hall.

DUCKS (Aylesbury).—1, S. Deacon, jun., Oundle. 2, C. Havers, Ingatestone.

DUCKS (Any other variety).—1, S. & R. Ashton. 2, T. C. Harrison.

GEESE (Any variety).—1, J. T. Ashlev. 2, A. Grounds, March. *Goslings.*—1, J. T. Ashley. 2, T. Morton. *hc*, H. Mitchell, Warboys.

PIGEONS.

CARRIERS.—1, F. W. Metcalfe, Cambridge. 2, J. Addison, Cambridge. *hc*, R. Hall, Cambridge; H. Yardley, Birmingham. *c*, E. Walker.

TUMBLERS.—1, J. H. Irving, Lingfield, East Grinstead. 2, J. Fielding jun., Rochdale.

OWLS.—1, J. Fielding, jun. 2, G. S. Hall (White). *hc*, J. Fielding, jun. J. H. Irving.

POUTERS. — 1, R. Ruston, jun., Chatteris. 2, E. Walker, Leicester. *hc*, G. S. Hall; H. Yardley.

BARBS.—1 and 2, J. H. Irving. *hc*, J. Fielding, jun.; H. Yardley.

FANTAILS.—1, H. Yardley. 2, T. C. & E. Newbitt. *hc*, G. S. Hall.

JACOBINS.—1, T. C. & E. Newbitt. 2, H. Yardley. *hc*, G. Johnson, Kettering.

TURBITS.—1, H. Yardley. 2, J. Fielding, jun. *hc*, T. C. & E. Newbitt.

ANY OTHER VARIETY.—1, H. Yardley. 2, T. C. Marshall (Magpies). *hc*, T. C. Marshall (Magpies); J. T. Ashley (Runts); H. Yardley.

SELLING CLASS.—1, H. Yardley. 2, E. Walker (Pouters). *c*, Lady Pigot, Branches Park, Newmarket (Nuns).

EXTRA.—*c*, C. B. Bates (Doves).

Edward Hewitt, Esq., of Sparkbrook, near Birmingham, was the Judge.

LANCASTER POULTRY SHOW.

THE tenth annual Exhibition of the Lancaster Agricultural Association was held at Lancaster on the 21st inst. The following are the awards made for poultry, the Show of which was but small :—

GAME (Any colour).—1, T. Mason, Lancaster. 2, J. Hodgson, Burton. *c*, J. Hodgson; T. Mason. *Cock.*—1, J. Hodgson.

HAMBURGHS.—*Golden-pencilled.*—1 and 2, B. Bee. *Silver-pencilled.*—1, J. Robinson. 2, B. Bee. *Golden-spangled.*—1 and 2, J. Robinson. *Silver-spangled.*—1 and 2, J. Robinson.

DORKINGS.—1, R. Smalley. 2, W. H. Butcher. *c*, R. Smalley; J. Robinson.

COCHIN-CHINA (Any colour).—1 and *c*, J. Robinson. 2, J. Parkinson.

SPANISH (Black) —1 and *c*, G. Standen.

GAME BANTAMS.—1, W. H. Butcher. 2, J. Parkinson. *c*, J. Robinson.

TURKEYS.—1, J. Cock. 2, R. Richmond. *c*, R. Stackhouse.

DUCKS.—*Aylesbury.*—1 J. Robinson. 2, B. Bee. *c*, J. Robinson; R. Smalley. *Rouen.*—1, J. Parkinson. 2, J. Walker. *c*, J. Robinson.

GEESE.—1, W. H. Butcher. 2, R. Sandham. *c*, R. Stackhouse.

JUDGES.—Mr. R. Teebay, and Mr. Tait.

LOP-EARED RABBITS:

THEIR POINTS AND THEIR JUDGES.

LOUD and many have been the complaints of late concerning the judging of Rabbits at the poultry shows, and if we are to believe in the old axiom, that where there is much smoke there is some fire not far off, we must conclude that these complaints are not unfounded. Indeed, what can be more natural than that men whose hearts and hobbies are simply in the feathered tribe, should feel comparative indifference, and perhaps even contempt, for a fancy in which their sympathies have never been enlisted? and this being the case, can it be wondered at that the Rabbit section should be slurred over, sometimes from sheer impatience and distaste for the task, or from absolute ignorance of the points which constitute the excellence of the specimens? I feel confident that it would pay any committee to offer £1 and 10*s.* for first and second prizes, if they would but let it be known distinctly that a special judge would be appointed for Rabbits, for there is nothing but uncertainty at present; and how can it be expected that an exhibitor will send his Rabbits fifty or a hundred miles or more, spending 5*s.* in entrance fee and carriage, when the first prize is only 10*s.*, and without having (for this is the great consideration), any sort of guarantee that they will be judged by men who understand them?

Now, the points of a Lop-eared Rabbit are well defined and universally recognised by the fancy; but as it appears that they are sometimes lost sight of, it may not be ill-timed to put them down in a concise form, and then say a few words on each point. First, Length of Ear; second, Width of Ear; third, the Marking; fourth, Position of Ear; fifth, the Make and Carriage; sixth, the Eye; seventh, the Weight. As to Colour, it cannot be called a point, one colour being the favourite at one time, and then, perhaps, some other taking its place; for instance, blue and white was once a favourite colour, but now there are only two shows in England where the classes are arranged with regard to colour, and where blue and white is specially mentioned. Perhaps, however, we should be right in saying that at present the colours stand in the following order: —black and white, yellow and white, tortoiseshell, blue and white, grey and white, all self colours being equal, or, if not, grey coming last.

Now, as to the first point—*Length of Ear.*—However the idea first originated, it is certain that during this century the paramount aim among Lop-ear fanciers has been to breed length, and it is astonishing what they have done of late years. A very few years ago 20 inches were thought a marvel, and there are fanciers now connected with the Kent and Surrey Club who remember the first Rabbit that reached the then extraordinary length of 19 inches. It was bred by the late Mr. Baxter, of Whitechapel, and so keen was the bidding for it, that he said he would not take less than a guinea an inch, and it was bought at that figure by the late Dr. Ducheyne. The word "breeding," so far as the lop ear is concerned, means, I conceive, nothing more nor less than Nature turned literally upside down. I believe there is not a wild lop-eared Rabbit in any country, but that they have all come from a prick-eared stock, and been obtained by art, and on the principle of selection. No breeder at all events, will deny that it is impossible to get length of ear without warmth, which goes some way towards proving my position. Take a few ordinary wild English Rabbits, and you will find that their successors in a few generations will, from the enervating influence of warmth and confinement, be ear-lopped (their ears reminding you of the oars of a boat), and after a while they will be perfectly lopped and hang dead down, the confinement, with artificial feeding, giving them a size which you do not see in the wild Rabbit, aided, of course, by a selection of the largest and best in other respects for breeding purposes. But Nature, if you turn her out with a pitchfork, will come back again if you do not watch her. Turn your fine lop-ears into a paddock, and they will soon come to the oar-lop, and you will eventually find your old-fashioned little friends, the prick-ears, back again. I have not seen this theory discussed in any book, but I have certainly heard nothing that at all shakes my confidence in its correctness, though I am open to conviction if any of your more intelligent contributors can enlighten me. However, would guard myself against being understood to say that all prick-eared Rabbits might in time produce lop-ears. I should like to live till this would be the case with Himalayans, which certainly come from hot countries.

To return, after a short digression, to the first point. In measuring for length, it is well to have some wash-leather glued to one end (which we will call the beginning) of the rule, as the finger and thumb of the left hand have then a firmer hold of the tip of the ear without hurting the patient, and if the other end is steadied by a friend, the pulling of the right ear with the finger and thumb is simple; all the indiarubber lies in the 3 last inches.

2. *Width of Ear.*—Lay the rule straight across the widest part of the ear with the assistance of a friend, and pull it what little it is capable of. A well-shaped ear will be wide and round at the end, and this is always considered a great recommendation for breeding purposes.

3. *Marking.*—There should be a white dash on the forehead, a little white on each side of the nose, coming up from the jaw and breast, a very short chain of white spots on each shoulder, and then an unbroken colour on the back right down to the tail, forming what is commonly called the saddle, the belly and legs being perfectly white like the breast. As to an unbroken colour, there must be an exception with regard to Tortoiseshells, where a variegated colour is a beauty; but there must only be white where I have named. There is an exceedingly beautiful stuffed specimen of a variegated Tortoiseshell in the British Museum, presented by no less notorious a

personage than Mr. Calcraft, who, it may not be generally known, was twenty years ago a highly successful and humane breeder of Lop-ears.

4. *Position of Ear.*—The round or convex side should be outwards, and it cannot hang too close to the face, or too much forward.

5. *Make and Carriage.*—A Rabbit should be broad and low in the shoulder, and high behind, always provided it is not low from weak and crooked legs; this gives shapeliness and elegance to its movements when combined with length. The head of a doe should be long and fine, and some even prefer a buck with this characteristic, but some think that, like a bull-dog's, the uglier it is the better.

6. *The Eye.*—This should be large, bright, and prominent, like that of the wild Rabbit. In judging, I should not attach so much importance to the eye in a grey or grey and white as in other colours, as it is always larger, probably owing to their retaining more of the original type, as their colour betokens.

7. *Weight.*—Here the scales are the best judges.

I would now invite some of your more experienced readers, such as Mr. Rayson, "Himalayan," and others, to say something on the "variety" classes, as they would, doubtless, be able to do the subject more justice than I could.—B. Hudson, *Hull.*

COLOURING AND STAINING BIRDS FOR EXHIBITION.

In the capital report of the bird show at Whitby, in "our Journal" of September 23rd, I was sorry to read of another instance of Canary-staining, and I entirely agree with Mr. Blakston, who says, "I wish all societies would banish such offenders, and so stamp out the disease." Acting with determination in refusing the entries of those whose attempted impositions have been detected, is, I consider, an effectual plan to adopt. Good and true exhibitors will then know there is some protection for them. One thing I should like to see carried into effect, that of posting up in every bird-show room in England the names of those who may have committed themselves at any exhibition, and this exposure to be continued for a certain period. There is a law to punish an offender who tries to impose a counterfeit coin upon another person, and I really look upon an individual who defaces Nature's works as the worse of the two. If secretaries of shows, and exhibitors also, have no Act of Parliament to protect them, I think it high time that an association—one general association of all the well-meaning breeders and exhibitors throughout the country—were formed, and then some effectual method could be framed for checking the often-practised artificial-colouring system.

At two of the recent summer shows—one at York, the other at Leeds—I detected three instances of stained Canaries. That at the former place was a most glaring instance, and I never felt more disgusted. It was that of a Clear Yellow Norwich, shown by a Mr. Bailey, with whom I afterwards had some conversation on the York show-ground. He sought an interview, and doubted whether his bird was coloured. I produced a white handkerchief with some of the colouring matter upon it, when he said, "I purchased the bird of a Northampton man, and shall send it back, and I wish to ask you, if he do not return the amount paid for it, will you give evidence should I take proceedings in the County Court for its recovery?" To this I agreed. Now, as the show took place about midsummer, and as I met Mr. Bailey in the Royal Park, Leeds, a month back, and he not having even mentioned the circumstance, I, in justice to the Northampton school, must say that I have never yet found an instance, or even heard of an artificially-coloured specimen being shown by a Northampton exhibitor. The two painted specimens at Leeds were Lizards, "one-year-off," or "out-of-feather" birds, being so doctored as to be made to appear as "yearlings." Before I had done with them the birds bore an odd appearance. I extracted the colouring from one side only, leaving the other side as a contrast. I regret I have not just now the name of the exhibitor of the Lizards. At both shows I posted them up with conspicuous cards in front of the cages.—G. J. Barnesby, *Derby.*

A YOUNG QUEEN WITH A FIRST SWARM.

With regard to the inquiry of "C. H. H.," page 197, I beg to say that it is quite a common occurrence for a young queen to leave with the first swarm, and scarcely a season passes without one or more instances of the kind amongst my own bees. I have already stated how they act in these cases in my former letter on swarming. I have had one this season, and as it may be of some interest to your readers, I will describe it. I had a storified hive which threw off a swarm; I caught the queen (the old one) and returned her to the hive, the rest of the bees following. I then ventilated it; but in ten days it swarmed again, also with the old queen, and I again returned it. Next day it did the same, and both queens came away, but were returned. They repeated the process the day after, and this time with a young queen, and were again put back next morning; they came out again with the old queen, and being again returned, issued twice more during the same day with young queens. As I was now beginning to be tired of so much swarming, I took half the combs, together with the supers and put them in the old hive's place, removing the stock hive with half its combs to a new stance, and by allowing all the bees to return to their old place they were not much the worse, and finished their supers as well as if they had never swarmed, and the old stock soon became strong enough to entitle it to be considered a good stock hive.—A Lanarkshire Bee-keeper.

ATTEMPTS AT BEE-KEEPING IN INDIA.

I am indebted to an unknown friend in the great Asiatic peninsula for a copy of a recent number of the Saturday edition of *The Indian Daily News*, from which I extract the following interesting article.—A Devonshire Bee-keeper.

Amusements of a Naturalist—Bees.

Bees that collect honey are found in almost all countries. And wherever Englishmen go to make new homes for themselves, if they find there are none, or none of the right kind to meet their wishes, they soon manage to get some from home. Bees occupy a very important place in creation, and perform very important functions in rendering fruitful the seed-vessels of vegetables and flowers. In New Zealand, it is said that the Clover taken from home and sown there produced beautiful crops of fodder, but no seed, till the English honey bee was imported. In India there is no lack of honey bees. There are three kinds that are especially interesting. The large bee, that constructs its combs on the boughs of trees, makes a comb about the size of the half of an ordinary cart-wheel. The bee is as large as a hornet, and its sting is fully as poisonous. I began amusing myself with this creature, but I thought it necessary to go about forming an acquaintance with it very cautiously. I thought it advisable, first of all, to understand the extent of its ability to produce hurt. I could pretty well judge of its honey-producing capacities from what I had seen of its comb,—3 inches thick near the bough upon which it was built, and indeed at times thicker if the bough were a thick one, and in the thinnest part where the breeding was carried on, fully 2½ inches in thickness. The upper part, that is to say, about a depth of 4 inches, was occupied with honey; and a full-sized comb would be about 3 feet along the bough, that is to say, comb filled with honey, 3 feet long and from 4 to 5 inches deep. A goodly quantity of sweet-stuff this, to be had for the gathering. The best way of gathering is to get a quantity of rubbish together, put it under the hive, or more properly the comb, and set fire to it in the evening. Bees cannot bear smoke, and there are most alarming tales told about travellers having made fires under trees in the daytime, without first looking up to see if the smoke might be any annoyance to any one up above. I remember an Arab horse-dealer once acting thus imprudently, and almost before his horses were picketed, the infuriated saurungs — that is the native name—began to sting the horses, and in the course of ten minutes every horse fled from the encampment, tearing like mad horses, at every point of the compass; the syces trying in vain every possible dodge but the right one to escape the infuriated creatures. Two of the horses that could not escape early enough died from the stings they received, and of the men several were ill for days. I did not know of the certainty of such cases as this, when I sought to make the acquaintance of the saurung honey-bee. The object I had in view was to domesticate them; and I knew I could not do so unless I could establish a sort of friendship with them. I found a fine large hive near my house, suspended from a large branch on a mango tree. My first object was to get hold of one individual bee by itself. I thought it safer to ascertain what could be done with one before I attempted a number. A marble from a goolail * soon brought down about half-a-dozen, and they were rather at my mercy in that state. I quietly proposed to one that we should make each other's acquaintance; he offered no objection, but when I took hold of his wings he protruded his sting. I said—"Exactly so! what is its value?"—and presented the little finger of my left hand in return. In an instant the bee was under my foot, for with a force which I had not counted upon, the sting was thrust home into my finger. Fortunately it pierced the

* Pellet-bow.

finger side-wise, and the thickness of the skin had saved me from the full effect of the poison; but the burning heat it had engendered in my finger, running right up my arm in an instant, quite satisfied me that I had better let well enough alone, and drop their acquaintance. I had carried an antidote with me, and as soon as I could get the cork out of the bottle, I put a good drop of ammonia well saturated with opium, on the place where the sting was taken out, and that soon gave me relief. I soon afterwards found that the honey collected by this large kind of bee is very coarse and often unwholesome. My readers perhaps will cry, Sour Grapes! Honour bright, however; what I say is correct.

The domesticated honey bee was always a great favourite with me at home, and indeed with my father and mother before me. I remember how often I used to get stung by them in our garden, when as a small boy I would disobey orders, and wilfully go to the hive and watch the little creatures, as they came home with their legs laden with little pellets of brown, green, and yellow pollen, which my mother told me was honey, but which I found when I caught one was not sweet at all, and therefore could not be honey—for which experiment I got a caning. I remember also one cold frosty night, as I got into the chimney corner, how all the household was thrown into confusion by some one rushing into the room, saying that there were thieves about, for that they had heard the rustling of their steps in the stubble field behind the house. There was at once a careful listening by all who were bold enough to venture out of doors; but all was quiet, not a footstep nor the least rustling was to be heard even in the stubble field. My father, however, thought he would make sure by walking round the grounds, and as he went into the garden, he thought in the starlight things did not look all serene about the bee-stall; and sure enough when he walked up to it, there was the heaviest hive out of five carried off. To follow the rogue or rogues on the way to the town was the resolution of all in an instant. But before they had gone half a mile from the farm-house, a man coming from the town assured them that he had met no one since leaving the town, and they all returned to the house. The search was recommenced the next day, and my father hit on the idea of going through the town, and looking after the contents of his hive, which he shrewdly conjectured would be there in some window exposed for sale. He returned home full of joy, for he had found his honey—he knew it was his—there could not be another such a hive, it must be his, the comb was two years and a half old, almost as black as ink, and the honey the best in the world. But the grocer in whose window it was exposed for sale refused to give it up—he had bought it. He did not know the person he had bought it of, but he had to come to his shop again the next night, which was Saturday, and if my father would come and wait inside, he would let him see who he was. All was arranged, and what a rise! The man was the very man that returning from the town, told my father he had met no one since leaving the town. The rest may be imagined. Nothing could be done. The other four hives, however, were at once chained down to their blocks.

I must have been about three years old when these circumstances occurred, and a big boy working on the farm put me up to a way of making experiments far more remunerative than the unloading of the little creatures laden with pollen. He showed me how to hunt out the humble bee, and to rob its nest. The plan was to take a bough of hazel, and thrash the poor bees to death, then pulling the poor creatures asunder at the shoulder, pick out the honey-bag, which then lay exposed. There was no amusement in this, and I never tried it twice.

And now to return to my Indian tale. As soon as I saw my error in hoping to domesticate the large sanrung, I was fortunate enough to find a hive of the true honey bee—like the one at home—located in a hollow mango tree in my compound. In my ignorance of the Indian bee, I concluded it was the same in its habits as our home bee, and therefore I prepared a box large enough to hold the bees of an English hive. The next thing to be done was to get them out of the tree. No one would help me, for all were afraid of the sting. With a good chisel and a hammer I soon managed to open a way into the hive, but while I was doing this the inmates had been singing *excelsior*, and had marched a full arm's length further up the tree. I took out all the combs, and then putting my hand up the tree as far as my arm could reach, I took out a handful of bees, and put them with the comb into the box I had prepared; but I was obliged to give this up, for as fast as I put the bees into the box they flew out again. I therefore yielded to necessity, and gave up that plan of proceeding. I then filled up the hole in the tree, as far as I could, with clay, and fixing my box up upon the tree, made such arrangements that the bees could only get in and out by passing through my box. I hoped by this means to get them into the box with their own comb full of young ones. I was disappointed however, for at five o'clock the next morning, they had all collected outside my box, and were evidently intending to emigrate as soon as their arrangements were matured. I managed to be beforehand with them, for I at once took a basket and whipped them all into it, by the aid of a grey goose-quill, and having got them there, I put a cloth over it, and kept them prisoners till the next morning. They showed their displeasure with my arrangements by beginning to fly out as soon as I opened their prison basket. I now caught sight of the queen, and picking her out, clipped her wings with a pair of scissors. Knowing that the hive was now at my mercy, I put them into a large glass dish-cover, such as is used for protecting cakes and such things. A small piece of new comb was fixed in its proper position, and another day in the dark was to produce great results. It did so, for the next morning on opening the covering I saw that the workers had repaired the comb where it had been injured, and the queen had laid a few eggs, so that I felt quite sure all would now be well.

The colony had become very small. I do not think there could be more than an ounce of bees all together. Bees are a very delicate people, and the least extra trouble or exertion kills them by hundreds. But small as the colony had become, for six days it was very quiet and prosperous, and they had become so accustomed to my investigations that I could take away the glass cover altogether, and the queen herself did not show any great signs of feeling the indignity if I picked her out and put her on my hand—the workers seemed most anxious, and usually one or two would accompany her upon my hand. On the seventh day, all my amusement seemed to be at an end; a servant came to tell me that my bees were on the wing. True enough, there they were, but what was the cause? And the queen without wings; where was she? The cause was at once evident; the ants had disturbed the new colony, and not being to drive back the enemy, they had vacated their works. The great question was, where was the queen? After hunting for her for some time, I found her with only two or three attendants, and one or two ants were upon her. I picked her up and put her in a safe place where the workers could get to her, and having secured her person, I set to work to drive off the ants. They had attacked the young grubs and had killed some of them, to my great distress. At length I got them all clear of the comb, and having put the feet of the table into water, I thought all would be safe for the future, and put the colony back again with their work. Things did not, however, at all please them. I fancy an odour of the horrid little ants was left upon the comb, for every now and again, an offended bee would buzz in the greatest anger, twizzling itself round and round for a second, and then rush off to another place. A great reduction in numbers had taken place, and at noon every day the few that remained took wing—I kept them in my room, where I could constantly watch them—but I usually interfered in time to prevent the vacation of the hive. At last, not caring much if I did lose them, I thought I would let them go on to the end, and see the result of the panic whatever it might be. The queen was evidently ill, and ceased to rush about as she usually does when there is excitement in the hive, uttering the long-continued *pe-e-e-e*. The workers all flew to and fro in and out of the hive, and to my astonishment one of the workers took up the queen, carried her out, and fell with her upon the grass. This was the end of the queen and of my colony of bees, for the queen died that same day, and I took no further notice of the workers.

I was not long left without other hives, for the natives of the city had taken an interest in my amusement; the extempore poets made and sang songs about me and my bees, and I had friends on all sides who daily brought me news of new hives. My amusements now formed a reason for morning and evening exercise, either on foot, or on horseback, or by buggy, and the boys of the city took great interest in the little folk that afforded me amusement. I now took a number of hives in hand; one I kept in the hollow tree where I found it. I brought it home from a distance of four miles on a cart at night. I filled up the aperture by which they passed in and out, cut off the timber which was not wanted, and so rendered the tree manageable. This hive did very well in its new locality, but I could only look at them going in and out, and amuse myself by observing their wonderful industry in working. A farmer who had heard of the eccentric sahib who tamed bees and made them understand him, came and offered me a good strong hive, that had shown decided musical propensities by taking up their residence in a tom-tom.* This was a great gift, and I went by moonlight, and brought it home with great pleasure. I so manipulated the earthen jar over which the skin was drawn to make a tom-tom of it, that I put windows in it, and so got free liberty to look at my friends by night and day. Then I made a door, and so in time got free admission to make experiments. After watching for hours during several days, I managed to see the queen laying her eggs, nearly close to the door. This was just the ticket. I secured her, and put her in a wineglass with a piece of muslin over it. And then I waited to see the result. Again and again I watched for three hours, and no panic, nor yet confusion; then I thought there was a slight change in the sound from the workers; then there followed a flying out and immediate return by some; their work ceased, and in place of its merry hum there was a sort of hushing sound; then a rush here and there in disorder, and finally a general rush to the aperture of the hive, and most of the bees took wing. I knew I was master of the position, so I waited patiently till the panic subsided, and when all was quiet in the evening, I opened the door to return her majesty to her throne and people; but as I was putting her in, I observed a lump of bees about as large as a hen's egg on the comb facing me. I, therefore, put the queen back to the wineglass again, while I examined this unusual appearance; and I was well repaid for my trouble, for the little creatures seeing their sad misfortune, had begun to make a large cell for a new queen. I at once decided to keep her majesty a prisoner, to see whereunto this thing would grow. By the next morning the cell was complete, and all attention was given to the grub out of one of the ordinary cells that was in it. The new cell

* Native drum.

was placed perpendicular on the face of the comb, and I have since observed that queen's cells are always in a perpendicular position. I could not afford to let matters go too far, because I should have lost my queen by so doing, and the new queen would have been unfruitful for a long time, if not altogether barren, inasmuch as she must have gone abroad among her neighbours for a royal consort. There were at that period no drones in the hive. Within three hours after the queen was returned the intended new queen was neglected, and the next day the disfigurement on the face of the comb had disappeared. As the spring came on, I saw the combs day by day enlarge, and immense numbers of drones—males—came out, and in due course queens' cells were formed upon the lower edges of the combs, to the number of twenty; and by the middle of February I had seen eight swarms fly off from this one hive. Some of the swarms were very small, and in the end the hive was so weak that moths got in and laid their eggs in the comb, so the few that remained were eaten out of house and home by the grubs of the moths, which burrowed the comb in every direction, filling them with cobwebs wherever they went.

Although I was much interested in my amusement, yet I must confess to great disappointment as to the commercial results. I had hoped that we might have nice little rows of bee-hives in our gardens in India, just as one can have at home, with results as sweet and as paying, but so far as I could see, the strong instinct for emigration and colonising in the Indian bee seemed to forbid such a result. As I could now get plenty of bees, I resolved for one good experiment in the interests of commerce. I thought if I could put five or six hives together, I should have a good strong one to begin the experiment with. So now I had a six-dozen beer chest prepared for a hive, and a noble hive it was. The thing to be done was to fill it with a working colony. A Mahomedan gentleman gave me free access to his forest and zemindary, allowing me to take any liberty I pleased with those trees that had bees in them; from cutting off a limb to felling the trunk. I selected my trees, and the first was an old jamman pollard. Two good bharrs (woodcutters) soon brought it down for me, and the bees being within 1½ foot of the bottom, I was able to reach them pretty well. But, do what I could, the bees would not remain in my hive, as fast as I took them out they flew back again into the tree. I ordered the tree to be split open in the middle—as soon as it was opened out, "horror of horrors," there lay coiled up a large khoreit snake, and every time my hand had gone in, it had gone over this snake. It makes me shiver when I think of it now, and the sight of those lookers-on who were with me is a picture on my memory still. My honest and good friend, the Mahomedan, would allow me to cut no more trees, unless I promised in future to see what sort of a nest I was putting my hand into. I of course gave the promise, and kept it. I saw my friend twenty years after the above, and he still retained the clearest possible conviction of the goodness of my kismut. May his shadow never grow less!

I got together six hives without any further trouble, and then, how were they to be united? I made short work of it, by mixing a solution of sugar and water, and poured it into the hive that was to be united with the bees already in the new hive. I easily managed to get the queen, and the workers were then taken to and claimed by the old stock as a matter of course. And thus I filled my magnificent hive. It was a sight to see them work. I had the hive in a house, with a hole in the wall for going out and in, and I had doors and windows for observation. I would have no tricks with these to interfere with the commercial results. My heart rejoiced, as day by day and week by week, I saw the combs grow and the inmates increase. To show their watchful care and strength, I may relate that a death's-head moth had the temerity to enter an air chamber I had made for ventilation; there he was waxed down to the board, and made a mummy as a warning to all such intruders. As the inmates increased in number, I was alarmed at the unusual heat engendered, and I did all in my power to cool them down. It was all useless; for the heat went on increasing, and the ventilators were covered with an immense amount of mixture that collected in large drops as the vapour condensed, and soon, to my utter despair, I saw combs forming for drones, and these of course were followed by queens' cells. I did all in my power to put an end to both, but the colony outwitted me, and one day I had the misfortune to see my splendid hive denuded of more than half of its population. I caught and killed the old queen who was leading them off, and the queen being killed the bees returned again to the hive. The excitement never subsided, and the next day many took wing again. I saw the bees were angry, but I did not expect the mischief which followed. I had a very tame, long-tailed, black-faced, white monkey—a longoor—and my angry bees stung him to death before I was aware of his danger. On the third day from the previous swarming, a new queen led them off again, and this time flew away at once. I now gave up all as useless and hopeless, and prepared for one final experiment, little suspecting the good fortune that awaited me.

I removed all the combs, except one very nice new little one, and sought for and removed the queen. My object was to see how long the workers would hold together and keep to the hive after losing their queen. At first, of course, all was confusion; but they soon began to collect pollen, though their wax was all wasted. And although the pollen was collected and brought home, very little skill was shown in storing it, and most of it fell in little oblong flakes at the bottom of the hive. After six days, I was surprised to find a number of eggs on the board at the bottom of the hive. I could hardly believe what I saw. I was quite sure there was no queen, and yet there were eggs. I made a closer search, and more astonishing still, nearly all the cells in the comb I had left them had eggs in them; not one egg in each, as the queen carefully lays her eggs, but in one I counted a dozen, and there was every proof of a most careless and indiscriminate laying. I was determined to give up any time and attention that might be required to fathom the mystery; and in a short time, I saw the common worker bees laying eggs. Of course I was most anxious to see what the final result of this new fact would be. I soon saw that the eggs were fruitful, for the little worm floating in jelly appeared in some cells the next day, and things went through their usual course to the closing-up of the cells. My patience could not wait for the flying insect to come out, and I opened a cell and took out a young bee nearly ready to come out and two days afterwards, I was gratified by seeing some half dozen little black drones fly out with their usual heavy buzz. This was highly satisfactory as far as it went. It was a fact, not before known, that the workers could turn out fruitful. There was no hope for the hive, for the males do not work. Nothing more was to be learnt, and my hive died out in a short time. And here was an end to my amusement with bees.

OUR LETTER BOX.

London Poultry Show.—Mr. Quick, 26, Henry Street, St. John's Wood, Hon. Sec. of the St. John's Wood Fancy Rabbit Society, expresses his willingness to co-operate. [We have so many letters advocating a metropolitan show, and tendering subscriptions, that we have no doubt if a committee were formed of well-known men, it could be effected without difficulty. We shall publish some communications on the subject next Thursday. Since the above was in type we have been informed that a meeting will be held on Tuesday, October 5th, at 3 P.M., at Evans's Hotel, Covent Garden, after the sale at Stevens's Rooms, when all who are interested in a metropolitan show are invited to be present.—Eds.]

Cochin Hen's Leg Ulcerated (*W. C.*).—Wash it with warm water, and then apply mercurial ointment daily, sewing a piece of linen rag over it.

Incubators (*M. Dene*).—We do not know the name. You had better advertise that you have one to sell.

Brahma Pootras (*H. W. G.*).—We have no information about the book.

Ground Oats (*Julia*).—Mr. Agate, Slaugham Mills, near Crawley, Sussex, grinds oats for poultry. If any one near you has a handmill for crushing oats for horses and would allow you to crush oats for your poultry in it, that would answer equally well.

Turbits (*T. W. Eckersly*).—Turbits were formerly preferred smooth-headed, then shell-crested, and now point-headed. You will obtain some point-headed birds in the way you propose to breed. The shoulders, so called, in Turbits should be of one colour, the rest of the bird pure white. The red-shouldered birds should be of a deep rich colour.

Pigeon Cankered (*Experientia docet*).—When the cheesy matter forms it is usually a bad case. It becomes better and disappears for a time, but always returns. For the snoring noise you mention, we always give a pill nightly, made of equal parts of tallow and camphor.

Goldfinches, &c., (*W. H. Horne*).—The direction you ask for is, Mr. E. Hutton, Garden House, Padsey, near Leeds.

White Turtle Dove (*May*).—The ordinary coloured pair of Collared Turtle Doves from which you have bred a white young one must have been in a former generation crossed with the white variety, for says Mr. Brent, there are such birds, "There is a very pretty and quite white variety which is, however, much rarer." Unless we greatly mistake there are some of these white Doves in the Crystal Palace.

Hive Tenantless (*A. S——k*).—The probability is that the young queen met with an accident during one of her wedding flights, or if your stocks are placed near together that she mistook her hive, on her return, and was killed. In either case there would be no means of replacing the lost queen, and the colony would gradually dwindle away until it became too weak to protect its stores which, therefore, would ultimately become the spoil of marauding bees and wasps.

Berkshire Pigs (*Ignoramus*).—We cannot inform you where they can be purchased, but certainly at Reading or Newbury market. We do not know what kind of pot you mean; we always employ small firkins.

Tobacco and Snuff (*H. M.*).—We know of no separate work on their manufacture. There is a lengthy notice of the subject in the "Penny Cyclopædia."

Tomato Jam (*A Lady Correspondent*).—"Take ripe Tomatoes, skin them, and put them in a moderately warm oven for several hours, until they will pulp without difficulty. Squeeze through a fine sieve, so as to obtain the pulp without the seed; to every 4 lbs. of fruit add 2 lbs. of loaf sugar, the juice of a lemon, and a little crushed ginger; boil in a preserving pan until the juice will set, put the jam into jars, and fasten down in the ordinary way.—J. Perkins."

POULTRY MARKET.—September 29.

Michaelmas is no longer what it was. Not one Goose is eaten now where a hundred were eaten formerly. Nevertheless, it is still a tradition, and at the recurrence of the festival, the supply was small this year, and full average prices were realised. It may be said of Geese as of Turkeys, that given equal and good quality, their value increases with their size.

From observations taken near London during the last forty-two years, the average day temperature of the week is 61 4°; and its night temperature 42.6°. The greatest heat was 77°, on the 9th, 1861; and the lowest cold 25°, on the 11th, 1860. The greatest fall of rain was 1.00 inch.

SMOKE, AND ITS EFFECTS ON PLANTS.

OF the various papers read at the Horticultural Congress at Manchester, there was one on the effects of smoke on vegetation, which deserves further inquiry, as smoke is an evil against which the best-directed skill can contend with only partial success, and notwithstanding the laws general and local bearing upon the nuisance, it is still on the increase. The Legislature may compel manufacturers to employ furnaces consuming their own smoke, but the chimneys of private dwelling-houses send it forth in quantities which yearly increase with the population and the accumulation of wealth. It is, too, somewhat unfortunate that in those places where steps have been taken to abate the evil, or at least to draw attention to it, the cause of vegetation has been but little urged in comparison to what has been said of human comfort and general appearances; even the claims of architecture have been put forth in advance of those of vegetation, but, fortunately, where injury is done by the blackening smoke, its effects being more visible on the vegetable world, those complaining have in certain cases obtained damages when their case has been investigated in a court of law. The number of sufferers who obtain redress in this way is so small that the majority of us are content to grumble at the grievance as one which cannot be helped. So, in spite of all that has been said and promised to be done, the smoke nuisance goes on increasing. Possibly some day a less costly and troublesome mode of diminishing its evils may be found, and its application to dwelling-house fires enforced by law, as it is now in some cases in those of factories and steam-engines; but until something of the kind be done, we must be content to try to mitigate the mischief by whatever means we can.

The injuries caused by smoke to vegetation have been long known, and remedial measures of many kinds suggested, but with little effect; in fact, the only practical cure for the evil is to divest the smoke of its hurtful tendencies, and to some extent this has been done, but not until much damage has been inflicted, not by coal smoke alone, which of itself is by no means so deleterious as many suppose, but when that smoke is tainted with the fumes of poisonous chemicals. Witness a plantation of fine large trees, mentioned by Mr. Green, near Widnes, on the borders of the Mersey, one-half of them or more standing like skeletons, the others fast approaching that condition, presenting a spectacle that cannot be looked at without some feeling of awe, so desolate is the scene. Even here vegetation of all kinds does not suffer alike, some plants struggle to keep up an appearance of life, while others are still less affected; but Mr. Green having described this, it need not be referred to again. The rising town of Widnes can hardly be expected to possess a horticultural society; on the contrary, vegetation shrinks from its borders, and its smoke-stained walls can never hope to be draped in the cheerful garb of floral beauty in the shape of climbers, or clad with the more sombre yet equally interesting Ivy. The smoke and vapours of its chemical works, however purified by all the efforts of skill and science, continue in some degree to escape, all the modes adopted to prevent injurious results being ineffectual. The evil, however, is certainly mitigated, and perhaps may eventually be more so, but the volatile character of some of the ingredients employed leaves small hopes of entirely remedying so subtle an evil. In the early days of such manufactories litigation often followed damages done to farming and other crops by the smoke emitted from chimneys, where soda and similar substances were manufactured. The leaning that jurymen had thirty or more years ago towards the sufferer is similarly carried out at the present day by those engaged in assessing damages for a railway accident, and the object, if not the justice, is certainly good. As regards the manufacture of articles causing a poisonous vapour, it sharpened invention, and caused the adoption of preventive measures: and in the case of railway accidents, heavy damages now and then are followed by more care on the part of the companies' servants. Probably coal smoke may eventually be no longer allowed to pollute the air, and shrubs and trees may again rejoice in that natural clearness which in the neighbourhood of towns they have so long been strangers to.

Smoke tells most disastrously on evergreen shrubs and trees, for those which are deciduous shed their foliage when smoke commences to be more abundant—namely, in the winter, and they do not put forth leaves again until the evil is somewhat abated in spring. Even in factories where the consumption of coal and other fuel is the same all the year round, the higher state of the barometer prevents the smoke doing so much harm as at other times, so that it is not unusual to see such plants as Wistaria sinensis, Laburnum, and Virginian Creeper, looking fresh and well against walls in the heart of London in May and the early part of June. The stems of these plants, however, are crusted deeply enough with the sooty matter. Some annuals of robust growth also thrive better than others in similar places. I have seen Tropæolums growing in very crowded quarters, and have also seen them within a stone's throw of the ocean; but ornamental shrubs capable of withstanding the smoke and dust of great cities are few indeed. The Aucuba is the best, and the appearance it presents there differs widely from that which it has in healthy country districts where the soil is of a suitable kind. Amongst trees that endure ordinary coal smoke best the Lime and Ash are as good as any, being both late in coming into leaf, and early in shedding their foliage; but the number of trees and shrubs that thrive well under such circumstances is so small that the most common are acceptable when they can be coaxed to grow. I have seen the common Elder made a pet of where scarcely anything else would live, and many a dull dusky corner is brightened up by a few plants of the common Marigold planted here and there without regard to order or arrangement; in fact, robust-growing annuals seem to do best under such circumstances.

Those having the management of shrubberies and similar

places in open country districts have but little idea of the dirt adhering to every branch and shoot of a plant growing where smoke prevails, and, I may add, even farming crops have in some degree the black stamp of the place they have been grown in. Hay-making is an employment which produces but little dirt on the clothing of those engaged in it, and the same may be said of harvest work; in fact, the handling of sheaves of corn has been supposed to have a cleansing effect on the clothing, but the reverse is the case in the smoky districts; there, both hay and corn impart their sootiness to the garments of those handling them. In families, also, when that evil day to the male portion of the community comes round—the washing-day, the prevalence of blacks creates no slight amount of irritation to the lady of the house, and consequently discomfort to all others, all owing to that everlasting smoke. This imparts its blackness to everything around, not omitting the animal creation, for do not the sheep in the London parks look smoke-stained?

With regard to mitigating the evils resulting to vegetation from smoke, I fear nothing can be done except abating the nuisance at its source, in other words consuming the smoke where it is created. Most likely this will be more strictly enforced where deleterious substances are manufactured, but even there it is difficult to obviate all mischief. Many years ago it was thought that very tall chimneys would carry the obnoxious gases so high as to become harmless by the time they reached the surface again, but this was found not to be the case, and other remedies had to be applied. Possibly some chemist among your readers may suggest cheaper and more effectual modes of purifying the fumes from manufactories, as the evil requires to be remedied as much as the deposit of sewage in certain places. Let as great a complaint be made of smoke and a remedy will follow.

In conclusion I would advise those planting groups of trees and shrubs in town squares and gardens to make sure of perfect drainage; indeed, a dry, sandy, or gravelly soil would seem best, for plentiful washings of water would do no harm to the roots; and as the water-supply of towns is generally so ample as to admit of a bath being frequently given, much good will result, especially if large quantities of water can be used without soddening the ground, which would be the case if the soil were too stiff. A good washing now and then might enable many evergreens to thrive which now will not do so, but it is vain to expect they will compare with those grown under more favourable circumstances. Once let the smoke nuisance be abated, and a better state of things will follow.—J. R.

NOTES ON ROSES—THE MANETTI STOCK.

I offer a few notes on the Roses in cultivation here; but before doing so, a question having arisen in your pages about the Manetti stock, the editorial request must take precedence.

My Roses are known in this neighbourhood, and the reason they have become so is, I suppose, that they are sufficiently well grown to attract attention; but the mode of growing them has really been the cause of their receiving the notice bestowed upon them, and this is due to the Manetti stock more than any other assignable reason. The soil is of the lightest description; and the attempt to grow Roses upon it successfully, or rather satisfactorily, after several years' trial with the Dog Rose as a stock—that is, as standards of whatever height, resulted in disappointment. Hence followed the wish to try some other method, and for the last eight years the gradual substitution of the Manetti for the Briar has, with very few drawbacks, more than answered the expectation formed of it.

The question of Manetti *versus* Briar has been so frequently ventilated in these pages, that it is with some surprise that I see it again brought forward. The short reply of Mr. Radclyffe in page 247 literally contains *multum in parvo*. There is no need to repeat more than an emphatic endorsement of what is there stated. The Manetti stock is not only *not* an imposition, but is also a great boon to rosarians who have light and poor soils in which to cultivate their Roses; otherwise they must give over the attempt, the propagation of Roses on their own roots being so slow and uncertain as to deter the most persevering. If the Manetti stock has proved successful in a commercial point of view, it is owing to the increasing confidence in it, and the growing appreciation of its merits; and it is not too much to say that at least the majority of those who have adopted it with success will ever regard with the highest respect the name of Mr. Rivers who introduced it, and of Mr. Radclyffe who has so long and ably urged its adoption.

In giving a few jottings on Roses, chiefly of the older kinds, I shall omit mention of many varieties which are now thought not above mediocrity, but which, nevertheless, I have not yet sufficiently hardened my heart to cast out. This process of hardening, I suspect, is with many of us somewhat slow, and with me it is a one-sided process too; for however slack I am in rooting out plants that have cost some amount of care and yielded only a moderate degree of gratification, but which after all are below our standard of excellence real or ideal, I am apt to complain loudly to some of our principal Rose nurserymen of their overcrowded catalogues.

A Rose that produces, season after season, under all circumstances, an abundant or fair supply of bloom of good colour, form, and size, with a vigorous habit of growth combined with hardy constitution, must be marked first-rate. Such are Charles Lefebvre, Jules Margottin, Gloire de Dijon, and Céline Forestier; and very closely following them, for it is difficult to draw a sharp line of demarcation, are Senateur Vaisse, Madame Victor Verdier, Maréchal Vaillant, Marie Baumann, and Prince Camille de Rohan. These I rank as the very best of Roses on account of their constancy every year. Senateur Vaisse does not grow so strongly as Madame Victor Verdier, but is splendid in colour, and scarcely surpassed in form. Nor is Prince Camille de Rohan so perfect in form and habit as could be wished—in fact, it is rather slovenly in the latter respect. Gloire de Dijon and Céline Forestier grow best on the Briar; all the rest have been far superior on the Manetti stock, although Charles Lefebvre, Maréchal Vaillant, and Madame Victor Verdier will make good heads as standards even in this light land.

Those Roses of the Remontant class (Hybrid Perpetuals), which are constant every season, are still few in number; and if the abovenamed are not all—and they are not—it will at least be conceded that they are the best. Very many that have proved good in one season too often show defects in the succeeding one; and some disappointment has been occasioned this year by several prominent failures, as Alfred Colomb, Marguerite de St. Amand, John Hopper, Pierre Notting, and Leopold Premier. Another year will probably remove the disappointment, and they will again hold a first place. Not quite so variable, but still showing evidences of changeableness, are Camille Bernardin, Maurice Bernardin, Beauty of Waltham, and Adolphe de Rothschild, all of which I rank among our best crimson scarlets.

Of the darker crimson Roses, none have been more beautiful in rich glowing colour this year than Lord Macaulay, Horace Vernet, Duke of Wellington, and Xavier Olibo. The first two might almost be ranked among the very best, being quite full and of fine form, in addition to having intense colouring. The other two are remarkably attractive, but not quite full; and Xavier Olibo has here frequently been rough and unfit for the exhibition stand. Somewhat inferior to these, but yet good, have been Jean Cherpin and Souvenir de Comte Cavour, while Duc de Cazes and Monsieur Boncenne of like colour have been utter failures.

Duchesse de Caylus and Exposition de Brie have been the best of what may be called the crimson carmines; the former rather small but of exquisite shape; both are tolerably constant during successive seasons. Madame Caillat and Dr. Andry have been invariably good, but appear rather dull in colour by the side of the brilliant kinds named above. Antoine Ducher has not at all realised the pompous description of it when first sent out. Thorin, too, is surpassed by others of its colour.

In no strain of colour have shortcomings been more conspicuous this season than in the rose-coloured varieties. Comtesse de Chabrillant, La Ville de St. Denis, Comte de Nanteuil, and Gloire de Vitry have not expanded their blooms with the certainty that has hitherto characterised these kinds, although considered among the best of their colour. John Hopper, as before mentioned, has too often put on a rusty coat, which spoiled its good looks. Madame Fillion is a brilliant Rose when it can be grown, but here it fails, it will not grow. Two indifferent blooms from three plants in one entire season are not enough to satisfy the most moderate rosarian. Anna Alexieff is a very pretty garden Rose that blooms abundantly, and has this year maintained its character. I still keep Madame Hector Jacquin on account of colour and distinctness of form, although defective in some respects—for instance, not being sufficiently remontant.

Of light pink Roses, Mdlle. Thérèse Levet has been superb. I have not had it long enough to pronounce a decided opinion, but apparently it bids fair to rival Marguerite de St. Amand, unless this beauty should prove more constant than she has this year. Charles Verdier will not open. Charles Rouillard and Comtesse de Jaucourt are worthless in this light soil, although

they have had high cultivation. Semiramis has, on the other hand, been very beautiful, and by no means showing the coarseness that has been attributed to it, such as is often seen in Madame Boll, which I have almost discarded.

Light and white Roses with the constitution of some of the crimson kinds are still a desideratum. La Baronne de Rothschild appears to be a step towards it. Caroline de Sansal is still one of my best Remontants, and Mdlle. Bounaire the most beautiful—it grows satisfactorily here. Souvenir de Malmaison and Acidalie are yet unsurpassed; the former has bloomed profusely throughout the summer. Mrs. Rivers, Queen Victoria, and Madame Vidot are Roses that always please but never satisfy the rosarian, unless he has favourable soil for their culture. I doubt whether Miss Ingram will do more. A word of praise may be said for Princess Mary of Cambridge, Mdlle. Annie Wood, Mdlle. Mary Rady, William Griffiths, and Baron Gonella.

Of newer kinds there is not much to say. La France is pretty and desirable, perfectly distinct, and free-blooming. It will be seen whether this variety will produce a progeny leading a step out of the "rut." Marguerite Dombrain will not hold a prominent place long. Merveille d'Anjou, Madame Barriot, Madame Pulliat, Baron Haussmann, Souvenir de François Ponsard, Souvenir de Mons. Boll, President Willermoz, and Curé de Charentay have as yet shown nothing to recommend them—more than one of them quite the contrary. Madame Marie Cirodde is a most vigorous grower with large rough flowers, the reverse of the petals more deeply coloured than the upper surface, a peculiarity that few besides Rose critics will notice. Neither Paul Verdier nor Miss Ingram are Remontants, and though very good, by no means surpass those grand old favourites Charles Lawson and Blairii No. 2, which they somewhat resemble but will never supplant.

There are a few Roses that yield, year after year, flowers that "when viewed aright must be seen on the living plant," but are apt to be pooh-poohed by many Rose-growers. In this category I place Empereur de Maroc, whose compact velvety maroon is not yet equalled by any other Rose. Eugène Appert, again—observe the young foliage of this Rose with its peculiar but delicately reddish-tinted leaves; the rich scarlet of the flower seems to have infused itself not only into the leaves, but into the very wood of the plant. Général Jacqueminot, too, shows his ruddy petals conspicuous among a host. We all like to see the colour of a Rose and to inhale its fragrance—the "old General" has both. Triomphe de Paris is a favourite, because with Gloire de Dijon it is the first to expand its flowers in May, and the last to go out of bloom in November.

I have now contributed my quota. May I ask others to do the same, that we may compare notes?—Adolphus H. Kent.

CUCUMBER CULTURE.—No. 10.

Insects.—The most common and hurtful is *thrips*. There is no better remedy than fumigation with tobacco. A calm evening should be chosen; the lights covered with mats or canvas, so as to keep the smoke as long about the plants as possible, and the foliage should be dry, though the floor and other parts of the house should be wet, to counteract the drying influence of the fumigation. Care should be taken to deliver the smoke cool, and not directly upon the plants, if possible. If they are in a pit or frame, there will be no necessity for any moisture beyond that which arises from the soil. The atmosphere of the place should be filled so full of smoke that the foliage cannot be seen from the outside. The fumigation should be repeated on the next night but one, keeping the place close and moist in the interval, but avoid syringing the plants. Fumigate again whenever the insects appear, and before the foliage is to any extent damaged.

Red spider should be guarded against by maintaining a moist atmosphere, and by other preventive measures. The walls and hot-water pipes should be coated with sulphur brought to the consistency of paint, by the addition of a solution of 4 ozs. of soft soap in a gallon of water. This should be put on when the plants are turned out, or soon afterwards, and the application may be repeated when the sulphur ceases to give off its fumes. The evaporation troughs may be kept full of guano water of the strength of 4 ozs. of guano to the gallon, and the floors sprinkled with the same, but of a strength not exceeding 2 ozs. to the gallon of water. Another good preventive is syringing with soot water made by stirring up a peck of soot in thirty gallons of water, using the clear liquid.

In cases of actual attack the above measures should be resorted to, for they are remedial as well as preventive. Pipes should be coated with sulphur after they are heated to 160°, or the water heated to between that and 180°. Repeat the painting until the house is quite full of sulphur fumes, and the air becomes oppressive to the lungs. After coating the pipes with sulphur, it is well to sprinkle them lightly with water for a short time, so as to fill the house with vapour. The house should, of course, be shut up closely, and in the morning a good syringing should be given. This, repeated a few times, will effectually destroy red spider.

Plants in frames are not so easily freed of red spider. I find, however, that coating the inside with the sulphur paint (not allowing it to touch the leaves, as every spot on them made by the brush will certainly destroy that portion, on account of the soft soap with which it is mixed) will destroy red spider, if the frame be shut up early in the afternoon, and a gentle sprinkling of water be given. The temperature, however, ought not to exceed 100° after the frame is closed. In severe cases, the plants may be syringed with sulphur, dissolving 1 oz. of gum arabic in a quart of water, and then adding sufficient flowers of sulphur to bring the whole to a paste, which, when well stirred up in three gallons of water, may be syringed over the foliage between 3 and 4 P.M. on a fine day, and the lights drawn on closely. On the following day the plants may be lightly sprinkled with water at the same time, and the lights closed. To prevent the insect spreading, the leaves worst infested should be picked off and burnt, thus not only destroying great numbers of the perfect insect, but a host of eggs. These remarks apply to thrips as well as to red spider.

Aphis occasionally attacks the Cucumber plant; destroy it by fumigation with tobacco smoke.

Diseases.—*Mildew* sometimes makes its appearance. It yields to dusting the leaves, stems, and fruit on all sides with flowers of sulphur. In houses the readiest plan is to paint the pipes with sulphur, as for red spider.

Canker.—This is not very common, and is a result of too great moisture in the atmosphere or soil succeeding continued dryness. It mostly occurs when plants are over-vigorous. It is confined to the stem, generally near to the collar of the plant—a part which should be kept more thin of leaves than the other parts, and not wetted in watering. The remedy is to clear off the leaves that deprive the cankered stem of light and air, and not to wet it. No more water should be supplied than is needed to keep the foliage fresh, and an abundance of air ought to be given. The parts affected ought to be rubbed until dry with quicklime, and then dusted with finely-powdered dry charcoal, repeating this proceeding as long as the ulceration continues, and if it cease for a time, it will return in a few days, unless the treatment be less forcing. Cankered plants are not long-lived; indeed, it is rare that their existence can by any mode of treatment be prolonged beyond a few days or weeks; but in most cases the above treatment will preserve the plants until the fruit be swelled off, and others can be raised to take their place.

Canker is sometimes caused by the use of unsuitable soil. Very rich soils induce excessive vigour, necessitate frequently stopping and thinning the shoots, and both stems and fruit are attacked by canker. Neither Cucumbers nor Melons do so well in calcareous soils as in some others; soil from freestone is in every respect preferable to that overlying limestone.

Gumming or Extravasation of Sap.—The causes of this in the Cucumber are excessive vigour, and the contraction of the sap vessels. If an excessive amount of nourishment is furnished by the roots, the sap being formed more rapidly than the vessels can take it away, there is an exudation of gummy matter both from the stems and fruit, and the latter become deformed and valueless. The only remedy is to prune little, to give more air and warmth, so as to assist the circulation, to remove part of the soil, and replace it with some which is poorer or more sandy. Gumming is most common with plants in frames late in the season, when the roots are in the dung of the bed. The atmosphere is then more moist, and the heat being less, the elaboration of the sap is much slower than in summer under powerful sun. I have known a lining of hot dung to the sides of the bed and frame entirely put a stop to this disease, the plants being watered sufficiently, but no more. When contraction of the sap vessels is the cause, there is a swelling of the stem or fruit immediately above the place of discharge. It is usually a result of weakness, and there is no remedy but stirring the surface soil, and replacing it with fresh, the application of more warmth to the roots by linings to the bed, or bottom heat, and a careful reduction of the shoots—it must be done cautiously, or we may have extravasation in

its worst form. The first cause of gumming is known by the over-luxuriant growth, and the second by the comparatively slow and weak growth.

Bitterness of Fruit arises from an imperfect elaboration of the sap. The neck is invariably more bitter than any other part of the fruit. The evil is in most cases removed by an increase of temperature, and keeping the shoots less crowded, so as to expose them more fully to light. The quicker the fruit is swelled the sweeter, crisper, and more wholesome it is.

Plants Declining.—All the evils named are insignificant compared to that fell disease which of late years has been a cause of great anxiety and annoyance to the Cucumber-grower. Plants that appear healthy and are producing or promise good crops, go off in a day or night. It has been ascribed to soil and numerous other circumstances. I have tried various means to avert the disaster—such as fresh soil, change of seed and variety—without effect, the plants dying off as before, and without any other warning than their appearing to be at a standstill for a few days; the leaves not enlarging, the shoots not elongating, nor the fruit swelling as they ought. Cuttings taken from plants in that state perish like the parent, and the roots do not survive the tops. It attacks plants in houses and in the open ground, in poor soil and in rich, in dry soil and in wet. When it once appears nothing seems to arrest its progress. Like the Potato disease, it comes again when we think we have found out a way of warding off its attacks. All we know of the disease is—First, it rarely attacks plants from October to June, seldom those grown in pots or from cuttings, and not often until the plants are of a size fit for bearing, but most commonly when they are beginning to fruit. It is most prevalent from June to September, and especially in the last-named month. Fresh, sweet soil not of a rich nature seems least favourable to it; rich and wet soils appear to encourage it. Secondly, it generally makes its appearance when, after dry hot weather, the atmosphere becomes cool and moist and continues so; the vegetation of the plants then becomes inactive, the leaves wither, and the plants die. Thirdly, it does not confine itself to the Cucumber, but extends to the Vegetable Marrow, whose leaves go off in spots like those on Potato leaves, unaccompanied, however, by the peculiar odour given off by a field of Potatoes.—G. Abbey.

AUTUMN CROCUSES.

Why is it that we see so little of those charming plants the autumnal Crocuses? I have tried to procure some of those choicest of Nature's gems in days gone by, but I tried in vain. Some time ago I made application to a leading firm for a supply of some of those enumerated in their list, but the reply, "We are sold out," reached me instead of the roots. Time went on, and again I applied, but, judge my surprise, when I expected to have received my parcel of bulbs, in their place I received the information, "Not in the trade."

There are many named kinds of Crocus said to be autumnal, but how seldom are they seen, and how difficult to procure!

Beautiful as the vernal varieties are, those of the autumnal race, if cultivated to half the extent of the former, would more enliven our borders declining in beauty during the autumn. I am inclined to think they belong to that much-neglected race of what are called border flowers, and if brought into more general cultivation would be equally interesting to many cultivators. Sir J. E. Smith, in his "English Botany," tells us that Crocus sativus is naturalised, but I have not met with it as yet. It is by some called Crocus autumnalis. Crocus nudiflorus he names as naturalised too, but it is said to be rare, which no doubt is true.

Native or not, Crocus nudiflorus is an acquisition to any collection, and ought to be in each and all. Crocus speciosus is said to be rare. I am inclined to think it must be both local and rare. How often will the collector of novelties take the last root that can be found of any choice but rare plant? Pity it is that we should be so bent on destroying a station of anything of the kind. Some time now past I was one of a party out collecting; we came across a rarity in the neighbourhood, when it would have been carried off root and branch, but I pleaded for future generations, and prevailed, in hopes that many more of the same kind might spring up; but I was chagrined to find the next party that came secured it, one saying I should look after myself, and let others do the same. "Bear and forbear" is a grand motto, and is as applicable to plants as to animals.

In looking over the names enumerated in the "Cottage Gardeners' Dictionary," I find twenty or more Crocuses coming from as many different places, said to flower in the autumn, and exhibiting nearly as many shades of colour. My mind rests upon such a sight as twenty or thirty kinds of Crocuses in bloom in September and October with a feeling I cannot explain, but I should like to see such a sight in reality. The question, however, arises, How are we to get them? Not many of us have the means to go to Naples, for instance, nor yet to Florence, to say nothing of the Cape, the Continent, Asia, Africa, or America. Seldom do we meet with half-a-dozen kinds!

There is another desirable plant for autumn, Colchicum autumnale, which much resembles a Crocus, showing its lovely pale flowers among the grass in limestone districts, and which may be procured much more easily than Crocuses. It will grow in almost any soil or situation, and is an acquisition to the borders in September. The double variety is a little later, but is more showy than the single kind.—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

IRESINE HERBSTII.

Much has been said and written on the merits and demerits of this plant as a bedder, and after having been run down as good for nothing, it has generally become acknowledged as a valuable plant. But how little has been said of it as a decorative plant! Yet I am assured that it is a very excellent one for this purpose. I saw the other day at Messrs. Windebank and Kingsbury's, at Southampton, a plant at least 6 feet high, and Mr. Kingsbury told me that when in bloom it is a most beautiful object, blooming something like Humea elegans, but more elegant even than it, and that it continues in flower from October to March in any house from which frost is excluded. It may be worth notice, then, by those who wish to have decorative plants during the winter months.

May I take the opportunity of tendering my thanks to those fellow rosarians who have kindly taken my hint, and written their experiences? I may have something to say about them by-and-by, and in the meantime would say, Let none of those who grow and love the Rose be deterred from writing what he knows about it by the fear that he is writing truisms; we want information, and from all sorts and conditions of soil, climate, &c.—D., *Deal.*

THE CLIMBING DEVONIENSIS ROSE.

Though not a Rose-grower but only a Rose-lover, I may venture to quote my own small experience of the growth and management of the so-called Climbing Devoniensis, the future of which puzzles my worthy friend, "Y. B. A. Z." Ten years ago I planted against a paling, 9 feet high, a plant of that Rose grafted on the Manetti stock; it was, of course, planted some inches below the scion. After a while it began to grow vigorously, but did not produce more than some stray blossoms; nevertheless, it was allowed to grow as it liked, its only pruning being the tying-in and bending down its straggling branches. One year I had a shoot at least 18 feet long which was not interfered with, and it is now nearly 3 inches in diameter. The result has been, that two years ago I had at least four hundred blooms, and branches laden with blossoms were cut off for home exhibition. This year one day one hundred lovely buds were gathered, and two days afterwards sixty were gathered, leaving scores for future plucking. These were independent of the continual gatherings for weeks, as we always expect to find some buds during the summer months, though its bloom is not nearly so continuous as that of its neighbour, the Gloire de Dijon, in the praises of which no one can be too eloquent. If "Y. B. A. Z." leave his strong shoots alone and do not tip them (as the winter will do this effectively), but gently bend them when they will bear handling, he will have more blossoms than he will know what to do with; though this is scarcely possible, as his lady friends will fully appreciate Devoniensis buds in any stage.

In contrast with this luxuriant growth, I may mention that at the same time I planted a Devoniensis originally budded on the Briar. This was planted with equal care, but the stock was stagnant, and though the graft was some inches below the surface, the Devoniensis has never attained any vigour, nor thrown up shoots more than 20 inches high, and it only continues to live, though it has grown more this year than it has previously done. Never remove a tree, especially a Rose tree, if there is any growth, is my limited experience, for after a

while the most unpromising will probably start into vigorous growth if a free-growing sort.

It is unkind to be glad to find other persons are as badly off as yourself, but the testimony of so many correspondents about the uncertainty of Maréchal Niel, tells me that the fault was not mine that four plants most carefully tended have ceased to live. "Try again" is my motto, for it is such a beauty that any pains are well bestowed to obtain a good plant. Last year our best Rose-grower, with his own hands, to prevent disappointing me, put into Devoniensis and Gloire de Dijon stocks at least a dozen buds, not one of which succeeded. When it takes to the soil it will grow nearly as strongly as Devoniensis. In Mr. Pavitt's garden here, whence originally the Climbing Devoniensis was procured, Maréchal Niel grows more freely than any modern Rose, and his oldest tree is a sight, having many shoots upwards of 6 feet long, this year's growth. He cuts trusses of bloom, that show how well he understands its management. From him I learnt that if you wish a Devoniensis to grow strongly and retain its so-called climbing character, insert buds from a free-growing branch. If, on the other hand, the future tree is to be of a shorter and more compact character, select buds from flowering and more stumpy side branches. I have no doubt that this rule is of almost universal application; it is so in the case of Pear grafts.—J. S. B.

OAK LODGE,

THE RESIDENCE OF JAMES MCHENRY, ESQ.

THE grounds, entered by a carriage drive from the Addison Road, Kensington, are of no great extent, but afford striking evidences of wealth and luxury. The forms and figures are all gently rounded off and unite softly with each other. Lawn and gravel, shrub, tree, and flower, with all the less common and more costly appendages appear to belong to one another, and to fit into the place in which they occur. The idea of size is not to be realised within narrow limits by mere simplicity; it is indefiniteness, giving the eye a number of points to rest upon and recesses to explore, and giving the imagination a field for its active exercise, that produce the required result.

The conservatory attached to the house is furnished with a large mirror set in an ornamental door-like frame which, seen from the drawing-room, reflects and gives the appearance of increased length and breadth to all the statues and floral ornaments the conservatory contains. Of these may be noticed Dicksonia antarctica, 6 feet high in the stem, with fronds 10 feet long, various other Ferns, Camellias in pots, &c., and the walls are covered with Plumbago capensis, Lapageria rosea, Passiflora Impératrice Eugénie, &c. Marble statues occupy niches, and china vases are tastefully arranged on the floor.

On the garden or east front of the house is a terrace walk with vases filled with flowers on the balustrades; and the narrow borders around, edged with stone, are planted with Flower of the Day Pelargonium, with a bordering of the blue Lobelia. The view from the house comprises the lawn, lake, rockwork, clumps of trees, and single specimens, so disposed as to produce variety without intricacy. As you pass along, flower beds come into sight, with the lake and rocks, the latter surmounted with shrubs and tall flowering-spikes of Yucca filamentosa, backed with two large specimens of Wych Elms, and in the distance by Holland Park woods.

A vista to the right is composed of nine flower beds on grass, four circles of which are filled with Calceolaria Kayii in the centre, then Tom Thumb Pelargonium, edged with Cerastium tomentosum; two oblong beds with Christine Pelargonium, edged with Crystal Palace Tropæolum; two beds with Bijou, edged with blue Lobelia; and the centre bed contains Coleus Marshalli and C. Verschaffelti, edged with the Golden-feathered Pyrethrum. In various vistas and recesses around the lake that open up to view as you pass along the serpentine walks are flower beds. One is planted with yellow Calceolaria and Tom Thumb Pelargonium, edged with blue Lobelia; another with Calceolarias and Stella Pelargonium, edged with Gnaphalium tomentosum; small circular beds with Mrs. Pollock Pelargonium, edged with the Golden Feverfew; and a circular bed divided into four parts, two of which were planted with Purple King Verbena and two with Flower of the Day Pelargonium, edged with Golden Feverfew.

From a seat on rising ground beyond the ornamental rustic bridge, a fine view is obtained of the lake, the rockery, the Ivy-clad church of St. Barnabas on one side, and on the other a portion of the lawn, rising up like an amphitheatre to the distant shrubs, backed by the woods of Holland Park. The lake itself, though small, is a source of variety, with its beautiful changes of aspect, and the reflections of lawn, plant, and sky which are so softly mirrored on its glassy surface. The pleasure ground of a mansion can scarcely be considered complete unless it contains a piece of rockwork, either natural or artificial. There are, however, few persons who can imitate natural rock successfully. Rocks where they exist naturally, or where artificial ones are judiciously introduced, tend greatly to beautify a piece of water. What can be more appropriate than rocks for the high banks of a lake? Here there is an excellent example of rockwork, furnished with all the best sorts of shrubs too numerous to name, Ivy and other climbers overhanging the rocks, and from a seat in front of a waterfall a pretty landscape view is obtained. The rockwork is on a large scale, not one continued line, but broken at intervals, in one part lost beneath the surface of the earth, and again rising in another part and resuming its sinuous form. The method of making artificial rockwork is to have every stone arranged to suit the eye, and the interstices are then to be filled up with any kind of rough mortar. Of course, fissures and similar places intended for plants which are to cover the rock must be left open, so that the roots may penetrate to the soil beneath the stones. The next operation is to daub the whole mass over with Roman cement.

A Beurré Diel Pear tree growing high above the rockwork, with a few Apple trees interspersed among the shrubs are conspicuous. I have often thought that there is no species of tree that produces greater variety of form than the Pyrus tribe; indeed, it would be difficult to imagine any form of deciduous tree that may not readily be found in one or other of this interesting tribe. Fruit trees in shrubberies ought to be more abundant than they are, for they are quite as ornamental as most of our deciduous trees and shrubs at present in use, both in spring when in bloom and in autumn when laden with fruit, for who is there who does not admire either Apples or Pears? For villa and small gardens in general there is nothing equal to them for ornamental planting, either as standards or bushes, intermixed with a few evergreens, to give the garden a finished appearance in winter.

If fruit trees, as in France, were planted along the high roads and in the hedgerows instead of the useless pollards that now disfigure them, we should have an abundance of useful fruit and fewer complaints of pilfering. There are public pathways through many orchards in Kent, and through the market gardens in the neighbourhood of London, and there are but very few complaints of the loss of fruits or vegetables.

The specimen house, 70 feet long by 20 feet wide, contains about seventy Indian Azaleas. About fifty of them are from 2 to 5 feet in diameter, and 6 feet in height; not one-sided, but cone-shaped, and feathered all round from bottom to top.

Running east and west are two houses, each 120 feet long, with a promenade walk and borders between, furnished with handsome, spiral, young Box trees and other shrubs. The first range is divided into early and late vineries and Peach houses. The wood of the Vines in the early house is as fine as could be wished, and in the late house there is a splendid crop. The Peach houses are fine examples of good management, which was proved this year by a prize at the May Show of the Royal Horticultural Society. The other range includes the stove, intermediate house, and New Holland house. In the stove were two splendid specimens of Allamanda grandiflora, with between seventy and eighty expanded blooms on each, also Croton pictum, C. variegatum, the Cocoa-nut Palm, large specimens of Ixoras, Bougainvillea glabra, covered with its beautiful pink flowers; Franciscea calycina, and Eucharis magnifica, which had borne upwards of one hundred rose-coloured racemes from 18 inches to 2 feet long.

The other houses contained large specimens of Clerodendron Thomsonæ Balfourianum, Azalea sinensis, besides many varieties of Azaleas and Ferns. In the New Holland house was a miscellaneous collection of Fuchsias, Pelargoniums, Boronias, &c. To the north of the house is a bank overlooking the lake, which is planted with a row of Irish Yew, then Aucuba japonica, then a row of Berberis Aquifolium, edged with Hypericum—a succession of shrubs as here displayed most suitable for embankments.

On the north side of a hedge in the kitchen garden are temporary pits where the large specimens of New Holland plants are placed in the summer. Amongst them I noticed an Erica depressa, 5 feet high and 4 feet in diameter; Genetyllia fuchsioides, G. tulipifera, Erica colorans tubiflora, 4 feet in diameter;

very large specimens of Erica Cavendishii, Pimelea spectabilis, Chorozema varium nanum, Pleroma elegans, Pimelea Hendersoni, Phænocoma prolifera, &c.

The gardens, pleasure grounds, and houses are kept in first-rate order by the persevering and excellent head-gardener, Mr. Wilkie, whose name is to be seen every year attached to some of the first prizes awarded to the collections of plants at the great metropolitan shows.—W. Keane.

ROYAL HORTICULTURAL SOCIETY.

October 5th.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. Prizes were offered for three bunches of Chasselas Musqué Grapes, for which there were no competitors; also for three bunches of Muscat Hamburgh, for which Mr. Osman, Great Stanmore, was the only competitor. These were grown in a conservatory, and were not favourable examples, and hardly ripe. They were awarded a second prize. Mr. Stevens, of Trentham, was the only competitor in the class for Black Hamburghs, or Frankenthal. His were three splendid bunches in size, form, and colour, and received a first prize. Mr. Wattam, gardener to C. Longman, Esq., Shendish, Hemel Hempstead, sent for competition in the class for White Muscat of Alexandria three noble bunches of that variety, which were so superior, that in addition to the first prize they were awarded a first-class certificate. There was a strong competition in the Alicante class, which brought out exhibitions of very large and handsome bunches. The first prize was awarded to Mr. Egerton, gardener to Countess Waldegrave, Strawberry Hill, for three bunches weighing 15 lbs 15 ozs., beautifully grown and coloured; the second was taken by Mr. Latham, gardener to Messrs. Bertram & Roberts, Rockhill, Sydenham, for very large but not so even bunches; and Mr. Lynn, gardener to Lord Boston, had three good bunches, but not so well coloured, and it received a special certificate. In the class for three bunches of any new or recent variety, Messrs. Standish sent three fine bunches of Royal Ascot, with fine, large, jet black berries, which received the first prize; and the second was awarded to Royal Vineyard, sent by Mr. Baxter, garâcner to C. Keiser, Esq., Broxbourne. In the class for the best collection of Grapes named, there was no competition.

For Messrs. Lee's prize of £5, there was only one exhibitor. Mr. Stevens, of Trentham, sent three bunches, two of which were small, and ripe; the third a large, handsome bunch, but very unripe; and as the unripe bunch disqualified the exhibition, it was decided that the prize should be repeated, of which due notice will be given in the schedule for next year.

Mr. William Paul sent a collection of ten seedling Grapes, some of which were of excellent flavour, and the Committee commended 6, 11, 12, 10, 7, 4, and 15. Mr. James, gardener to Lord Dartmouth, at Patshull, sent two bunches of a seedling Grape, the berries of which may be called enormous; they are oval, white, firm-fleshed, and with a very rich and agreeable flavour. The Committee highly commended this admirable Grape, and recommended Mr. James to persevere in the cultivation of it, and send it up next year. Mr. Wells, of Southend, received a special certificate for a fine basket of Black Hamburgh grown in a ground vinery.

Mr. Bateman sent a basket of Bananas, Mangos, and Cape Gooseberry. The first were excellent, but the Mangos were over-ripe, and the Cape Gooseberries were scarcely ripe. Messrs. Stuart & Mien sent a seedling Tomato, which proved to be the Red Plum-shaped. Messrs. Carter & Co. sent a collection of Tomatoes, including the new American General Grant, Yellow Cherry, Red Currant or Solanum racemigerum, and one called Pear-shaped, which was not the true Pear-shaped. Mr. Gilbert, gardener to the Marquis of Exeter, sent a dish of Figs grown out of doors against a wall, which were very rich in flavour, and highly commended by the Committee. Mr. Gilbert also sent a seedling Apple, which is a good early kitchen Apple.

Mr. Tillery, of Welbeck, sent a fine dish of Walburton Admirable Peach grown on a glass-covered wall. The fruit was large, and of excellent flavour, and received a special certificate. Mr. Coltown, gardener to James Blyth, Esq., Wolverhampton, sent a dish of noble specimens of Salway Peach. The flavour was good, and the Committee awarded a special certificate. Mr. Drewett, of Denbies, sent two brace of Cucumbers, two white and two black. They were very good, but not superior to others in cultivation.

Mr. Warner, of the Nurseries, Leicester, sent a Plum called the "Don Plum," which was evidently the old French variety the Prune d'Or. Mr. Forsyth, gardener to Baron Rothschild, Gunnersbury, sent three splendid Pines—two Smooth Cayenne, one of which weighed 8 lbs., and Charlotte Rothschild, which weighed 9 lbs. They were unanimously awarded a special certificate. Mr. Henry Clarke, gardener to Earl Cowper, Panshanger, sent a fruit of Prickly Cayenne, to which a special certificate was awarded.

Mr. William Paul sent an interesting collection of Apples and Pears, to which a special certificate was awarded. Mr. Rivers, of Sawbridgeworth, sent a very large collection of Apples, which also received a special certificate. Mr. W. Deans, of Jedburgh, sent fruit of a seedling Apple, which the Committee did not consider equal to many others in cultivation.

Mr. Melvillo, of Dalmeny Park, sent a seedling Grape, called Golden Prince, raised from the Lady Downe's crossed by Muscat Hamburgh; but the Committee did not entertain a favourable opinion of it. Mr. Samuel Horley, of Woolaton, Nottingham, sent specimens of his Conquerer Prize Celery, accompanied with a letter, from which the following is an extract:—

"I may remark, the Celery is of the quality usually grown in this locality for exhibition, and has been blanched by the usual process, that of first folding the plant to the necessary height in strong white paper, and then pilling up the earth in the usual manner. This keeps the leaves perfectly clean and free from blemish—points of great importance when growing Celery for exhibition; but it is only just to remark that Celery so blanched is never so sweet and delicate in flavour as when the earth is closely packed in direct contact with it, and the longer the Celery remains in the ground after it is blanched, the more delicate the flavour will be, the earth no doubt exercising the same purifying principle upon the plant as it does upon every other substance that is brought in contact with it.

"The seed from which the Celery sent was raised was sown on a slight bothed the first week in April, and has been grown on with the greatest luxuriance ever since. The cold weather in May somewhat retarded the growth. The soil in my garden is very rich in leaf mould and other vegetable matter, and weak manure water is freely used throughout the season but the solid manure is placed in the trench quite a foot below the plan as it is desirable the roots should not enter it until the plants begin to throw up their centre leaves, and then it enables them to do so with more than usual vigour. You will observe the breadth, smoothness, and solidity of the leaves of the specimens I send, the variety being in point of form, as nearly perfect as it is possible to obtain it."

Messrs. Downie, Laird, & Laing sent specimens of a Turnip-rooted Beet, which was deficient in colour, and much inferior to the Turnip-rooted Bassano. Thomas Laxton, Esq., of Stamford, brought a large collection of grafted Potatoes, accompanied with the following statement:—

"I grafted or attempted to graft forty-six tubers, but the remainder either failed to take before planting out, or have since either died or have not been perfectly united. Some of those sent will, perhaps, show this, but in other cases the old tubers seem to have been thoroughly exhausted by the grafted eye. After grafting them I plunged the tubers in cocoa refuse for a few weeks, until I saw whether the eyes had apparently become intimately attached to the tuber. They were afterwards planted in a spare corner and examined from time to time, and where any eye had been omitted to be removed from the tuber the shoot was extracted. The grafting operations were performed rather late in the season, when most of my early Potatoes had been planted. The sets were not earthed-up, and appear to have been attacked either by grubs or slugs."

Messrs. Cuthush & Son, of Highgate, sent a choice collection of Onions, which received a first-class certificate, and Messrs. Barr and Sugden sent their extensive collection, which was shown at the previous meeting. A report of them will be found in another page.

Floral Committee.—Rev. J. Dix in the chair. The great feature of this meeting was the large and interesting collections of Fungi; the advantage of seeing these named and arranged as to their edible or poisonous qualities is very great. We can only regret that there is so short a space of time for examining them. The plant and floral departments were unusually well represented, the collections of cut Roses from Cheshunt and Waltham Cross were superb. Mr. Melville, Dalmeny Park, sent a basket of hybrid Pansies, Viola Intea crossed with the ordinary yellow Pansy; in their present state nothing could be said of them. From Messrs. E. G. Henderson, came Achyrocline Saundersii, a small white-leaved plant suitable for edgings; Cineraria acanthifolia; and a very pretty white Bouvardia jasminiflora.

Messrs. Veitch were awarded a special certificate for a valuable specimen of Masdevallia Veitchii; and first-class certificates for Anæctochilus ordiana (?), Anæctochilus Dawsonianus pictus, Tydæa Nero, with very dark red flowers; Rhododendron Lobbii, bright scarlet tubular flowers; Seaforthia Veitchii, and Miltonia Warscewiczii; also a special certificate for the group of plants, and a special certificate for the collection of Orchids. Messrs. Veitch also exhibited a new form of Palm, Veitchia Johannis, from the South Sea Islands; Lobelia Blue Gem, the darkest shade yet grown; Oncidium weltoni, &c.

Mr. Bull sent a fine collection of plants. First-class certificates were awarded to Dekenia nobilis, Martinezia caryotæfolia, Ptychosperma elegans, Ptychosperma Alexandræ, Thrinax havanensis, and Plectocomia elongata. These were all different forms of Palms, some of them, not well known, and it is considered necessary to bring this fine class of plants forward, as they have been seen by few and are most ornamental. Among Mr. Bull's other plants were Bignonia mirabilis, Ficus dealbata, Tritonia aurea cancellata, Chamærops arborea, probably a form of C. humilis, Albuca fastigiata elongata, Acanthoriza Warscewiczii, Ptychosperma regia, Afzelia magnifica, and Mesembryanthemum cordifolium variegatum. A special certificate was awarded the collection.

Messrs. Downie, Laird, & Laing sent seedling Dahlia Princess Matilda. From Mr. W. Paul came a fine collection of cut Roses grown out of doors, which for the time of year were remarkably fine; also a collection of cut zonal Pelargoniums. A special certificate was awarded. Messrs. Cuthush sent Centaurea nivalis, and Mr. Woodward, Stoke, near Coventry, a seedling Fuchsia not equal to many sorts. Mr. G. Archer, Wellingborough, was awarded a special certificate for a fine collection of cut Conifers with their cones.

Mr. Turner, Slough, exhibited a white seedling zonal Pelargonium, The Bride; an Ivy-leaved seedling Compactum, with very broad white margin—first-class certificate; and Tropæolum Ochroleucum, one of

the most useful bedding plants yet raised. The foliage is bright yellow, the plant producing but few flowers. It is of a dwarf and compact habit, and will be found generally useful for decorative purposes. Mr. Turner sent also a small collection of Tricolor zonal Pelargoniums in great perfection, which were awarded a special certificate; also three stands of superb Dahlias, for which a similar award was made. Mr. Cliffe, gardener to Lord Egerton of Tatton, sent a fine specimen of Hippeastrum reticulatum, which was awarded a special certificate for good culture. From Mr. E. G. Bland, Richmond Hill, came four seedling zonal Pelargoniums of no merit, also a collection of cut zonal Pelargoniums. Etna was considered a fine and promising variety. Mr. Green, gardener to W. Wilson Saunders, Esq., exhibited a very interesting collection of plants, among them a very pretty flowering bulb, Bessera miniata—a special certificate was awarded. Messrs. Paul & Son, Cheshunt, brought a most beautiful seedling Cupressus called C. Lawsoniana pendula alba, for which a first-class certificate was given. This is an extremely handsome plant, and will be in great request. Messrs. Paul sent five boxes of magnificent Roses, which justly merited a special certificate.

Mr. James, Highgate, sent plants of his silver Tricolor zonal Pelargonium, Mrs. Col. Wilkinson. Messrs. Cripps, Tunbridge Wells, sent plants of Yucca (draconis)alba spica, Euonymus japonicus pulchellus (?) microphyllus, Cupressus Lawsoniana alba; Mr. Laxton, Stamford, a seedling Rose, Beauty of Stamford, of a promising character; Mr. G. Parker, Winkfield, seedling Dahlia Enchantress; Mr. Poynter, seedling Fuchsia Royalty, with deep yellow foliage; and Mr. Frost, Dropmore, fine specimens of cut Conifers with cones, for which a special certificate was given.

Messrs. Standish sent a small collection of plants, including Actinopteris radiata, Abies japonica, an Anthurium, Nerine Fothergillii, and very fine plants of Ficus macrophylla, having very ornamental foliage, and being of quick growth. The plant is an epiphyte, and grows 50 feet high. When it has exhausted the plant upon which it has grown, its long roots reach the ground, and form stout poles, by which the plant is supported, and then receives its nourishment.

Exhibition of Fungi.—For the prizes offered for the best collection of edible and poisonous Fungi there were five competitors, each showing collections of very considerable merit; and that which came from Mr. Worthington Smith contained, we believe, as many as seventy species. The first prize was awarded to Mr. English, of Epping, who had in his collection the following Agarics—viz., A. muscarius, excelsus, vaginatus, rachodes, melleus, personatus, nudus, cynthiformis, laccatus, alcalinus, primulus, squarrosus, tener, arvensis, fascicularis, and laccatus amethysteus, very beautiful; Coprinus comatus, Lactarius quietus, Russula rosacea, R. fragilis, Cantharellus cibarius, C. lutescens, Boletus luridus and subtomentosus, Hydnum repandum and erinaceus, Lycoperdon giganteum, Phallus impudicus, and many others. But what attracted attention more than anything else to this collection, was the beautifully preserved specimens of which Mr. English exhibited a number on invisible wire supports, and which are prepared by a process known only to himself, and that enables him to retain all the characters of the species unaltered.

The second prize went to Mr. Smith for the very extensive collection before alluded to, and which was accompanied by coloured drawings of a dozen species of Agaricus. One great merit of Mr. Smith's exhibition, as compared with the others, was that poisonous and edible species were to some extent distinguished as such, and this is a feature which, as Mr. Wilson Saunders justly remarked, it would be desirable to carry out more fully at subsequent exhibitions of Fungi. A knowledge of what are poisonous and what are perfectly safe species cannot be too widely spread abroad, for it is the want of that knowledge which prevents Fungi being used as articles of food to a much greater extent than they now are; at present they are regarded with distrust, both by rich and poor, for both are, as a rule, unable to distinguish between those which are hurtful and those which would form a grateful addition to many a dish. Mr. Smith sent among edible kinds Gomphidius glutinosus, Agaricus gambosus, Coprinus comatus, Agaricus rubescens, Boletus edulis, Agaricus Orcella, A. procerus, and A. rachodes, Lycoperdon giganteum, Marasmius Oreades, Clavaria rugosa, Fistulina hepatica, and Lactarius deliciosus; some, as Agaricus vaginatus, Paxillus involutus, and Boletus subtomentosus, which have the negative quality of being not poisonous; whilst of those which are poisonous he had a numerous collection, among which were Agaricus muscarius, Russula rosacea and fragilis, Boletus luridus, Lactarius vellarius, and many more, besides several marked suspicious or dangerous.

The third prize was awarded to G. W. Hoyle, Esq., of Reading, who had a good collection, and several of the specimens were excellent. From Mr. Edmonds, Chiswick House, came a basket containing a small collection most tastefully arranged; and Messrs. Carter & Co., were likewise exhibitors, having, along with others, a Giant Puff-ball, apparently in excellent condition for use. Further particulars respecting the exhibition of Fungi will be found in our report of the General Meeting, and we can only add, that we hope such exhibitions will be frequently repeated. They are instructive to those who attend them, beneficial to the Society, and promise by their results, direct and indirect, to be beneficial to the country at large.

General Meeting.—J. Bateman, Esq., F.R.S., in the chair. After the usual preliminary business had been gone through, the Rev. M. J. Berkeley said his observations would be principally confined to Fungi. Before touching upon these, however, he would just remark that an extremely pretty Epidendrum, sent by Dr. Rogers to the last meeting, proved to be Epidendrum glumaceum; also that though at one time Picea Pinsapo had been supposed to be merely a variety of P. cephalonica, the two are totally different, as evidenced by the cones sent by Mr. Frost, Mr. Archer, and others, those of cephalonica having secondary scales, whilst there is no trace of these in Pinsapo. This constituted a decided difference.

Mr. Berkeley next adverting to the exhibition of Fungi, said that last year, in his unavoidable absence, a brilliant lecture was given by Dr. Bull, of Hereford. That lecture he would not attempt to rival, but, instead, would read a letter he had received from Dr. Curtis, of North Carolina, shortly after the war between the southern and northern States of America had ended. Dr. Curtis stated that when the southern army were in straits they often lived on Fungi, and Dr. Curtis himself had lived on these for months together. Three prizes were offered for Fungi—viz., one by Mr. Wilson Saunders, one by Mrs. Lloyd Wynne, and one by Lady Dorothy Nevill. The first prize had been awarded to Mr. English, of Epping, not so much because it abounded in the same number of species that some of the other collections did, nor because the manner of arrangement was that suggested by Mr. Wilson Saunders, but chiefly on account of the mode of preservation employed. And here he (Mr. Berkeley) would remark that he had never seen any specimens of Fungi equal to those preserved by Mr. English, who had been employed for the British Museum, the South Kensington Museum, and had sent collections to Norwich, as well as to Dr. Balfour, at Edinburgh. The collection to which the second prize was awarded came from Mr. W. G. Smith, of North Grove West, Mildmay Park, who was known as a first-rate artist, and had supplied drawings of Fungi to the South Kensington Museum. His collection included a very rare species of Boletus with white spores, and many other species of great interest. The third prize was given to a collection from Mr. Hoyle, containing some particularly good specimens, but many of them were not named. Two other collections, both of considerable merit, were shown, the one by Mr. Edmonds, of Chiswick, the other by Messrs. Carter & Co.

Mr. Berkeley then noticed particularly a few of the species shown, the first being Boletus edulis. The merits of this, he said, were very little known in England. Dr. Badham, when at Tunbridge Wells, first taught the people there its value, and to this day it is sought after in the neighbourhood. It also abounds in Kew Gardens, whence some of the specimens before him came. When in Hanover lately he went to the markets, and saw abundance of the dried slices of this and other Fungi, which must grow there in the utmost profusion. It is difficult to distingnish it from other species when young, but when it grows older its stem becomes more reticulated, and is the only species which can be found with a reticulated stem. Boletus castaneus could not be mistaken for it, owing to the absence of reticulation, and by its being detestably bitter, whilst an unfailing character of Boletus luridus is its becoming dark blue when broken. Of the Agarics, Agaricus Orcella is one of the best, so is A. pranulus, often confounded with it, and A. nebularis is not very different. A. Oreades, or Champignon, no one could confound with others, being so much superior, and the gills being leathery and far apart. Agaricus virosus, of which specimens were shown to the meeting, though often eaten in London, is extremely dangerous. The question had often been asked of him, "How to distinguish edible from poisonous species?" and he confessed he was totally unable to answer it. Experience, a knowledge of the species, was the only guide; and the same thing applied to other classes of plants as well as Fungi, for a person unacquainted with the difference might mistake the wild Celery for the Water Cress. All Fungi he believed were wholesome if preserved with salt and vinegar the latter seeming to neutralise the poisonous principle of Fungi. Mr. Berkeley then related that Dr. Badham having sent Agaricus muscarius by mistake to a friend, and although only a small quantity had been eaten, it had the effect of producing intoxication, a purpose for which it is largely used in Kamtschatka along with Cranberry juice. In fact, it derived its specific name muscarius from its property of intoxicating flies. Mr. Berkeley then read Dr. Curtis's communication before alluded to, and which was as follows:—

"You have asked me to give you my 'experience with the eatable Mushrooms of America.' This will be most satisfactorily done, I presume, in pretty much the same style in which I would narrate it to you at your fireside. My experience runs back only about twelve or fifteen years. You may remember that, previous to this period, I expressed a fear of these edibles, as I had grown up with the common prejudices against them entertained by most people in this country. Having occasionally read of fearful accidents from their use, and there being abundance of other and wholesome food obtainable, I felt no inclination to run any risk in needlessly enlarging my bill of fare. Thus I had passed middle life without having once even tasted a Mushroom.

"But as under your guidance and assistance my knowledge of Fungi increased, a confidence in my ability to discriminate species grew up with it, and a curiosity to test the qualities of these much-lauded articles got the better of timidity; and now, I suppose, I can safely say that I have eaten a greater variety of Mushrooms than anyone on the American continent. I have even introduced several species before untried and unknown. From the beginning of my experiments, however, I have exercised great caution, even with species long recognised as safe and wholesome. In every case I began with only a single mouthful. No ill effect following, I made a second essay upon two or three mouthfuls, and so on gradually, until I made a full meal of them. Fortunately, I have never blundered upon any kind that was mischievous, although I have

eaten freely of forty species. This is due, perhaps, to my general acquaintance with species which have been long used in Europe, and hence I have made no experiments upon new species which had not some affinity or analogy with them.

"For instance, Agaricus campestris and arvensis being wholesome, I did not doubt but that A. amygdalinus (a new species, closely allied to A. arvensis), might be safely attempted, and it has proved equally safe and palatable. Indeed, this may be regarded as the safest of all species for gathering, as it can be discriminated from all others, even by a child or a blind person. Its taste and odour are so very like those of Peach kernels or bitter Almonds, that almost invariably the resemblance is immediately mentioned by those who taste it crude for the first time. This flavour is lost by cooking, unless the Mushroom be underdone. When thoroughly cooked I cannot myself distinguish it from A. campestris. One or two persons have expressed the opinion that they can distinguish it, and that it is not quite so good. Others, again, are equally positive that it is better. In the crude state I deem it the most palatable of all Mushrooms, as it leaves a very grateful after-taste upon the palate, fully equal to that of Almonds. This is the thing I sent you some years ago for cultivation, but which failed to grow. I very much wish it might be propagated in England, so that we might ascertain whether it would undergo any change of qualities in a different soil and climate. I have for some time been entertaining the suspicion that such is the case with many of our species. Thus, in European books the Morel is described as possessing a peculiar flavour, that has given its name to the Morello Cherry. I can detect nothing of the sort in our Morel. You speak of A. cæsarens ('Introduction to Cryptogamic Botany') as being 'perhaps the most delicious of all Fungi.' This grows in great quantities in our Oak forests, and may be obtained by the cartload in its season; but to my taste, and that of all my family, it is the most unpalatable of all our Fungi, nor can I find many of our most passionate mycophagists who will avow that they like it. I have tried it in almost every possible mode of cookery, but without success. There is a disagreeable saline flavour that we cannot remove nor overlay.

"In the Tricholoma section, in which are several species long known as edible, I did not hesitate to experiment upon any that had the odour and taste of fresh flour. I began with A. frumentaceus, not learning from books whether it had been eaten in Europe. To this I subsequently added three new American species belonging to the same group. All are excellent when stewed, and are especially valuable for their appearance in late autumn, even during hard frosts, when other Agarics are mostly out of season.

"Again, there seemed such a similarity of texture and habit between A. cæspitosus (Lentinus, Berk.) and A. melleus, although the former belongs to Clitocybe, that the temptation to a trial of it was irresistible. As it is found here in enormous quantities, and a single cluster often contains fifty to a hundred stems, it might well be deemed a valuable species in a time of scarcity. It would not be highly esteemed where other and better sorts can be had; but it is generally preferred to A. melleus. I have found this species very suitable for drying for winter use.

"Among Boleti I ventured, in ignorance if it had ever been eaten, to try B. collinitus, on account of its close relationship with B. flavidus. I am not particularly fond of Boleti, but this species has been pronounced delicious by some to whom I have sent it.

"So among the Polypores, I had no fear of harm from the use of a new American species (P. poripes, Fr.), on account of its relation to P. ovinus, of its texture, and its flavour. The taste of the crude specimen is like that of the best Chestnuts or Filberts. It has been compared even with the Cocoa Nut, and is certainly of very agreeable flavour. It does not, however, make a superior dish for the table, being rather too dry, but it is innocent and probably nutritious.

"Of the Merisma group of Polypores, having already tried P. frondosus, confluens, and sulphureus, I ventured, after some hesitation, and with more than usual caution, to test the virtues of a new American species (P. Berkeleyi, Fr.), notwithstanding the intense pungency of the raw material, which bites as fiercely as Lactarius piperatus. When young, and before the pores are visible, the substance is quite crisp and brittle, and in this state I have eaten it with impunity and with satisfaction, its pungency being all dissipated by stewing. I do not, however, deem it comparable with P. confluens, which is rather a favourite with me, as it is with some others to whom I have introduced it. P. sulphureus is just tolerable; safe, but not to be coveted when one can get better. When I say safe, I mean not poisonous. I cannot recommend it as a diet for weak stomachs, which should be said of some other Fungi of similar texture. I am here reminded of an experience I had three or four years ago with this species, which would have greatly alarmed me had it happened at an early date in my experiments, and which would, probably, have deterred anyone unused to this kind of diet from ever indulging in it again. I had a sumptuous dish of it on my supper-table, of which most of my family, as well as a guest passing the night with us, partook very freely. During the night I became exceedingly sick, and was not relieved until depleted of my supper. My first thought on the accession of the illness was of Polyporus sulphureus; but as I remembered that inflammation was one of the symptoms of Fungus-poisoning, and I could detect no indications of this in my case, I soon dismissed the rising fear, did not send for a doctor, nor take any remedy. Others, who had partaken of the fungus more freely than myself, were not at all affected; and I presume my sickness was no more induced by the Polypore than by the bread and butter I had eaten. And yet, had I alone partaken of the dish, or had one or two others been affected in like manner, doubtless the night attack would have been very confidently attributed by some to the Mushroom; or had this been my first trial of that article, possibly I might ever after have regarded it with suspicion. I learned a few days afterwards from one of our physicians, that this kind of sickness was then somewhat prevalent in the community, and could be attributed to no known cause. For the credit of this species, therefore, we were fortunately able to distinguish the *post hoc* from the *propter hoc*.

"There are families in America that for generations have freely and annually eaten Mushrooms, preserving a habit brought from Europe by their ancestors. In no case have I heard of an accident among them. I have known no instance of Mushroom-poisoning in this country, except where the victims rashly ventured upon the experiment without knowing one species from another. Among the families above mentioned, I have not met with any whose knowledge of Mushrooms extended beyond the common species (A. campestris) called Pink Gill in this country. Several such families live near me, but not one of them was aware, until I informed them, that there are other edible kinds. Everything but the Pink Gill, which had the form of a Mushroom, was to them a Toadstool and poisonous. When I first sent my son with a fine basket of Imperials (A. cæsareus), to an intelligent physician, who was extravagantly fond of the common Mushroom, the lad was greeted with the indignant exclamation, 'Boy, I wouldn't eat one of those things to save your father's head!' When told that they were eaten at my table, he accepted them, ate them, and has eaten many a one since, with all safety and with no little relish. Since that time our mycophagists eat whatever I send them without fear or suspicion.

"I have interested myself to extend the knowledge of these things among the lovers of Mushrooms, and also their use among those who have not before tried them. In the latter work I am not always successful, on account of a strong prejudice against vegetables with such contemptible names, and an unconquerable fear of accidents. Yet, as in my own case, curiosity often conquers these errors. When away from home I have frequently obtained ready permission from a kind hostess to have cooked a dish of Mushrooms that I have found on her premises. It has rarely occurred in such cases that the dish, then tasted for the first time, was not declared to be delicious, or the best thing ever put in the mouth. This latter phrase was once used in reference to so indifferent an article as A. saligneus. Indeed, I have found several persons who class this among the most palatable species. To such persons a dish of fresh Mushrooms need seldom be wanting, as this one can be had every month of the year in this latitude. I am induced to believe that the quality of this species varies with the kind of wood it grows from, and that it is better flavoured when gathered from the Mulberry, and especially from the Hickory, than when taken from most other trees. Its fitness for the table seems also to depend much upon the rapidity of its growth; those which grow slowly, as is the case with some of our garden vegetables, being of tougher texture and of less delicate flavour. A warm sun after heavy rains brings them out in greatest perfection.

"I have several times been asked by persons eating Mushrooms for the first time, whether these things belong to the vegetable or animal kingdom. There is certainly a very noticeable resemblance in the flavour of some of them to that of flesh, fish, or mollusc, so that the question, as founded merely on taste, is not an unnatural one. But I was much struck with its propriety when reading an article in 'Fraser's Magazine' a few years since, written by the late Mr. Broderip, who therein says that Mushrooms contain osmazome. If this be so, it accounts both for their flavour and for their value as food. Of this latter quality I had become so well convinced that, during our late war, I sometimes averred, and I doubt if there was much, if any, exaggeration in the assertion, that in some parts of the country I could maintain a regiment of soldiers five months of the year upon Mushrooms alone.

"This leads to a remark, which should not be overlooked, upon the great abundance of eatable Mushrooms in the United States. I think it is Dr. Badham who boasts of their unusual number in Great Britain, stating that there are thirty edible species in that kingdom. I cannot help thinking that this is an under-estimate. But if the doctor is correct, there is no comparison between the number in your country and this. I have collected and eaten forty species found within two miles of my house. There are some others within this limit which I have not yet eaten. In the catalogue of the plants of North Carolina, you will notice that I have indicated one hundred and eleven (111), species of edible Fungi known to inhabit this State. I have no doubt there are forty or fifty more, as the alpine portion of the State, which is very extensive and varied, has been very little explored in search of Fungi.

"In October, 1866, while on the Cumberland Mountains in Tennessee, a plateau less than 10.0 feet above the valleys below, although with little leisure for examination during the two days spent there, I counted eighteen species of edible Fungi. Of the four or five which I collected there for the table, all who partook of them, none of whom had before eaten Mushrooms, declared them most emphatically delicious. On my return homeward, while stopping for a few hours at a station in Virginia, I gathered eight good species within a few hundred yards of the depôt. And so it seems to be throughout the country. Hill and plain, mountain and valley, woods, fields, and pastures, swarm with a profusion of good nutritious Fungi, which are allowed to decay where they spring up, because people do not know how, or are afraid, to use them. By those of us who know their use their value was appreciated as never before during our late war, when other food, especially meat, was scarce and dear. Then such persons as I have heard express a preference for Mushrooms over meat had generally no need to lack grateful food, as it was easily had for the gathering, and within easy distance of their homes if living in the country. Such was not always the case, however. I remember on one occasion during that gloomy period, when there had been a protracted drought, and fleshy Fungi were to be found only in damp shaded woods, and but few even there, I was unable to find enough of any one species for a meal; so, gathering of every kind, I brought home thirteen different kinds, had them all cooked together in one grand pot-pourri, and made an excellent supper. Among these was the Chantarelle, upon which I would say a few words in confirmation of what I have already said upon the varying qualities of Mushrooms in different regions and localities. You have somewhere written of this Mushroom as being so highly-esteemed a delicacy, that it is much sought for when a dinner of state is given in London. Can this be because it is a rarity? (for nothing common and easily obtained is deemed a delicacy, I believe), or because you have it of finer flavour in England? Here, where it abounds, no one seems to care at all for it, and some would forego Mushrooms entirely rather than eat this. It certainly varies much in quality, as I have occasionally found it quite palatable, and again, though cooked in the same mode, very indifferent. I have been unable to ascertain whether this difference is due to locality, exposure, shade, soil, moisture, or temperature. That soil has much to do with the flavour of some species of Mushrooms I am well convinced. In a parcel of Pink Gills I have sometimes found one or two specimens, though perfectly sound, of such unpleasant odour and taste as would spoil a whole dish. So also with the Snowball (A. arvensis), of which I annually find a few beautiful specimens growing near my residence, upon a grassy turf which covers a pile of trash made up of decomposed sticks, leaves, and scrapings from the adjoining soil—their taste and odour is perfectly detestable. I had one specimen cooked, but no amount of seasoning could abate the offensiveness of the odious thing; yet within a hundred yards of these I gather specimens of the identical species, which are of fine flavour, equal to that of the best Mushrooms. As I have before intimated the varying flavour of Mushrooms growing on different kinds of wood, so here, I sup-

pose, the unpleasant qualities of some specimens of these two well-known and favourite species may be owing to something in the soil where they grow which they cannot assimilate, and which so renders a palatable and wholesome species totally unfit for the table. Whether such specimens, if eaten, would be poisonous or unwholesome I do not feel any temptation to prove. It is not probable that they will ever do any mischief, for it is incredible that any human being should so pervert his instincts as to swallow such a villainous concoction.

"Experience and observations like these would perhaps justify the inference that an innocent species may sometimes be deleterious, on account of its taking up some bad element from the soil. But as I have never known a case of poisoning in families that are well acquainted with the common Mushroom or Pink Gill, that gather the specimens for themselves, and have used this article of food annually for many generations, I cannot agree with a suggestion somewhere made by you, that perhaps all Mushrooms contain a poisonous element, but some of them in such small quantity as to have no appreciable effect. Now, had you seen the quantities of stewed Mushrooms swallowed at a single meal which I have seen thus devoured, and with no more harm than from the same amount of oyster or turtle soup, I think you would be forced to the conclusion that such an amount, even of poisonous infinitesimals, must have had some very unpleasant manifestations, or else be a very innocent diet.

"It is said that the sale of the Pink Gill (A. campestris), is forbidden in the Italian markets, because that species has often proved to be poisonous. May not this have been occasioned by ignorant and careless collectors or by worthless inspectors? To us in America, who use this species so freely and fearlessly, the Italian's curse, 'May he die of a Pratiola,' would have no more terror than 'May he die of aromatic pain.'

"Our best and standard Mushrooms are the Pink Gill (A. campestris); Snowball (A. arvensis); Peach Kernel (A. amygdalinus); Nut (A. procerus); French (A. prunulus); Morel (Morchella esculenta); Coral (Clavariæ); and Omelette (Lycoperdon giganteum). These are almost universally in high esteem. Yet tastes differ on these things as on fruits and vegetables; some putting one, some another, at the head of the list, though fond of all and ever ready to use either of them, as one who prefers a Peach may yet relish an Apple. There are some among us who regard A. procerus as fully equal to A. campestris, and I am almost of the same opinion. When broiled or fried it truly makes a luscious morsel. I must mention in this connection, that this species here bears the name of Nut Mushroom, from a quality that I do not find mentioned in the books which describe it. The stem when fresh and young has a sweet nutty flavour, very similar to that of the Hazel Nut. Is this the case with you? Its flavour is so agreeable that I am fond of chewing the fresh stems. From this peculiarity in connection with its moveable ring, its form, and colours, I deem it a perfectly safe species to recommend for collecting. We have no species likely to be mistaken for it, except A. rachodes, and I fully tested the innocence of this before commending the first to others. This has been suspected by some, but I have found it harmless. Though pretty well flavoured, it is not comparable with A. procerus, and the flesh is so thin and spongy that no one would choose it when those of more compact texture are to be had. A. excoriatus, of the same group, is a much preferable species.

"The Morel is one of my greatest favourites, but this is not found in quantity except in calcareous districts. A few days since (April 21st), I had a dozen for supper, the largest number I ever had at one time.

"The Lycoperdon giganteum is also a great favourite with me, as it is, indeed, with all my acquaintances who have tried it. It has not the high aroma of some others, but it has a delicacy of flavour that makes it superior to any omelette I have ever eaten. It seems, furthermore, to be so digestible as to adapt it to the most delicate stomachs. This is the Southdown of Mushrooms.

"In this latitude (about 36°) we can find good Mushrooms for the table during nine or ten months of the year. Including A. salignus, which some are quite fond of, we can have them in every month, as this species comes out during any warm spell in winter. A. campestris makes its appearance here as early as March, but not in full crop until September. Several excellent species of the Tricholoma group do not spring up until after frost sets in, and continue into December. Such is the case too with Boletus collinitus, which sometimes emerges from the earth frozen solid.

"These observations and experiences are confined chiefly to the Carolinas; though, I presume, from casual observations elsewhere, and from information derived from correspondents in other States, that making some allowance for difference of climate and length of seasons, what I have said is generally applicable to the whole country.—M. A. Curtis."

Mr. Wilson Saunders said, that seeing the interest excited in the exhibition of Fungi, he intended offering his prize another year. He wanted to try and teach people which of them are edible, which not so, but he would in future require the edible to be placed on one side, and those not known to be so on the other, not mixed together as at present. He would also require the names of the edible kinds to be given. He was convinced that the country was losing a great deal of good wholesome food from want of a knowledge of Fungi, of which numerous species are known to be safe; he was anxious that people should arrive at that knowledge, and considered exhibitions of the different species one of the best means to the end.

Mr. Bateman congratulated the Fellows on the success of the exhibition, and made some remarks on Truffle-hunting in the south of France, and on Fungi generally, while some of these, which had been cooked, were handed round, urging the Fellows to partake without fear, as the Council had set the example. He then produced some Mangos, which he had purchased in Covent Garden Market, thus partly fulfilling a prophecy of Sir Joseph Banks, that Mangos and Mangosteens would be sold in Covent Garden. This was the first time he had seen Mangos there; they came from Madeira, but the fruit had been ripened both at Chatsworth, and many years previously at Earl Powis's. After referring to the Cape Gooseberry previously noticed, he produced some Blackberries, which he was told were excellent in dumplings along with Berberries. Blackberries were appreciated both by rich and poor in North Staffordshire, and Blackberry jam had been found so effective in cases of fever in Bethnal Green, that a clergyman there had once advertised for them. After mentioning Hippeastrum reticulatum as being a beautiful free-flowering plant, known near Liverpool under the incorrect name of Bertolonia marmorata, likewise Bessera miniata, as being one of the charming plants he ever saw, Mr. Bateman said it was with painful feelings he looked at that bank of Orchids on his right, for it reminded of the removal from among us of Mr. James Veitch, the most energetic man the horticulture of this or any other country had ever known. In the beautiful Masdevallia that bears his name, there was an Orchid that would commemorate him as long as Orchids were cultivated. In Mr. Robert Thompson, too, they had lost one of the last of the old horticulturists, and one who had been indefatigable in his labours in connection with fruits.

The proceedings then concluded by the Chairman stating that the next meeting would be held on the 19th inst., when prizes would be offered for out-door Grapes.

The attendance at this meeting was larger than at any we remember, the Council-room being completely filled, as well as a portion of the adjoining colonnade.

REPORT ON ONIONS.

EXHIBITED BY MESSRS. BARR & SUGDEN, BEFORE THE FRUIT COMMITTEE OF THE ROYAL HORTICULTURAL SOCIETY.

Oblong or Pyriform Onions.—To this section belongs the Onion sold by the grocers under the various names of Spanish, Portugal, and Oporto Onion. The varieties cultivated in this country which most nearly approximate to the imported Onion are James's Keeping and Pear-shaped; they possess all the outward characteristics of this Onion, and, cultivated in the ordinary way, attain about the same size. There is not, of course, the beautiful clear skin on these Onions that there is on the imported ones, but there is no doubt this is the result of climate. The Giant Madeira attains a greater size. Some were grown within a few feet of the Oporto Onion, and they attained fully twice the size of the Oporto variety; they do not appear, however, to keep so well, as they are beginning already to grow. The group of Onions, Nos. 81 and 73, will show the relative sizes of these two Onions when grown in this country without any extra culture. Oxhorn belongs to this division of Onions, likewise Brown Globe and White Globe; the two latter varieties seem to be sold under the name of James's Keeping. This will be seen in two groups, No. 20, the one the White Globe, the other the Brown Globe. There are two samples also of Globe Onion, No. 85A and 85B, which were received from two London wholesale houses. The stock seems reverting to the flat form, which would bear out Mr. Thompson's suggestion that this Onion originated in the Blood Red. The Bedfordshire Champion Onion sent out by Messrs. Hurst & Son as a very superior new variety appears a very bad stock of James's Keeping and Brown Globe. Those who contributed specimens of the Oporto Onion, and also of other varieties of Onions for comparison, and whose names are attached to each group, are the following:—

Mr. Parsons, Daneshury.
Mr. John Standish, Ascot.
Mr. Rogers, Berryhill.
Mr. Dancer, Chiswick.
Mr. Bousie, Quantock Lodge.
Mr. Penfold, West Moulsey.
Mr. Goldsmith, Poleseden Lacey.
Mr. Simpson, Stoke Farm.
Mr. Burton, Heathfield.
Mr. Luckhurst, Egerton House, Hawkhurst.
Mr. Earley, Digswell.
Mr. Thos. Record, Lillesden.
Mr. Horley, Toddington.
Rev. W. F. Radclyffe, Okeford Fitzpaine.
Stuart & Mein, Kelso.
Royal Horticultural Gardens, Chiswick.
Mr. Gilbert, Burghley.
Mr. Stewart, Nuneham Park.
Mr. Rutland, Bentley Priory.
Mr. Lidgard, Albion Road, Hammersmith.

It will be observed with reference to the Oporto Onion that with a little attention we can in this country grow the Onions quite as large as they can in Oporto (for example those sent by Mr. Standish), and what, perhaps, is remarkable, in about half the time. Mr. Standish's Onions were not sown till the 1st of April, and they were pulled up in the middle of September, being five months and a half; whereas the Oporto Onion according to Mr. Crawford, British Consulate, Oporto, is eleven or twelve months in attaining its size. Whether the quality of the English-grown Onions is equal, the Committee must determine, as two Onions from the grocers' shops, two of Mr. Standish's Onion, and two of Nuneham Park, from Nuneham Park, are being cooked.

The next section of Onions which produce immense roots are the Giant Rocco, Santa Anne Giant Madeira, New Venetian Giant, Flat Giant Madeira, Red Flat Tripoli, and Red Sallon. Santa Anne Giant Madeira appears to be a variety of the Oporto Onion; the others seem all to belong to the Tripoli family. None of them promise to be good keepers, but under good cultivation they will attain an immense size. Of the

former and better-keeping classes of the pale red and brown-skinned Onions, there are Danvers' Yellow, St. Brienne, Pale Red Niort, Pale Red Flat Keeping, Common Pale Red, French Strasburg, Flesh-coloured Strasburg, Strasburg, Red Spanish, Yellow Flat Keeping, Very Large Yellow, Straw-colour. These have a strong family resemblance: most of them are medium-sized Onions, but some of them may be cultivated to a great size. The best are St. Brienne, Red Niort, and Danvers'. Of the lighter-skinned flat Onions, Very Large Yellow, Straw-coloured, Large Dutch Yellow, Sulphur, Sulphur Flat Keeping, White Spanish, and Nuneham, all resemble each other very much. The Nuneham Park is the thick-necked variety of the Spanish Onion, and is capable of being grown to the largest size. The variety of Spanish Onion mostly grown in Bedfordshire has a finer neck, and appears a finer-bred Onion than the Nuneham Park, though it does not appear to grow under superior treatment quite so large. Nos. 121 to 129 embrace the two classes of the White Spanish. Some seasons, when the Onion crop is a failure in this country, the Large Dutch Yellow is imported in large quantities to supplement the deficiency.

Red Onions.—These are variously sold as Blood Red, Dark Blood Red, Very Dark Blood Red, and Very Deep Blood Red. No. 66 is the largest in this section, and No. 70 the darkest. These Onions are reputed to be very strong in flavour, but probably the colour has suggested the idea.

White or Silver-skinned Onions.—These are sold under a great many names:—Very Early Silver-skinned, Early Silver-skinned, Very Early Paris Silver-skinned, Early Paris Silver-skinned, Large Early Paris Silver-skinned, Early Nocera Silver-skinned, Extra Early Nocera Silver-skinned, White Tripoli, White Valentia, Silver Keeping, and White Lisbon. The variation in the names seems greater than the variation of the bulbs. Some sorts may probably keep better than others, and some probably grow larger than others. The coarsest sort appears to be the Lisbon, and the true imported White Italian Tripoli, No. 61, the finest. This variety appears, however, somewhat difficult to procure genuine. Two samples had from two wholesale London houses, gave about a third of white, and these appear coarse. All the white Onions are mild in flavour. They are amongst the earliest to come into use, and for pickling are certainly very desirable both on account of colour and quality.

The *Two-bladed Onion* is a pretty little variety, much prized by many for pickling.

The *Potato Onion* is a large mild-flavoured variety, not usually produced from seed. No. 155 was received from Mr. Gilbert, of Burghley. No. 122 is the produce of seed. In Devonshire, where this Onion is extensively cultivated, they are in the habit of planting them on the shortest day, and lifting them on the longest.

The *Tree, or Bulb-bearing Onion*, sometimes called the Rocambole Onion, produces small bulbs on the stalk instead of flowers. These are greatly prized for pickling. It also forms roots under ground.

The Onions commencing at No. 48 to No. 131 are simply to be considered as a collection. Nos. 1 to 47, and Nos. 132 to 161 are more or less specimens of good cultivation, being contributions as already notified.

POMOLOGICAL GLEANINGS.

The Atlas Nut (Corylus algeriensis).—I enclose some leaves of this Nut, they are remarkable for their size and rugose nature. The sort was received from the south of France some years ago, under its Latin appellation, and was said to be from the Atlas. It is simply a good Nut, but from its enormous clusters, often from eight to twelve nuts in each, and its distinct robust habit, it is worthy of notice.—T. R.

[The leaves are immense and nearly quite round.—Eds.]

—— The Summer Beurré d'Aremberg Pear.—This most delicious Pear bears so profusely that it requires its clusters of fruit to be thinned to obtain fair-sized fruit; this should be done in July.—T. R.

—— A New Transparent Gage Plum.—A young seedling tree raised from this fine Plum, bore some fruit here for the first time this season. They were remarkable for their size and beauty, and for being a fortnight or more earlier than the original sort, which (September 25th), is not yet ripe. Colour of skin yellowish green, nearly covered with crimson blotches; flesh parting from the stone like an Orleans, and juicy and rich as its parent. No Plum can surpass it in this respect. The most curious feature in the seedling is, that instead of having very vigorous, smooth, straggling shoots like its parent, its shoots are downy, and the habit of the tree compact. It will be some few years before this sort can be distributed, as the tree is but three years old, and had but one or two young shoots on it fit for propagation. I am induced to mention this seedling Plum, as it may encourage others to raise seedlings from our choice fruits. It is, however, curious to observe, that two other seedling Plums of the same age and raised from the same sort have produced small purple Plums of no value. —T. R.

—— The Bryanston Gage Plum.—This sort has been in cultivation some thirty or forty years, yet is but little known. It is now (the end of September), fully ripe, and very rich and good it is. The habit of the tree much resembles that of Reine Claude de Bavay, and its fruit greatly resembles it, but is not quite so large. Its colour is a light greenish yellow, and its skin is covered with a delicate white bloom; its flesh is transparent and remarkably juicy and refreshing. I presume that this variety of the Gage race of Plums is of English origin, but I forget its history.—T. R.

LAXTON'S SUPREME PEA.

Having read the correspondence under the above heading, I think it right to state the result of my trial of Laxton's Supreme Pea. I, like many others probably, was induced from the wonderful drawing and description in the catalogue sent out by Messrs. Carter & Co., to give it a trial, and the result was, as regards its growth, quite the reverse of that described by "C. C. E." With me the haulm did not exceed in height 1½ foot; the pods were small and contained from three to four peas of small size; it was sown at the same time as and adjoining a row of Laxton's Prolific, which latter attained the height of 4½ feet, and cropped abundantly, with large pods mostly containing eight or nine peas, and this is, I consider, after three years' trial a first-class Pea.

As regards the price charged for Laxton's Supreme Pea, I should not complain had it at all answered to the description given, but I certainly feel it an imposition to be charged 3*s.* 6*d.* per half pint for what has proved with me a very inferior article, and the only conclusion I can come to is, that I have been supplied with the wrong seed, although I obtained it from the firm of Carter & Co., in a sealed packet. I shall certainly in future disregard the glowing descriptions of novelties set forth in catalogues.—A Constant Reader.

I can fully confirm the remarks made by "C. C. E.," respecting Laxton's Supreme Pea, and can also find several others in this immediate neighbourhood who, like myself, purchased it at 3*s.* 6*d.* per sealed packet, thinking that thereby we should at least obtain a Pea of dwarfish habit; but instead of such we have been annoyed to find Peas rising to the height of 7 and 8 feet, in positions not at all suited to such rampant growths.—An Old Subscriber, *Newark-on-Trent*.

If your correspondent "C. C. E." will be good enough to turn to the report of the Fruit Committee of the Royal Horticultural Society dated June 29, 1868, he will find that at that comparatively early period Laxton's Supreme Pea had arrived at maturity in the gardens, and is specially noticed as "a grand Pea, with very long well-filled curved pods." Our own trials had been even earlier. It was with this independent testimony, in addition to our own observations, that we joined in the effort to introduce the Supreme Pea to our friends and the public, and the description we gave was in perfect good faith. The Pea with us and at Chiswick grew compact, under 4 feet, and early; and the only mistake made was, that the peculiar character of the early summer of 1868 was not, perhaps, taken into consideration as it should have been. The extremely hot forcing weather tended, no doubt, to check the growth and hasten the ripening of the crop.

We confess that this summer we have seen the Pea much taller on certain soils than we anticipated, and our own trials did not yield Peas so early as did those of 1868; but we still hold the Pea in the very highest admiration, and shall confidently recommend it to all who deal with us as one of the handsomest and most valuable varieties for both quantity and quality that has ever been sent out. We have seen it in many places with branches quite as good as that depicted on the plate. We trust your correspondent will see that we have

reason for saying we are not to blame, and that another trial next summer will lead him to think as we do of the Pea.—HURST & SON, 6, *Leadenhall Street.*

"C. C. E." positively surprises us when stating that Laxton's Supreme Pea "in no way resembled its picture and description, save in its pods." Did "C. C. E." satisfy himself, by examining every pod, of the exact maximum of peas in a pod? Did he actually measure the haulm himself and discover the length to be as he asserts? Lastly, will he acknowledge the fairness with which the Royal Horticultural Society's trials are conducted, and the honesty of our intentions when endorsing our own experience with the evidence of such trials?

Now, as to the price. "C. C. E.'s" ideas are so original, that whilst at one moment we realise the severity of his remarks, at another we are almost disposed to flatter ourselves with the belief that he treats us as horticultural philanthropists. For instance, he says, "it matters not to the grower whether they (the enterprising seedsmen) give £100 or 100 pence per bushel for the Peas;" and whilst acknowledging the great things we, with many others, have done for horticulture, he adds, "their (the seedsmen's), prices for stock seed is their affair, not the grower's (purchaser's), being purely a trade speculation, &c." The question, therefore, is best answered in "C. C. E.'s" admission, that it is "purely a trade speculation, founded on their own experience and acumen."—JAMES CARTER & Co.

[The last is an extract from a communication received from Messrs. Carter & Co., and here the controversy must close. By most growers of the Pea in question it is stated to be of average quality, but it is not a dwarf variety, except on poor soils. The preceding notes and many others in our possession, signed "KITCHEN GARDENER," "A VICTIM," &c., are from practical men, and they all condemn the exaggerated statements.—EDS.]

GRAFTING TRICOLOR PELARGONIUMS.

MOST gardeners are aware of the fact that these beautiful plants are very slow growers, and, consequently, they find a great difficulty in propagating a sufficient number to meet their requirements. Now, if any of your readers have this difficulty and wish to overcome it, I advise them to follow my plan, which I shall describe as briefly as possible.

In March select some old plants of Rubens, Tom Thumb, or Punch Pelargoniums, which are strong growers, place them in a brisk heat so as to drive the sap strongly up, then head them down to about 2 inches, and graft Italia Unita, Sophia Dumaresque, or Lady Cullum upon the stocks. This must be done neatly and expertly to insure success.

In about three weeks the scion and stock will be found adhering to each other, and will soon be throwing out buds in all directions, and the plants will be ready to plant out at the same time as the rest of bedding plants, if gradually hardened off.

It is astonishing how quickly Pelargoniums grow when treated in this manner. This spring, for instance, I had one plant, a very small one, of Italia Unita, from which I took a graft, and the grafted plant furnished thrice as many cuttings, and made a finer plant too than the plant on its own roots. I am aware that grafting these plants is no novelty, but where cuttings are wanted the practice is well worth carrying out. I did not observe that grafting had much effect on the colours, but it certainly induced a vigorous constitution in the graft—a great desideratum where a specimen plant is required for exhibition, or for general conservatory decoration.—JOHN BOWLEY.

MARÉCHAL NIEL ROSE.

IT may be useful to Rose-growers to know that Maréchal Niel succeeds admirably on Jane Gray. I had a tree of the latter Rose against a south wall, which, even here in Devonshire, would not flower; in despair I moved it into a corner of the kitchen garden, and budded it on one stem with Maréchal Niel, and now it has fine flower buds and blooms. All its shoots are exceedingly vigorous, though against a north wall.—G. E. E.

NOTES AND GLEANINGS.

ON a reference to our advertising columns it will be seen that a second edition of the Rev. J. Fountaine's pamphlet, 'THE NEW METHOD OF GROWING FRUIT," is now published, and may be had at our office.

—— THE RIGHT HON. GEORGE PATTON, Lord Justice Clerk, and Lord President of the Second Division of the Court of Session in Scotland, under the title of Lord Glenalmond, whose melancholy death occurred on the 20th ult., was third son of the late James Patton, Esq., of Glenalmond, Sheriff Clerk of Perthshire, by Anne, his wife, daughter of Thomas Marshall, Esq. He was born in 1803, and after following his studies at the Perth Academy and the University of Edinburgh, finished his education at Trinity College, Cambridge. Adopting the profession of the law, he became a Scotch Advocate in 1828, and was Solicitor-General for Scotland in 1859. In June, 1866, he was returned to Parliament by Bridgwater; but, accepting shortly after the appointment of Lord Advocate, he had to vacate his seat, and was defeated by Mr. Vanderbyl at the election which ensued. In 1867 he succeeded Mr. Inglis (Lord Glencorse) as Lord Justice Clerk, and was sworn of the Privy Council. He married, in 1857, Margaret, daughter of the late Lieutenant-General Bethune, of Blebo, in the county of Fife.

Mr. Patton was fond of gardening in all its departments, but especially of arboriculture. He aided in founding the Oregon Botanic Association, and one of the Conifers resulting from its researches was named in his honour Abies Pattoniana. It is the Great Californian Spruce, and well merits to be more cultivated. The following is extracted from Gordon's Supplement to his "Pinetum:"—"This Fir grows under favourable circumstances to an immense size in the Oregon country, where not unfrequently trees are seen from 30 to 40 feet in circumference, 4 feet from the ground, and towering upwards some 250 feet, or more, with 100 feet of the trunk entirely free from branches. The timber is excellent, splits freely, and quite straight in the grain.

"Dr. Newberry, in his report on the Exploratory Expedition and Surveys from the Mississippi River to the Pacific Ocean, describes this Fir under the name of Abies Williamsonii; and more recently, Mr. Bridges, a collector in California, has been disposing of seeds of a very different kind under the same name; Dr. Newberry's sort being identical with Abies Pattoni (the Giant Fir of California), while that sold by Bridges under the name of Abies Williamsonii is the same as Abies Mertensiana (the Hemlock Spruce of California).

"The Abies Pattoni occupies the most elevated parts of the Sierra Nevada, and seldom descends lower down than 100 yards from the line of perpetual snow, where in moist situations it forms a tree from 100 to 130 feet high, with a trunk sometimes 3 feet in diameter. Its branches spread out horizontally from the main stem, but become drooping towards the extremities, and with the branchlets thickly set round with solitary leaves about two-thirds of an inch long, grass green above, and pale green beneath, with those towards the points of the branchlets spreading, and silvery white below. The cones are about 2 inches long, and 1 inch in diameter, in the widest part; when young, dark purple, but when old, pale brown. Male flowers, or catkins, two-eighths of an inch long, and of a violet colour. The timber is of a reddish colour, close, and fine-grained, and remarkable for its strength and durability, and as an ornamental tree for parks or pleasure grounds, or for general planting, no tree can be more recommendable; and, judging from the soil and situation in which it grows, it may be considered the hardiest of all the Californian kinds.

"Mr. William Lobb found it in abundance, on the highest peaks of the Sierra Nevada, near the head waters of the north tributary of Feather River, and more to the south, toward Lake Bigler, forming immense trees, in habit of growth and general appearance much resembling the Deodar, but being more thickly branched, and densely clothed with foliage; by far the handsomest tree."

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHERE Box-edgings require relaying, or walks require gravelling, let the work be done at once, for when the season is further advanced frosts interfere, and other pressing work, as nailing, will require attention. Continue to trench every spare piece of ground, either to receive crops or to benefit by the action of frost and air. It is now high time to check *Broccoli* that is growing luxuriantly, by laying the plants down. Constant attention is necessary to secure from slugs the plantations of *Cabbages*, and of *Cauliflowers* under hand-lights, frames, or in other places of shelter; dust the ground between the plants every second day with soot and quicklime, and make good the blanks from the seed beds. The same directions apply to the winter *Lettuce*. Take care to secure a good supply of *Endive*

for winter use. The *Celery* leaf-miner is reported to be very prevalent this autumn; the best remedy, perhaps, is picking off the affected leaves and burning them. Where there is room to spare in the Mushroom house, a little *Sea-kale*, if wanted, may be forced. The roots should be placed on a slight bed of warm dung, filling up the spaces between them with old tan, or with the mixed soil and manure from an old Mushroom bed, giving a good watering to wash it in amongst the roots. The bottom heat should not exceed 70°, as too much heat is not favourable to strong growth. Take advantage of wet days for making fresh *Mushroom* beds, and clearing out those which are spent; also collect and prepare droppings for forming fresh beds, by spreading them in a shed and turning them every day until they are sufficiently dried to prevent excessive fermentation after putting up. Carefully examine *Onion* stores, and remove all the bulbs in which there are any symptoms of decay.

FRUIT GARDEN.

The fine weather which we have lately experienced has been very favourable to the ripening of late fruits. Continue, therefore, gathering both Apples and Pears, most varieties of which will now be ready. Nonpareil Apples should be amongst the last gathered, and the same may be said of Glou Morçeau, Beurré Rance, and Easter Beurré Pears. If Coe's Golden Drop Plums be carefully gathered, wrapped singly in thin paper, after remaining some days in a dry, airy room, and then packed in shallow boxes, they will keep a long time, and so will the Blue Impératrice and the Ickworth Impératrice, the latter being the preferable Plum. It cannot be too often repeated, that all choice fruit should be gathered when perfectly dry; and in storing, wherever an extensive surface of fruit is exposed, air must be admitted freely, for at this period exhalations are most abundantly given out, and more especially by the early varieties on their becoming fit for use. These, in fact, ought not to be in the same apartment with the more valuable late-keeping sorts. Look frequently over the fruit room, and remove at once any fruit that appears to be unsound.

FLOWER GARDEN.

Chrysanthemums are now everywhere occupying attention. Let them be tied out, so as to display their blossoms to the best advantage. Protecting materials must soon be prepared for such plants as require to be covered up in the winter. When dry fern can be had, it answers the purpose perfectly. Choice sorts of Hollyhocks may soon be taken up, potted, and wintered in a cool house. They will be exceedingly useful for furnishing cuttings, and these, if put in early in spring, will make excellent plants for next season. Be careful to secure against wind plants which have been transplanted, especially those which are of large size. All such should never be left until they are properly staked, or otherwise made fast; it frequently happens that the roots are injured through the tops being rocked about. Deeply trench and ridge-up ground intended to be planted with Dahlias and Hollyhocks next season, so as to expose it as much as possible to the weather, putting in plenty of rotten manure, especially where the Hollyhocks are to be planted, for these require a rich, deep soil. Alterations of grounds, and the planting of evergreens, should now be carried on with dispatch; but never attempt planting where the soil is not in good condition. The drier soil is when placed round the roots of newly-planted shrubs, provided they are judiciously watered-in, the sooner they emit fresh roots. Mulching is, however, requisite to keep out frost, and earlier in the season to prevent evaporation. As tree leaves are always in request, either as a fermenting material, or for leaf soil, they should be carefully collected. If they are required only as manure, they may be stored in any by-place and left to rot; but if, as is generally the case, they are in demand as a cheap mode of furnishing bottom heat to Pines, as well as for forcing different kinds of vegetables, care should be taken to keep them dry. For this purpose they should be stacked-up in some back place, or behind the garden walls, where access to them can always be had; and after allowing time for them to settle, put on a coat of thatch to effectually secure them from rain. By these means they will remain fit for use for a twelvemonth.

GREENHOUSE AND CONSERVATORY.

In most places Chrysanthemums will soon be the chief features of attraction, and where these are largely grown, which they should be wherever there is a demand for flowers late in autumn, they make a fine display, and are worth every necessary attention to preserve them in beauty as long as possible. They are very impatient of a close, rather moist atmosphere, and if the house contains plants requiring such, the Chrysanthemums should, as far as practicable, be placed in the coolest part, where air can be given freely at every favourable opportunity, for unless they can be freely exposed to air, their foliage will soon be attacked and disfigured by mildew, especially if the plants are bushy and well grown. See also that they are kept well watered at the root. Use fire heat only when absolutely necessary, either to prevent the temperature from falling too low, or to dry the atmosphere. If Pelargoniums, Cinerarias, and Calceolarias must be wintered in the same house with Heaths and other hardwooded plants, they should be kept as much as possible by themselves, as they will require a somewhat closer temperature than hardwooded plants; but where circumstances admit, these should occupy a house or pit by themselves. Cinerarias and Pelargoniums intended for late flowering will do very well in a cold pit if the weather should not prove unfavourable; but those intended for flowering early should be placed where fire heat can be used, so as to preserve the foliage from damp. Roses for early forcing must soon be pruned, and placed where they will at least be safe from heavy rains. When American and other shrubs are used for forcing, these should be taken up and potted without delay, placing them in a cold pit until they are wanted for forcing, or in a turf pit, where they can be protected from severe weather by straw mats, shutters, or other covering. Summer-flowering twiners, which usually become unsightly at this season, should be cut-back freely, as well as any others that will submit to this treatment.

COLD PITS.

The time has now arrived for putting in readiness straw shutters, or whatever else it may be intended to use for coverings. Straw shutters, if well made, are expensive in the first instance, but are considered by many to be the most efficient of all coverings in use, and taking into account the time they last, they are, perhaps, as cheap as any. Expose the stock in pits freely to air at every opportunity, so as to check growth and render the wood firm. Little water will be required at the roots, but look over the plants every few days, withholding water until it is absolutely necessary, and then giving a moderate soaking. Heaths and other plants subject to the attacks of mildew, must be closely watched, and sulphur applied the moment the enemy is perceived.—W. KEANE.

DOINGS OF THE LAST WEEK.

Gardens Invaded by Roots of Trees.—An old correspondent proposes using clay in another way, and we regret to say that we can hold out to him little hope of success. He has a neat little flower garden in an open spot, with every advantage of full sunshine, while gusts of wind are kept out by a wide belt of trees, of which Ash, Elm, and Lime form part. Lately, though he changes the soil of his beds frequently, they soon become a mass of tree roots, and the flowers cease to thrive. His soil is a loam, in all respects good but for the interloping roots. He has clay fit for bricks at a short distance, and he purposes taking out a trench 2 feet deep all round his little flower garden, and by means of boards making a wall at least 9 inches wide of rammed clay, hoping this will make the roots turn back. We have no faith in the efficacy of the clay wall however firm. The roots, if they cannot easily pass through it, will go beneath it, and rise into the good soil, or go over the top of it, and strike down. Though such surface-rooters may not like the clay much, we have seen Ash and Elm roots filling clay with rootlets as thickly as they could well be, and all the more when something like instinct indicated to them that there was rich feeding-ground beyond.

We recollect of a well in a garden being filled with Lime-tree roots instead of water, and such a mass that they resembled a cheese or a piece of wood in firmness, and yet the roots to find their way there must have first passed a macadamised road, gone under the house and outhouses, and through part of the garden to the well. Roots often become similarly matted in drain tiles, and then it is impossible for water to pass. The masses of rootlets become so wedged-in, that they can only be seen by breaking the tile.

We have no faith, therefore, in a wall of clay, however puddled and hammered, in keeping out roots. Many kitchen gardens and flower gardens, however, suffer constantly from the incursions of the roots of trees, which in the fine soil soon spread like a network throughout. The only effectual mode in a flower garden for giving the flowers justice, and yet pre-

serving the shelter and beauty of the neighbouring trees, is to take out the soil all round the flower garden to the depth of a least 3 feet, and build a wall of brick and cement to within a few inches of the surface. It would be easy to prevent the roots passing over it under the turf. Nothing else will keep them out, and no flowering plants will long thrive if roots of Elm, Ash, and other trees, fill the soil. Some time ago, we were surprised to notice a plantation of Raspberries becoming worse every year, notwithstanding manuring. On examination, we found the soil a network of Elm roots, and they must have travelled 50 yards to reach the fine garden soil. In kitchen gardens unenclosed, an open trench or ditch fresh turned out frequently would be as effectual as the wall in the flower garden. We can recollect of numbers of flower beds that will only give the satisfaction which their position should command when the roots of trees are rigidly excluded from them. It is of little use cutting the roots, and supplying fresh soil; in one season the bed will be interlaced with fibres. Next to having plants devoured by vermin, there are few things more discouraging than attempting to grow flowers in beds crowded with the fibres and roots of surface-rooting trees.

Rubbish Heaps.—These are rather unsightly objects in most gardens, and will always be so where time cannot be found to attend to them properly. By the rubbish heap, we mean a heap of all the refuse that comes from a garden, the spent earth from the potting bench, all weeds, except seed and root weeds, which are best disposed of by burning, all Cabbage stalks and leaves, Bean stalks that are not burned or charred, short grass and mowings from the lawn when these do not form parts of fermenting manure heaps, and which add more richness than is imagined to all manure or compost heaps of which they form part. The rubbish heap, when properly managed, will be the means of returning to the garden much of what was taken from it, and for many purposes is not inferior to half-decomposed stable manure. Its enriching properties will to a great extent depend on bringing the whole mass into a state of gentle fermentation, and having the fermenting material so covered that the fertilising properties are allowed to escape into the open air as little as possible. The more this is attended to during the season, the more effective will dressings from the rubbish heap be.

KITCHEN GARDEN.

Took up the last of the Onions, and trenched the ground so as to be ready for planting Cabbages. Stirred the soil among those planted. Coleworts, &c., are growing rapidly after the rains, and Cauliflowers, which were almost standing still, have done wonders after the sewage water and the rains. Took up another piece of Carrots, as we wanted the ground.

Celery.—We have lately noticed this at considerable length, yet it may be as well to note that we have this season a little of the Celery grub or caterpillar, which we have not had for a number of years. Though we have not much of it, it is worth looking after and destroying, as thus we shall be more apt to escape its attentions in a subsequent season. The grub itself is rarely seen without looking for it, as it houses itself between the two skins of the leaf, and feeds on the tissues inside. Its presence is easily perceived by parts of the foliage assuming a dead, blistered appearance. In each of those blistered parts a caterpillar either is or has been, and the longer it remains the larger will the blistered space be, as the whole of the interior will be eaten up, except the gossamer-like skins left. The grub seems to have no access to air, except what may pass through the epidermis of the leaf. Many years ago we used to wonder how the grub found its way into the leaf, as not the smallest opening could be observed by which it could enter. The grub is the larva of a small and pretty fly (*Tephritis onopordinis*), the body of which is not a quarter of an inch in length, and the wings when expanded not more than half an inch across. These deposit their eggs under the epidermis of the Celery leaf in June and onwards. The eggs soon hatch into grubs, and these eat as they grow, until, arriving at maturity, they make a way out for themselves, go into the ground, and remain in a dormant chrysalis state until the next summer, when they appear in the winged state, and do little or no harm, except depositing their eggs to furnish future generations.

Squeezing the blistered places so as to destroy the grub will be sufficient, but it is preferable to cut the blisters off, and burn them, as they look unsightly, and this will prevent the grub arriving at the chrysalis state. Strong scents, as tar, will help to keep the winged insect away. Ten years ago, or more, after being visited with the grub in the previous year, we run some tar cord over the beds, and we also found dusting the foliage slightly with soot good means of keeping the insect from depositing its eggs. This once done, and the young grub protected by the epidermis of the leaf, no application to the foliage of any powder or liquid that would not hurt the plant will have any effect on the grubs. To destroy them they must be squeezed in their feeding chambers, or removed with their blistered domiciles. We should bear in mind that each of these grubs that safely passes the winter, and becomes a fly in the following summer, may, by depositing its eggs, be the parent of numberless grubs to cause trouble in the future.

FRUIT GARDEN.

The chief work has been looking after Strawberry plants in pots, and cleaning the main plantations, which ought to have been done earlier, only other work was so pressing; but the sooner the Strawberries are cleared of runners, and mulched after their bearing is over, the better it will be for them. If the heavy rains continue, a few of the forward plants in pots will be laid on their sides, as it is possible for them to be too much washed for the early ripening of the buds.

Gathered Apples and Pears on fine sunny days as the fruit became fit, for in this fine, mild, moist weather what will stand had better remain a little longer. Where the growth of the trees of early kinds is too rampant root-pruning may be resorted to as soon as the fruit is gathered, doing it gently, so as not to interfere with the next season's crop. Where planting is to be done, the ground should be prepared as soon as possible. In all cases where early fruiting is an object it is well to make hillocks above the surface, so that the roots at planting shall be nearly on the surface level. These will soon go deep enough if left to themselves; but the trees may be strong enough and fruitful enough, with the roots running near the surface, if surface-mulchings be used every summer, and especially after the ground becomes warmed by the sun's rays. If we could do as we like, we would trouble ourselves little with tall trees in orchards, but would grow most fruit trees in private gardens in quarters of bushes or pyramids, where they would suffer but little in such storms of wind as we have had this season, which in some places scarcely left a fruit on the trees. Apples, &c., were a drug in the country markets in consequence, but good keeping sorts we expect to be scarce and high-priced. Removed second breastwood from trees, that the autumn sun might have more power on the buds. Lighted fires, especially during the day, in late vineries, and looked after any appearance of damped berries. Turned the linings of beds that have Melons and Cucumbers in them. Pruned freely the beds of Cucumbers in frames that have borne all the season, and we expect to obtain more fruit from them before the autumn becomes too cold. The linings of these beds had never been turned previously since they were made in spring. The keeping a mild heat, especially in the front of the beds, is partly owing to the dry summer, and partly to the rough spouting in front, which prevented rains and heavy dews on the glass from trickling into the beds in front.

ORNAMENTAL DEPARTMENT.

Notwithstanding the rain and all drawbacks, the flower garden is still very fair, partly, no doubt, owing to the mildness of the weather. The chief drawback is that the leaves from lofty Elms and other trees are falling, and are driven over the smooth-cut lawns, these leaves falling all the sooner owing to the battering they had from each other during the tempests. After one of these tempests the foliage on fine trees looked as parched and brown as if the leaves had suddenly, when quite green, been visited with from 5° to 10° of frost.

Nearly finished all our cuttings for bedding except Calceolarias, and these we shall let alone for two or three weeks if the weather remain mild, as we hope it will do, for by that time we shall be able to move other cuttings to give them room; and if we insert the Calceolarias earlier they root too soon, and become too crowded in the cutting bed before we can turn them out into earth pits in spring. We are quite satisfied if our Calceolarias root little or none until the new year. We generally allow about 1½ inch from cutting to cutting. The heavy rains on Friday night have made the Calceolarias duller than they have been all the summer, as so many flowers have fallen, but there are plenty of strong buds ready to open, and they will be gay for some time if the weather continue mild and sunny.

Among florists' flowers, *Auriculas* should now be under protection, as they suffer much from dashing rains, and continued wet is apt to bring on canker and other evils. At this period no place is better than not far from the glass, in a frame or pit,

and for a few weeks the pots will be better set on a firm bottom, as on a slate or tile, instead of being plunged. Before taking them under glass the bottom of the pot should be examined to see if the hole is all clear, for it frequently becomes choked up, and the plant is water-logged, which is ruinous to an Auricula. In such mild weather the sashes should be raised back and front night and day, so that the plants may have abundance of air, and be sheltered from rain. After a month or so they will pass more safely through the winter if the pots be plunged in rough coal ashes, as the plunging is alike a preservative against frost and dryness; and thus treated, unless in very bright winters, the plants will require little watering unt ilthe spring.

Polyanthuses require rather less trouble than Auriculas, and the finest are well worthy of the extra attention. Pinks and Carnations, if potted, should receive all the air possible, so as to keep them strong and sturdy. Wallflowers may be potted for winter flowering. Dahlias are still in their beauty, and besides securing, they need no attention, except when frost is apprehended, placing 3 or 4 inches of soil round the stems, to save the tubers. Dahlias generally keep better when not taken up until the frost has arrested all growth, but they should not remain in the ground long afterwards, as, not to speak of frost, the damp and rains lodging about the collars of the tubers are apt to rot and destroy the incipient buds, even though the tubers to all appearance are perfectly safe.

In our cold pits, where the cuttings are striking, and the bases swelling, where a little whitening was put on the glass, we have removed the whole or the most of it, as the sun will not be too powerful for them now, and the cuttings will keep shorter and sturdier in consequence. Ere long we must remove many summer plants from the corridors and the conservatory, and replace them with winter plants. Now Heaths should be kept from rains, as too much wet and a deficiency of air will bring on mildew. These can rarely be kept in too airy a house, and direct air, even when rather cool, seldom does them any harm. Many hardwooded plants, however, though delighting in fresh air, as Leschenaultias, Boronias, Crowsea, Gompholobiums, &c., like a higher temperature than Heaths, and do not like a draught of cold air coming directly upon them. They should rarely in winter stand opposite front openings that communicate directly with the open air. A draught in which most Heaths would delight, would soon injure such as these, when blowing on them at once. Proceeded with potting, &c., as detailed in previous weeks' noticce.—R. F.

COVENT GARDEN MARKET.—October 6.

We have no improvement to report. Stocks are heavy and business quiet, inferior articles being scarcely saleable.

TRADE CATALOGUES RECEIVED.

W. Rollisson & Sons, Tooting, London, S.W.—*Catalogue of Cape, Dutch, and other Bulbs, Roses, &c.*

Thomas Mc Kenzie & Sons, 31, Dawson Street, Dublin; Belfast; and Cork.—*Descriptive Catalogue of Dutch and other Flowering Bulbs, &c.*

H. Lane & Son, Great Berkhampstead.—*Descriptive Catalogue of Roses, Fruit Trees, American Plants, Conifers, Azalea indica, &c.*

John Scott, Merriott Nurseries, Crewkerne, Somerset.—*The Orchardist, or a Cultural and Descriptive Catalogue of Fruit Trees.*

TO CORRESPONDENTS

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c., 171, Flee Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Gardeners' Year Book (*C R.*).—Your friend was correct. It contain a descriptive list, not only of fruits but of plants, &c., introduced during the previous year. You can have it post free from our office if you enclose fourteen postage stamps with your address.

Asparagus Kale (*A. C., Croydon*).—What you have for Asparagus Kale is Convo Tronchuda, or Portuguese Cabbage. It is sometimes called Asparagus Kale, the thick, fleshy ribs of the leaves being the parts used like Sea-kale; but the true Asparagus Kale is Chou de Milan, which in the spring produces long succulent shoots like Asparagus.

White Grape (*J. W. Peglar*).—Your Grape is not White Tokay, but one of the numerous white vintage Grapes of the south of France, and of no value as a dessert fruit. We cannot say positively which it is, but it evidently belongs to the Espagnins. Graft it with something better.

Colour of Grapes (*N. H. P.*).—A full supply of sap and exposure to light, and abundance of fresh air, secure to Grapes their proper colour. You will find the colouring of flowers, leaves, and fruit fully discussed in Johnson's "Science and Practice of Gardening," from which the following is extracted:—"Mr. Smithson's experiments, and those of M. Schubler, seem to indicate that the colouring matter of flowers and fruits is fundamentally blue—rendered red by acids or the addition of oxygen, or yellow by the presence of an alkali or the subtraction of oxygen. Mr. Smithson says, that the colouring matter of the Violet is the same in the ruddy tips of the Daisy, Pelargonium, blue Hyacinth, Hollyhock, Lavender, and various Plums, in the leaves of the Red Cabbage, and in the rind of the Salmon Radish. The acid which causes the red tint seems to be usually the carbonic."

Grapes Spotting (*Sophia*).—The cause usually is a defective supply of sap to the berries. The roots of the Vine, either from being too deep in the soil, too cold, or too dry, are not sufficiently active.

Fruit Trees for Pyramids (*W. Green*).—The following will suit you. Plant in the course of this month. We have added the times of ripening. *Pears:* Citron des Carmes, August; Beurré d'Amanlis, September; Louise Bonne of Jersey, October; Seckle, October; Van Mons Léon le Clerc, November; Fondante des Charneu, November; Beurré Berckmans, November to December; Winter Nelis, November to February; Beurré Sterckmens, January and February. *Apples:* Ashmead's Kernel, November to May; Cockle Pippin, January to April; Cornish Gilliflower, November to May; Lamb Abbey Pearmain, December to April; Nonpareil, January to May; Sturmer Pippin, January to June. *Plums:* Green Gage, Jefferson's, Coe's Golden Drop, Late Rivers, Damson. *Cherries:* Early purple Gean, Black Tartarian, Bigarreau, Late Duke.

Gardeners' Examinations (*Freirmoin*).—If you write Mr. Richards, Assistant Secretary, Royal Horticultural Society's Office, South Kensington, he will send you the necessary information. If in addition to your eight years' practice you make yourself master of the contents of the books you name, you ought to pass a good examination.

Pelargoniums (*W. A.*).—No list was enclosed with your note. We answered your query about Cyanophyllum on page 252. (*Ignoramus*).—All the so-called "Scarlet Geraniums," all the Zonals, Tricolors, &c., are Pelargoniums, and very near relatives of the Pelargoniums raised by Gaines, Beck, Hoyle, and others.

Seedling Pelargonium (*A.*).—The petals had all fallen. We think the colour is salmon pink. There are many of the same tint; but, perhaps, the nearest to your seedling is Monsieur Rendatler.

Mr. Cannell's Fuchsias.—The Fuchsias are very fine, the calyx and tube very deep-coloured, but there seems a coarseness and want of elegance. If the habit of the plants be good, and they are free-flowering varieties, they will be a great acquisition. Many of these large-flowering kinds are very shy in producing their blossoms.

Ranunculuses in Pots (*Iris*).—We do not advise their culture in pots, though it may be practised; 6 or 7-inch pots are the most suitable. They should be well drained, and if they are deep in proportion to the width, all the better. Use a compost of two parts turfy loam, strong rather than light, one part old cow dung, and one part river sand. Pot at once, as we suppose you want them for forcing, filling the pots to within 2 inches of the rim; then sprinkle a little sand on the surface, and place the roots on it, pressing them gently. Put three in a 6-inch, and five in a 7-inch pot, and cover them just over the crowns with sand, and then fill to the rim with soil. Plunge the pots to the rim in ashes

out of doors, and they may eo remain until Christmas, a little dry litter being placed over them in severe weather, but remove it whenever the temperature is mild Atont Christmas the pots may be set on a shelf in a greenhouse, and a moderate supply of water should be given at first, increasing it as the plants grow, and when advanced for bloom a good supply of water should be given. The best tubers for forcing are those which have rested early .for forcing early they ought to be potted in Augus t,and may then be introduced into the greenhouse in November; they will flower in February or March. Tubers which have been kept a year over the season of planting are best for very early forcing, as they are more easily excited. They may be potted in August, and placed in the greenhouse six weeks afterwards ;and by introducing them at different periods, bloom may be kept up from November to March. A window will do if you have no greenhouse.

IRISES IN POTS (*Idem*).—They will succeed in pots. Pot them at once. The pots need not be larger than sufficient to contain the bulbs well, and three or more may be placed in a pot. Drain the pots well, using a compost of equal parts of turfy loam, leaf mould, and sandy peat, with about one-sixth of sharp sand. Cover the bulbs about an inch deep, placing sand round them. In other respects the treatment advised for the Ranunculuses is applicable to the Iris.

CONCRETING FRUIT-TREE BORDER (*F. H*).—We would not take out the soil deeper than 2 feet 6 inches, or 3 feet, and that will in some degree help to raise the border, which we would elevate somewhat above the surrounding ground level. The bottom of the border should incline from the wall to the front. 1 foot in 12 feet will be a sufficient incline. Along the front you will need a drain, and you should leave a sort of channe lto receive it. The drain must not be laid until the bottom has been concreted, therefore you will allow fall for the drain accordingly. You may concrete the border in parts, taking care to keep the proper levels. Having made the excavation, put in a 3-inch layer of coarse gravel, ram it firm ,and then ron with concrete, formed of nine parts gravel and one part unslaked lime; slake it, and cover it with the gravel, then add sufficient water to bring the concrete to the consistency of very thin mortar; a thickness of 3 inches of concrete will be necessary. It ought to be made so thin that it must be carried in a bucket. The gravel used should be of the same kind as put upon walks. Let the concrete stiffen a little until it will bear treading upon; then roll it firm, or ram it hard, leaving a smooth surface. Let it stand until firm, and then finish with an inch thick of fine gravel mixed with lime, in the proportion of one part lime to three of gravel, and this mixture cannot be too soft. When it becomes stiff and hard, as it will do in a few days, put in the rough stones for drainage, not less than 6 inches in thickness, and the drain along the front, which should be placed on the concrete and be covered with the drainage. If you do not object to the expense, one part in six of Portland cement added to the lime and gravel for the last 1-inch coating would be more certain to prevent the roots penetrating the concrete, though we never knew them pass the lime and gravel. In place of 1 inch thick of lime and gravel, you may have a layer half an inch thick of Portland cement one part, and fine gravel three parts. This when run and dry will resist anything, but it would be more costly.

LIME WATER FOR EXPELLING WORMS (*J. A.*).—Over 12 lbs. of fresh lime pour thirty gallons of water, stir well up, let the liquid stand forty-eight hours, and then, having stopped the holes in the pots with clay, deinge the soil with the clear lime water only, and the worms will come to the surface. Remove the clay from the pot holes after six hours, taking care to make the drainage free.

WORMS IN LAWN (*R. B. N.*).—Water it with lime water, made by placing 12 lbs. of fresh or unslacked lime in a hogshead, and pouring thirty gallons of water over it, stirring it well up, and allowing to stand forty-eight hours. The lawn is to be watered with the clear liquid by means of a rose watering-pot during damp weather, giving a good soaking the evening succeeding one upon which a good watering has been given. Ammoniacal liquor diluted with six times its volume of water, will answer even better than the lime water; but it has the disadvantage of making the lawn look brown for a time. Both act by bringing the worms to the surface, whence they may be swept up and cleared away.

TAKING UP GLADIOLUS BULBS (*J. Watson*).—The bulbs should be taken up when the foliage begins to turn yellow. This is better than allowing them to remain until the leaves are quite dead; and a better plan than either, in all well-drained soils, is to leave the bulbs in the ground all the year, and give a 3-inch mulching of leaf mould in November. In wet soils, however, it does not answer.

TAKING A HORNETS' NEST (*X., Sidmouth*).—Have you no one with the courage to wrap a cloth round the nest at night, remove it from the beam in your barn, and drown the inmates in a bucket of water? If not, procure some strips of pasteboard and dip the ends in melted brimstone, not prepared sulphur, but what is known as stone brimstone. The pieces of pasteboard may be about 3 inches long, and should when dipped be placed on short pegs with a notch in them. Take a bee hive, wet it inside, put the sulphur in its top inside, which will become the bottom when the hive is inverted, and cover the hive with a cloth large enough to envelope it. The cloth should have strings so that it can be tightly tied to the hive, and in the cloth where it covers the bottom of the hive have a hole in the centre about 6 inches in diameter. Put the hive on a pitchfork, light the brimstone matches, cover with the cloth, and place it so that the opening in the cloth will include the hole in the hornets' nest, press it gently or keep it close to the nest. The brimstone fumes will pass from the hive through the opening in the cloth to the hornets within the nest, and you may in a few minutes remove the nest without fear of its inmates.

GLADIOLUS BLOOMING IN JUNE (*J. R. P. Tilburston*).—The Ramosus section of Gladiolus bloom early, and doubtless from your description yours is one of them.

ROSES FOR A SOUTH WALL (*A Subscriber*).—The wing walls to your conservatory will answer well for Roses *Tea-scented*—Gloire de Dijon, Climbing Devoniensis, Maréchal Niel, Madame Falcot, Niphetos, Narcisse, and Safrano. *Noisettes*—Céline Forestier, La Biche, Lamarque, Ophirie, Solfaterre, and Cloth of Gold. We should prefer them on their own roots. The best soil is a moderately strong loam, but not very heavy, that being best which is taken from the top of a pasture about 4 inches thick, turf and all enriched with a fourth part each of cow dung and leaf soil, adding about one-sixth of sharp sand. The turf should be chopped rather fine, and the whole well incorporated, planting in a little old turf.

CLIMBING DEVONIENSIS ROSE NOT FLOWERING (*An Amateur*).—We would not lift the plant but merely thin out the shoots where too crowded, and not shorten these much ,merely removing the unripe points. It very likely will bloom finely next year; besides, it is better for a plant to make vigorous growth after planting, than to make poor growth and bloom soon after planting. If it do no tflower next year you can lift it in the, autumn. It is a very vigorous grower, but is it not grand, both in foliage and flower?

MADAME DE ROTHSCHILD ROSE (*Idem*).—I is a good light Rose, and opens freely, and from its habit we should think suitable for a cold climate. Xavier Olibo would also be suitable.

HYACINTHS TO FLOWER AT CHRISTMAS (*Idem*).—To have them flower at Christmas, the bulbs potted about three weeks ago should be placed in heat at the end of October, or beginning of November. The slower they are brought forward the finer they will be, and they cannot be kept too near the glass, or have too much air; 45° at night will be sufficient excitement for three weeks, then raise it to 50°, bringing them into bloom with a temperature of 50° to 55° at night and on dull days. Narcissus and Tulips succeed under the same treatment, giving an abundance of air and light to keep them from drawing.

GRUBS AND CATERPILLARS DESTROYING CABBAGE PLANTS (*J. B, Enfield*).—The grubs are, no doubt, the leather coat, a brown short grub. The only remedy is to pick away the soil from about the plants and secure the pests, which when disturbed roll themselves into a sort of ball. They eat off the stem of the plants close to the surface. An intelligent lad will take an immense number in a day. For the caterpillars we do no tknow of a better remedy than dusting with fresh lime early in the morning while tthe leaves are wet; but if you have tried that two or three times and it fails, we would advise hand-picking, which though a tedious is a certain mode of riddance.

WORMS IN POTS (*W. A. O.*).—See answer to another correspondent, "J. A." in to-day's Journal.

CAPE JASMINE (*Idem*).—The shoot of the Gardenia florida sent has a bloom-bud at its point, which will give the flowers of next spring. You must not now cut away the shoots, as from their points are produced next year's flowers.

LIBONIA FLORIBUNDA (*Idem*).—To have it flower in winter a good growth should have been made, and have it well matured by exposure to light and air, affording a period of rest for at least six weeks, by keeping drier and closer before exciting into growth, for which a temperature of 60° to 65° at night, and 70° to 75° by day is necessary, with a moist growing heat. Afford a light airy position, and do not overwater, but keep the soil moist. Good drainage is necessary.

SCHIZOSTYLIS (TRITONIA) COCCINEA TREATMENT (*Idem*).—It is a bulbous plant and flowers in autumn, and continues into winter. It is best treated as a half-hardy plant, though it is quite hardy. Pot it now if it ie not flowering, and keep it in a cool greenhouse through the winter, giving a good watering after potting, and do not allow the soil to become dry in winter. In potting do not disturb the roots, but pot with the ball entire, merely removing the surface soil, the drainage, and the loose soil. A compost of two parts turfy loam, one part old cow dung, and one part peat, with one-sixth of sharp sand will grow it well. Good drainage is necessary; cut away the old stalks as they become yellow close to the soil. If it is flowering, pot when the flowering is past. When growing freely, water copiously and sprinkle with water twice a-day to keep down red spider. After May move to a sheltered position out of doors, or grow in a cold pit, taking into a cold house for flowering, and it will bloom for weeks.

AQUATICS (*D. H.*).—In a smoky atmosphere we have grown the following:—Nymphæa alba, white, 2 to 3 feet; Nuphar lutea, yellow, 18 inches to 2 feet; Aponogeton distachyon, white, 1 to 2 feet; Alisma plantago, purple and white, 1 foot; A. natans, white, 6 inches; Acorus Calamus, flowers apetalous; Butomus umbellatus, pink, 1 foot or margin; Caltha palustris, flore-pleno, yellow, margin; Cyperus glomeratus, 6 inches; Iris pseud-acorus variegatus, 1 foot or margin; Myriophyllum spicatum; M. verticillatum, green, 1 foot to 2 feet; Menyanthes trifoliata, white, margin; Hottonia palustris, flesh, 6 inches and margin; Lysimachia thyrsiflora, yellow, 6 inches and margin; Villarsia nymphoides, yellow, 2 to 3 feet; Statices aloides, white, 6 to 18 inches; Ranunculus aquatilis, white, 6 inches; Potamogeton densum if you wish to have the surface all green, if not avoid the last. They may all be procured through any of the principal London or provincial nurserymen. We cannot recommend dealers.

TULIPS PLANTING (*H. F.*).—You may pot each bulb in a 4-inch pot, and plunge the pots in soil 1 inch above the rims. We would put in a few rough cinders in each pot for drainage, and that will allow of the roots to some extent passing out, whilst enough of roots will be preserved in the pots to allow of their being removed after flowering. They and the Narcissus should be planted this month, and not later than the beginning of November. 6-inch pots will be necessary for the Narcissus.

NAMES OF FRUITS (*F. L. A.*).—2, Kirke's Lord Nelson; 4, Manks Codlin; 5, Herefordshire Pearmain; 6, Winter Quoening; 7, Sturmer Pippin; 8, Norfolk Beefing; 9, Dutch Codlin; 10, Keswick Codlin. (*Inquirer*).—1, Baronne de Mello; 2, Beurré Giffard; 3, Dunmore. (*Centurion*).—1, Catillac is correct; 2, Beurré Diel; 3, Franklin's Golden Pippin; 4, Certainly not Easter Beurré. It appears to be Verulam; 5, Suffolk Thorn; 6, We are in doubts about this. It is very much like Triomphe de Jodoigne; 7, Glou Morçeau; 8, Frizzled Nut; 9, Reine Claude de Bavay is quite correct. (*W. Noble*).—1, Beurré Letèvre; 2, Nouvean Poitean; 3, Urbaniste; 4, Beurré Superfin. (*Avonitensis*).—1, Beurré Diel; 2, Napoléon; 3, Unknown, worthless; 4, Flemish Beauty; 7, Soldat Esperen, (*W. Cutbush & Son*).—Headcroft Seedling. (*E. A. W.*).—1, Catillac; 3, Van Mons Leon le Clerc; 4, Bergamotte Esperen; 6, Beurré Diel; 7, Beurré Nantais; 8, Van Marum; 9, Triomphe de Jodoigne; 10, Fondante d'Automne. (*E. A. L.*).—1, Easter Beurré; 2, Colorée d'Août; 3, Lucien Le Clerc.

NAMES OF PLANTS (*Black Bantam*).—It is one of the many variations but an uncommon one, of Scolopendrium vulgare, Hart's Tongue. (*Rev. E. H.*).—It is quite impossible for us to name florists' flowers. They are in legions, and floriste themselves have great difficulty in identifying them, even when they see an entire plant; they so nearly resemble others. (*A. Green*).—1, Cyrtomium caryotideum; 2, Cyrtominm falcatum; 3, Genista canariensis; 5, Tussilago japonica. (*E. J. Birmingham*).—We cannot name plants from their leaves only.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending October 5th.

Date.	Barometer.		Thermometer. Air.		Earth.		Wind.	Rain in inches.	General Remarks.
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.			
Wed... 29	29.580	29.514	76	55	58	56	S.	.02	Very fine; clear and very fine; densely overcast.

POULTRY, BEE, AND PIGEON CHRONICLE.

LONDON POULTRY SHOW.

A meeting of those interested in the above was held on Tuesday last, at Evans's Hotel, Covent Garden, Mr. Esquilant in the chair. Amongst those present were Messrs. James, Jones, Crooke, Ford, Hans, Toby, Hale, Boutchere, Esden, Fulton, Wright, Hastelow, Howard, Waller, Burge, Davis, Wright, &c.

It was the unanimous agreement of those present, that a Poultry, Pigeon, and Rabbit Show should be held in the metropolis during the present year, provided there be a sufficient guarantee fund raised to warrant a Committee commencing without the fear of a considerable pecuniary loss to themselves.

The feeling of the meeting was decidedly in favour of holding the Show during the Cattle Show week, and, if possible, at the Floral Hall, Covent Garden, but as there appeared to be a doubt whether the proprietors would let the Hall for such a purpose, through the objections made by several residents of the neighbourhood; among a number of other places suggested the Crystal Palace was named as a most suitable place, and likely to draw a large attendance of visitors.

A Committee was then appointed, composed of the following nine gentlemen, with power to add to their number—viz., Messrs. Esquilant, James, Jones, Crooke, Ford, Tegetmeier, Hans, Howard, and Esden, who will report at a general meeting to be held on the 19th inst., at 4 P.M., at Evans's Hotel, the place they consider most desirable for the Show, and the amount of support they have received towards the guarantee fund and other expenses, also an estimate of the cost of the whole Exhibition. Decided steps to be then taken if the Show is to be held this year.

The sum guaranteed at the meeting was about £50. A prize of £10 from the *Field*, another of £5 from *Land and Water*, and nearly another £10 was promised by some of the gentlemen present towards the prizes and expenses. The Proprietors of The Journal of Horticulture will also give a prize, or contribute £10 towards the expenses.

There now seems every chance of the Exhibition being started with little fear of a failure, but this will, of course, depend in a great measure upon the activity of the Committee. Those present expressed their surprise that a similar meeting had never been held, and this in some way may account for previous failures at attempts to hold a Show in the metropolis.

A FEW DAYS IN A CHICKEN DISTRICT OF SUSSEX.

"They must manage them better in Sussex." "Then why do you not go there and inquire?" To this home response no ready rejoinder rose to my mind, and then the querist added, "You are fond of antiquities, you are fond of rustic simplicity, you are fond of shooting, you are fond of poultry-keeping, so, why not go with me to-morrow?" There was no adverse reason, so my gun-case, portmanteau, and self, were at the Victoria Station, and by two of the afternoon of the day following I was in the parish of Heathfield, in the county of Sussex.

I wonder how many of your readers know where that parish lies, for it is six miles from a railway station, and never had a stage coach run through any one of its widely separated margins. Well, there I was, and there I shot, and there I feasted on home-laid eggs, home-made butter, home-made bread, cream as thick as hasty pudding, vegetables fresh cut, and chickens such as Sussex breeds. Ah! there's the subject of my special research. "They must manage them better in Sussex." That observation resulted from reading a letter written by a well-known poultry-fancier, stating that "only twenty chickens were reared of eighty-five that were hatched." However, I shall tell my story in my own way, and any one objecting to my preface can "skip" to the more practical portion. If I am prosy I like to be prosy, and if you do not choose to permit me to be prosy, don't print my notes.

The two-miles walk from my friend's farm to Heathfield church is across fields, and over hills and dales, through farmyards, and by the side of plantations that would have made a misanthrope smile that day, so gladsome were they in the unclouded sunshine. The church was reached, the keeper of its key was found, and the key was placed in my hand, and I was allowed to enter and remain in the church quite unattended. I might have carried off all its bibles and prayer books unhindered. This was no carelessness, no want of vigilance, but the result of people honest, confiding in the honesty of others. Thus for days I went into the sheds among the cooped chickens in the neighbourhood. There were hundreds of chickens, every door open, and not a living human being in the houses of the owners. They were all away "hopping!" The honesty prevails even where it is rarely met with—namely, in the epitaphs, for in the church chancel on a marble slab to the memory of Thomas Courthope, and Mary his wife, without any dates or other verbiage are appended these lines—

"A happier couple
There never was wed,
But much more so
Now they are dead."

Let us hope that this is true, but it savours of honesty refraining from suggesting that any regret was felt by their survivors.

The very iron that used to be here manufactured—the hills are full of iron ore, and the springs chalybeate—was the most honest iron of our foundries. It was the hardest and toughest, cannon made from it would bear a heavier charge than cannon made from the iron of other localities. Lord Heathfield, whose memorial tower is on the hill to the right as I descended from the church, could bear testimony to this, as the defender of Gibraltar. His choice of title and residence here were thus far appropriate, and looking from his mansion's windows upon Warbleton church, he there saw where one of the district's most celebrated iron-founders, Richard Woodman, was confined previous to his martyrdom at Lewes.

I have not said much as yet about chickens; and before I say more concerning them, let me tell any brother pilgrim straying to Heathfield, to notice within as well as without the over-shot watermill at the base of the church hill. For picturesque position, and for antique formation, it cannot be exceeded in all England. The miller told me it is known to have been there more than four and a half centuries. He, like everyone around, is a breeder of chickens, and there in one of his sheds were a lot of them in the horseshoe-shaped coop peculiar to the district, waiting to be fetched away by some local fatter of poultry. They were made of the horseshoe form to fit round the waist of a man, with a leathern suspender over his shoulders. That was in days when the collectors were pedestrians, and the form remains unaltered, though better roads, and the greater number of chickens to be collected render feasible the employment of horses and carts for the purpose.

This is a district of none but small, very small, farms, and labourers' cottages, and I commend all those who take an interest in answering the question, "Are small farms desirable?" to sojourn here and judge from the evidence attainable by his own eyes and ears.

These small-farm holders, and these cottagers, are all breeders of chickens. The coops are to be seen on the grass verges by the sides of the roads, and the corners of the fields; there are hundreds of these coops in the parish of Heathfield. The

breeders are not fatters of chickens, but the fatters journey round at stated intervals, and collect the chickens of an age fitting them for the fatting-coop. The fatters are not those who send the chickens to the London market, they only fat, kill, and pick them, ready on a stated day for the higgler to fetch them, pack them, and send them to London. The productiveness of this district of chickens is evidenced by the fact, that two higglers in the village of Heathfield send between them one hundred dozen of chickens three times a-week to London —that is, 3600 chickens weekly. One of these higglers alone once sent to London all at one time, 105 dozen of chickens. This was the largest consignment ever known there to have been made by one man.

The variety of fowl universally bred here, and popularly known as "Sussex fowls," are Dorkings in form, minus the extra claw, and neither entirely dark nor entirely white-feathered. The ground colour of the plumage is white, but thickly and irregularly marked with feathers black and brown. They are white or grey-legged, and with a very large development of muscle on the breast—that is, as was expressed by my informant, "the breast's very meaty." They are a hardy breed, but it is a hardiness arising from robust health, for I saw on the 25th of September a Dorking hen drafted from Lady Holmesdale's celebrated stock, with a brood, all from her own eggs, of sixteen. They were six weeks old, all white speckled with black and brown; she had sat upon seventeen eggs, their sire was a Sussex cock, and not one had died. On the same day at a cottager's by the roadside I saw a brood of twelve not a week old.

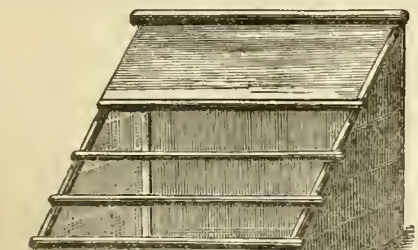
Hatching goes on all the year round; but they generally like to have a brood at the beginning of February, which may be called the first of the season, and as long as eggs can be obtained, and hens are broody, hatching proceeds, and even at Christmas small chicks are quite common. At this season the hen and chicks are kept in a dry and warm place, a waggon lodge being considered as preferable a place as can be found. The great thing is to let them have plenty of room and air.

The ordinary sitting is thirteen eggs, and fifteen is very common; but ten and twelve are the usual numbers. It is preferred to have the nest on the ground, but if a hen has selected one elevated from the earth, the eggs are sprinkled with water daily when she leaves the nest, and a little fresh grass placed under them.

How long the hen is confined under a coop depends on the season; during fine weather, and in the height of summer, about four or five weeks.

The chickens are fed three and four times a-day, and oftener whilst small. Whilst small chicks they are fed at six o'clock in the morning. The food given them is ground oats made into a thick paste with water.

The hens and chickens under coops by the roadside, and elsewhere, are left out all night. The coops are uniformly of this shape, are about 2½ feet long, 2 feet wide and the same in



height. They are close-boarded at each end and at the back, and partly so at the top in front, so as to form a sheltering roof. A board is put in during wet weather for the hen to brood the chickens on.

The fatters of chickens have them in an enclosed shed, and there in coops down its two sides and one end—coops formed entirely of rails, and so narrow that when their heads are in the feeding trough outside the coop their tails press against its back—they are fatted in about ten days. They are fed twice daily on ground oats made into a thick gruel with milk.

Under this system of management from the nest to the fatting coop the deaths are so few as not to be noteworthy. Why does this result stand out in such enviable contrast to the mortality usual in the poultry-yard of the amateur? I have no doubt it is because the parents are more healthy and vigorous than those kept in confined, stuffy enclosures, and because the chickens breathe nothing but pure air, and have healthful exercise in their search for insects and other food. The chickens reared by amateurs, like the children reared in London courts and alleys, have a diseased or sickly parentage, and have to breathe air contaminated by the exhalations and excreets from many bodies.

The soil about Heathfield is clayey, and, therefore, not such as is most conducive to animal health; but most of the springs are chalybeate, which may have a tonic influence over the fowls. These facts enforce the importance of keeping very few in a small space; to have that space ventilated as much as possible; cleaned thoroughly daily; fresh gravel spread over the surface frequently; some rusty iron to be in the drinking water, and that water changed daily.

There is no exaggeration in my statement of the non-mortality among the Sussex-bred chickens, for I especially pressed the inquiry, and the last hen-wife inquired of seemed staggered at the question when asked how many chicks she lost out of a hundred hatched. A latent smile played about her lips as she stuttered out, "How do you mean, sir?" On repeating the question more explicitly, as she appeared not quite to comprehend the first form of it, she replied, "Well, I don't know as ever I lose any, sir." "How many have you reared this year since spring?" "Over two hundred." "And how many of them did you lose?" "I think I did lose one, but it was always weakly." She added that through the winter chickens require a little more looking after, by keeping them in a dry and "warmish" place, which means a cart-lodge or some such shelter. Chickens, she observed, want to be often moved on the ground, and they should never be allowed to remain long enough for it to become "stenchy." Too much food should never be given at a time, but little and often; and they should always have "cleared out" before more is given.—G.

OSWESTRY POULTRY SHOW.

Perhaps one of the chief features of the Oswestry Show, which took place on the 1st inst., was the class for Dark *Brahmas;* and this is the more remarkable, as this useful variety of poultry has hitherto been comparatively unknown in the district. Grey *Dorkings* were especially good, but it was a matter of regret to find a pen of fearfully roupy White Dorkings entered in this class. Very properly the birds were at once repacked by the Committee and returned to their owner. They had evidently been diseased for a considerable time, and it is a pity they should have been forwarded at all, for it is well known no ailment of poultry is so easily communicated by infection, or so very difficult to eradicate. A glance at the names of the competitors in the Aylesbury *Duck* class will convince our readers that it was one of the best in the show tent. Many of the *Game* fowls well maintained the high reputation which the district enjoys for this breed of poultry, and the condition in which they were penned was faultless. The weather was bright and sunny, and the meeting most successful.

CHICKENS.

Game (Black or Brown-breasted Red).—1, W. Perrin, Nantwich. 2, S. White, Oswestry. *hc*, P. A. Beck, Guilsfield. *c*, Rev. P. G. Bentley.

Game (Duckwing Grey and White or Piles).—1, Mrs. E. Winwood, Worcester. 2, T. Dyson, Halifax.

Dorkings.—1, Rev. E. Bartrum, Great Berkhampstead. 2, E. Shaw Plas Wilmot, Oswestry.

Cochin-China (Brown or Partridge).—1, C. Sidgwick, Ryddlesden Hall, Keighley. 2, Miss Story, Lockington. *hc*, J. K. Fowler. *c*, E. Shaw.

Cochin-China (White or Buff).—1, C. Sidgwick. 2, C. Banbury, Penfields, Wolverhampton. *c*, J. L. Williams, Llansilin.

Spanish.—1, Tonkin & Tuckey, Bristol. 2, F. James, Peckham Rye. *hc*, H. & S. Cooper, Walsall. *c*, J. Clews, Walsall.

Brahma Pootra (Dark).—1 and 2, H. B. Morrell, Caemawr, Clyro. *hc*, E. Leech, Rochdale; W. B. Etches, Whitchurch; C. Leyland, Morrisbrook, Warrington; W. Gamon, Chester.

Brahma Pootra (Light).—1, L. H. Ricketts, Banwell. 2, T. A. Dean.

Hamburghs (Silver or Gold-pencilled).—1, A. Woods, Sefton, Liverpool (Silver-pencilled). 2, W. Speakman, Nantwich (Golden-pencilled). *c*, H. Worthington, Aigburth (Silver-pencilled).

Hamburghs (Silver or Gold-spangled).—1, E. Brierley, Heywood, Manchester. 2, T. Blackman, Tettenhall. *c*, S. & R. Ashton, Mottram; T. May (Gold-spangled).

Crève-Cœurs.—1, Mrs. M. Seamons, Hartwell, Aylesbury. 2, E. Williams, Henllys, Berriew.

Houdans.—1 and 2, W. O. Quibell, Newark.

Any other Distinct Variety.—1, C. Sidgwick. 2 and *hc*, W. Gamon (Polands).

Game Bantam.—1, J. Atkins, jun., Walsall. 2, T. Dyson. *c*, W. B. Etches.

Bantam (Any other variety).—1, Rev. G. F. Hodson, North Petherton, Bridgwater (Gold-laced). 2, H. Yardley, Birmingham (Sebrights). *c*, S. and R. Ashton; Miss N. Platt, Dean, Bolton.

Turkeys.—Prize, E. Leech.

Geese.—1, M. Seamons. 2, E. Leech.

Ducks (Aylesbury).—1, S. H. Stott, Rochdale; 2, J. K. Fowler. *hc*, E. Leech; M. Seamons; J. K. Fowler.

Ducks (Rouen).—1 and c, W. Gamon. 2, J. K. Fowler. hc, L. H. Ricketts.

Selling Class.—1, 2, and c, E. Shaw.

LOCAL CLASSES.

Game (Black-breasted).—1, J. Crutchloe, Oswestry. 2, S. White, Oswestry. c, E. Shaw.

Game (Any colour).—1, E. Shaw. 2, J. Crutchloe. c, S. White.

Dorking.—1 and 2, E. Shaw.

Amateurs' Prizes.—1, E. Shaw, Plas Wilmot. 2, Withheld.

Edward Hewitt, Esq., of Birmingham, was Judge.

FARNWORTH POULTRY SHOW.

The following is the list of awards made at this Show held at Farnworth, near Warrington, on the 30th of September:—

CHICKENS.

Game (Black-breasted).—1, C. Chaloner, Whitwell, Chesterfield. 2, J. Halsall, Ince, Wigan. hc, G. Bagnall, near Cheadle, Staffordshire; J. Platt, Swanlow, Winsford.

Game (Brown breasted).—1, J. Wood, Meathouse, Wigan. 2, J. Platt. hc, T. Dyson, Halifax; C. Chaloner.

Game (Any other variety).—1, C. Chaloner. 2, J. Halsall (Duckwing). hc, E. Noble, Halifax (Piles).

Dorkings.—1 and Cup, E. Leech, Rochdale. 2, J. White, Warlaby, Northallerton. hc, Rev. E. Bartrum, Great Berkhampstead; Viscount Tarneor, Shillingtee Park, Petworth; E. Ryder, Harrytown, Stockport; J. Stott, Healey, Rochdale.

Spanish.—1 and Cup, F. & C. Howarth, Nowfield, Haslingden. 2, H. Beldon, Goltstock, Bingley. hc, T. Coomber, Rainhill.

Cochin-China (Cinnamon or Buff.—1, Cup, and 2, W. A. Taylor, Manchester (Buff. hc, C. Sidgwick, Keighley; T. Stretch, Ormskirk. c, J. Cattell, Birmingham.

Cochin-China (Partridge-feather, or any other variety).—1, C Sidgwick. 2, B. Bather, Parbuck. hc, C. Sidgwick; T. Stretch. c, A. Wilkinson, Queniborough Hall, Leicester.

Hamburghs.—*Gold-n-pencilled.*—1 H. Beldon. 2, W. Pierce, Hartford, Northwich. hc, W. Clayton, Morton Banks, Keighley. *Golden-spangled.* 1, J. Chadderton, Hollinwood. 2, Duke of Sutherland, Trentham. hc, J. Buckley, Taunton, Ashton-under-Lyne; T. Walker, Denton, Manchester; H. Beldon. c, J. Ogden, Hollinwood. *Silver-pencilled.*—1, H. Beldon. 2, Duke of Sutherland. hc, T. Walker. *Silver-spangled.*—1 and Cup, T. Walker. 2, J. Fielding, Newchurch, Manchester. hc, H. Beldon; N. Marlor, Denton, Manchester.

Polands (Any variety).—1 and 2, W. Gamon. hc, J. Partington (Silver-spangled); J. S. Senior, Batley Carr, Dewsbury.

Brahma Pootra (Any colour).—1 and Cup, F. & C. Howarth. 2, W. Gamon. hc, E. Leech; C. Leyland, Warrington; A. Wilkinson.

Game Bantams (Any colour).—1 and Cup, J. Crossland, jun., Wakefield. 2, W. F. Entwisle, Leeds hc, J. Crossland, jun; H. Semach, Southwell.

Bantams (Any breed).—1, T. C. Harrison, Hull. 2, N. Platt, Dean.

Any other Distinct Variety (Not included in the above classes).—1, N. Marlor. 2, C. Leyland (French).

Selling Class (Any colour or breed).—1, C. W. Brierley, Middleton. 2, G. J. Taylor, Huddersfield (Gold-pencilled Hamburghs). hc, J. Copple, Eccleston, Prescot (Dorkings); W. A. Taylor; F. & C. Howarth, Newfield, Haslingden.

Single Cocks.—*Game.*—1 and Cup, C. W. Brierley, Middleton. 2, C. Chaloner. hc, J. Wond; J. R. Fletcher, Stoneclough, Manchester. c, J. Holland, Manchester. *Game Bantams.*—1 and Cup, W. F. Entwisle. hc, J. Crossland, jun; R. B. Riley, Halifax; J. Holland; J. Halsall (Black); Harwood & Buckley.

Ducks (Rouen).—1, W. V. Kearne, Gateacre. 2, J. Dickenson, Leigh. hc, G. Bagnall, Draycott, Cheadle; J. Woods, Wigan; C. P. Ackers, Brookside, Abram.

Ducks (Aylesbury).—1, Mrs. Seamons. 2, S. H. Stott, Rochdale. hc, Mrs. M. Hornby, Swanlow, Winsford.

Ducks (Any other variety).—1, C. W. Brierley. 2, R. Gladstone, jun., Broadgreen (Carolinas). hc, R. Gladstone, jun. (Brown Calls); T. & R. Ashton, Mottram (Carolinas); J. Wood (Black East Indians); J. Young, Widnes (East Indian); C. W. Brierley. c, H. Beldon.

Geese.—1, E. Leech. 2, S. H. Stott. hc, Mrs. M. Seamons, Hartwell, Aylesbury; R. Gladstone, jun. (Greys); Rev. G. Hustler, Stillingfleet Vicarage, York (Whites); S. H. Stott.

Turkeys.—1, E. Leech. 2, T. Coomber.

The Judges were Mr. Richard Teebay, Fulwood, Preston; Mr. Joseph Hindson, Barton House, Everton; and Mr. Dixon, Bradford.

NORTHALLERTON POULTRY SHOW.

The poultry department of this year's Show, held September 30th, proved the greatest success that the Society has ever had. Not only were the classes, as a whole, remarkably good, but the day was delightful. The *Dorkings*, *Game*, and *Spanish* were generally good; of *Hamburghs* the Pencilled were far superior to the Spangled varieties. The first-prize Golden-pencilled cockerel was a splendid bird. In the *Geese* and *Duck* classes the winners were large and well framed.

Dorkings.—1, 2, and c, J. White, Warlaby. hc, W. C. Booth, Orsa, Catterick.

Game.—1, W. Bearpark, Ainderby Steeple. 2, G. & C. Lancaster, Morton Grange. hc and c, J. Watson, Knaresborough.

Spanish.—1, W. Bearpark. 2, W. Charter, Driffield. hc, W. P. Lawes, Brompton. c, J. Robson, Thornton-le-Moor.

Cochin-China.—1, J. Bell (Partridge). 2, F. H. Readman, Whitby. hc, W. Barnes, Thirsk. c, J. White (Partridge).

Brahma Pootra.—1, J. Walker, Haya Park, Knaresborough. 2, W. Severs, Kirby Fleetham, Bedale.

Hamburghs.—*Gold-spangled.*—1 and 2, J. Walker. *Silver-spangled.*—1, W. Mansfield, Thirsk. 2, W. Severs. c, J. Walker. *Gold-pencilled.*—1, W. Bearpark. 2, J. Walker. hc, R. Winterburn, Welbury c, J. Webster, Whitby. *Silver-pencilled.*—1, Rev. J. C. Wharton, Richmond, Yorkshire. 2, J. Walker. hc, T. White.

Any other Distinct Variety.—1, G. Carter, Bedale. 2, Rev. J. G. Milner, Bellerby Vicarage, Leyburn. c, J. Walker (Black Hamburghs).

Bantams (Any variety).—1, G. Gibson, Sigston. 2 and hc, G. Carter. c, J. Walker (Black); J. Watson.

Ducks.—*Rouen.*—1, Miss E. Graham, Boroughbridge. 2, T. C. Booth, Warlaby. hc, O. A. Young, Driffield. *Aylesbury.*—1, M. Harrison, Warter, Pocklington. 2, G. Robinson, Seaway, Thirsk. hc, O. A. Young, Driffield. c, W. Severs. *Any other Distinct Variety.*—1, J. Walker (Carolinas). 2, C. Rutherford, Thirsk.

Turkeys.—1, J. B. Braithwaite, Otterington House Farm. 2, O. A. Young.

Geblings.—1, O. A. Young. 2, T. C. Booth, Warlaby.

Pigeons.—*Carriers.*—1, W. Bearpark. *Pouters.*—1, J. & R. Kirby. *Jacobins.*—1, W. Peeks, Thirsk. *Tumblers.*—1, J. & R. Kirby. *Any other Distinct Variety.*—1, J. Watson. hc, W. Bearpark (Nuns). c, R. Wilson, Thirsk.

Rabbits.—*Any variety.*—1, J. T. Beckwith, Maunby, Thirsk.

Judge, Mr. G. Hutchinson, York.

PIGEONS GOING LIGHT.

In answer to several of your correspondents, I beg to re-assert that I am quite certain that every Pigeon with a diseased wing, treated in the manner I described in your Journal some time ago (see vol. xv., page 85), will perfectly recover. The experiment has been tried by several friends since, and, without exception, with perfect success.

And, now, a word about the evil called "going light," of which your correspondent, "X. Y. Z.'s," birds are dying. By repeated experiments I have discovered that it is the effect of two causes. The first is the over-loading of the gizzard by too rough gravel, and the second, impure water. The birds suffering from the first cause are continually troubled inwardly with a kind of creaking noise, caused by the friction of the gravel in the gizzard; and in two birds so affected I found, on examination, that the gizzard of the one contained eleven stones, and that of the other fourteen stones, about the size of peas, besides the usual necessary grit, and this in birds of the Owl breed. The Pigeons lingered for a month, as the stones prevented the natural passage of the food, and they died perfect skeletons. As regards the second cause of "going light," impure water renders the excrements, in colour and substance, like green paint, and, if neglected, the birds are reduced very rapidly to a dying state.

In the first case, very spare feeding with small grain, and two doses of castor oil daily, reduce the size of the gravel by natural friction, and the bird recovers; but it requires perseverance for nearly a month. In the second case a dose of charcoal powder daily, and some castor oil after it, most effectually restore the bird to health, but it must be fed very sparingly during the time; mix also some charcoal in the water. I consider feeding in troughs and giving pure water, the preventive in both cases.

The breeding season during the past summer has been very irregular in the midland counties. As far as my inquiries go, there has been a great amount of bad eggs at certain periods. On this subject I should like to know the opinions of, and results of observation by your readers.—A Foreigner.

Your correspondent, "X. Y. Z., answered at page 238, September 16th, is killing his Pigeons by Indian maize diet. The maize is too cold and watery, giving little nutriment in proportion to the bulk of excrement thrown off. All feeders of cattle and poultry ought to, or do, know this fact. The food for close-feathered and flying Pigeons is small grey peas, English (not large French) horse beans split, and wheat, mixed in equal proportions; their drink, clear well water, daily renewed; and a bathing-dish or shallow pan full of water on the roof outside is needful; the salt and gravel dish inside the cote. All old nests should be pulled away, and new straw given, and the floor of the cote scraped daily and sanded at feeding hours. Feed twice daily, say from 8 to 10 A.M., and from 4 to 6 P.M., as birds usually and naturally feed morning and evening. Syringe the cote with lime water occasionally, or Condy's disinfectant fluid and water from a garden rose-syringe.—Reader.

RABBITS AND THEIR JUDGES.

With regard to the remarks made by "One of Many Witnesses," about the Rabbits at Whitby Show; in the first place he states that "the Judges positively got through (I do not say judged), the twenty-one Rabbits in a trifle short of two minutes." Well, instead of there being twenty-one pens, there were only eleven. Fourteen pens were entered, and three, I think, were empty. As regards the time taken, I cannot say what it was,

but the matter was so very simple that there was but little time required. As regards not measuring the two Lop-eared Rabbits, there was no necessity, they were side by side, and there was no difficulty in seeing which was the better. Your correspondent does not say that the prize was not given to the best; but that we "certainly did not know, and as clearly did not care." Now, I think these remarks are quite uncalled for, unless he could show that we had erred in judging, which I am quite sure we did not. Had there been any difficulty, or had there been a large entry, of course we should have measured them, which I always do where there can be any doubt.—JAMES DIXON, *one of the Judges.*

TREATMENT OF RABBITS AT SHOWS.

As an exhibitor at the Middleton Show, I was pained to read the following lines in the notice of the Rabbits published in your Number of September 23rd.—"Might I suggest to the Committee a little more attention to the creature comforts of the specimens, remembering that some of them had travelled a great distance to the Show, and had to return, I suppose, the same distance?" The above words would not be written inconsiderately, and they mean in plain English that the Rabbits were insufficiently fed, or not fed at all. Cruel as it is, I fear this is no uncommon treatment, and I will give a case in point. The other day I dispatched six Rabbits to Whitby, and followed them the next day with some friends to see the Show. Reaching the grounds about eleven, our first observation was—that there was not a single grain or the least vestige of any kind of food in any one of the Rabbits' pens, from which we concluded that they could have had no breakfast. We were assured, however, that they were all fed very early that morning, and we could only reply that it must have been a very early or a very scanty meal, as every Rabbit had made a clean sweep of everything in the pen. Well, I hoped that a pennyworth of carrots might charitably be doled out to the twenty-one Rabbits before the day was over, but they were all packed off with empty stomachs, though the managers knew perfectly well that many of them had a long way to travel, and could not possibly reach home till sometime the next day. Mine arrived a little after ten, so that some twenty-six, twenty-eight, or perhaps thirty hours had passed since they tasted food. I was greatly struck with the fine bracing effect of the Whitby air, judging by their appetites.—GREENWOOD.

LIGURIAN QUEENS FROM AMERICA.

TOWARDS evening on the 26th of August last, a letter reached me bearing the New York post mark, which upon opening I found to run as follows:—

"New York, August 13th, 1869.

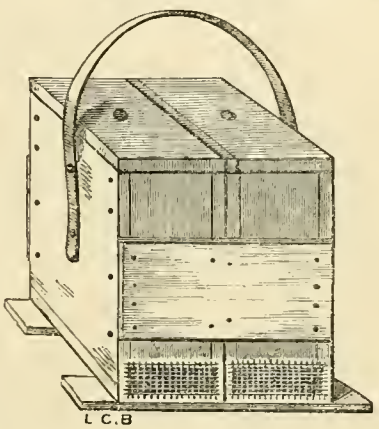
"Dear Sir,—I have requested a friend of mine to ship you two Italian queens to-morrow, bred in Mr. C——'s apiary, Colraine, Mass. . . . . I will send you Mr. C——'s surplus box in a few days, and write you more at length when less hurried.—Yours very truly, E. P.

"Let me know the condition in which they reach you.

"The bees referred to within have been delivered to J. I., ship steward of the steamer 'Erin,' which sails for Liverpool on to-morrow (14th August). The box containing the bees is addressed to you, and Mr. I. promised to take good care of it, and forward same by express on his arrival at Liverpool."

Now, this letter bothered me not a little. In the first place why should my friend, with whom I had before had the pleasure of corresponding on apiarian subjects, but from whom I had not heard for more than twelve months, wish to send me two Ligurian queens? and in the next place, what was I to do with them on so short a notice? Despatching Italian queens from America to Europe, seemed to me not a little like "sending coals to Newcastle," but after cudgelling my brains to no purpose, I failed in solving the problem, and I may add that it still remains a mystery, as I have not yet heard further from the New World. What to do with them on so short a notice was also a puzzle, for was it not most probable that the steamer "Erin" had conveyed my letter as well as the bees, and that the former would prove to have outstripped the latter merely by a few hours, or possibly only by a few minutes? Had I not also already applied for and obtained tickets for myself and family to accompany an excursion of the British Association to Dartmoor the next day, and must not I, therefore, forego this intended pleasure? On submitting this motion to the family conclave, however, I could find no seconder, but, on the contrary, was left in an ignominious minority of one, and an amendment was carried against me by acclamation, to the effect that I might be permitted to remove the queens from a couple of stocks the next morning, but only on condition that this preliminary operation should be performed so early as not in any way to interfere with the promised excursion, which must be carried out in its integrity, even if all the Italian queens in the New World were on their way to revisit their parent continent! I had, of course, no alternative but to obey, and accordingly placed the queens of one black and one hybrid stock in durance vile the first thing the next morning, and devoted the rest of the day to a picnic among the granite tors of Dartmoor, examining at the same time sundry Druidic circles, and admiring the magnificent scenery of that romantic neighbourhood.

On our return, I inquired anxiously after the expected royal visitors; but found that none had arrived, nor was it until some days afterwards—viz., on the 1st of September, eighteen days after their departure from New York, that a special messenger from the South-Western Railway Station reached my domicile soon after three o'clock in the afternoon, and placed in my hands a small package, of the external appearance of which the accompanying sketch will convey a tolerably



accurate idea. A cursory examination showed that it consisted of two small and narrow boxes (which I afterwards found measured on the inside 6 inches from front to back, by 3 inches wide, and 6¼ inches deep), made of five-eighth wood, and united together by a wide slat nailed on the back and front, and two narrower ones at the bottom, the latter of which projected about 1½ inch on either side, so as to form a wide base for the whole to stand upon. At what may perhaps be termed the front end, and close to the bottom, ventilation was afforded by an aperture in each box extending across its whole width, and three-eighths of an inch in depth; this was covered on the outside by wove wire of one-twelfth of an inch mesh, whilst a seven-eighth hole in each of the covers was secured by the same material, but of a still coarser mesh, tacked over them on the inside. Above the whole, and forming a very convenient handle, was arched a black leather strap rather more than an inch in width, and fastened by a couple of short screws on either side.

By breathing into the orifices on the top, I at once elicited so indignant a buzz from one of the boxes, as to satisfy me that the bulk of its inhabitants remained in full vigour after their three-thousand-miles trip; and accordingly, after separating the two, I turned my attention to the other box, from which I had failed to elicit any response whatever. Withdrawing the two screws which secured its cover, I carefully raised it, and as I had feared not a bee attempted to escape, nor, in point of fact, could I discern a single living one. What met my gaze was simply a wooden bar an inch broad, with sealed honeycomb attached to it, and which ran from front to back in the centre of the box, resting in a rabbet at each end, to which it was secured by screws. Withdrawing these, I raised the bar, and then found that it formed the top of a small frame 4½ inches wide by 4½ inches deep inside, and completely filled with sealed honeycomb. At the bottom of the box lay a black mass of dead bees completely choking the ventilator, but a few semi-torpid and exhausted bees nearly incapable of motion still clung to the sides of the comb, and among them, to my great joy, I discovered the queen. After having been warmed and fed, she speedily recovered, and escaping from my hand flew gaily to the window. It was but too evident, however, that she had had a very narrow escape. Out of what was originally a

company of about three hundred bees, not above a score survived, and these were so far gone that a delay of even a few hours must have proved fatal. She owed her life, indeed, to the standing instructions which I had long since given to the railway officials, never in such a case to hesitate on the score of expense about despatching a special messenger. In the present instance, to have waited for the usual parcel delivery in the evening would have deferred operations until the next day, and such a delay as this must inevitably have been fatal. As it was, I was enabled to present her forthwith to her intended subjects under the protection of a queen-cage, with every hope of a successful result.

The second box was, as may be anticipated, in every respect a *fac simile* of the first, but in this the evil effects of the prolonged confinement were far less apparent. The total number of deaths did not exceed fifty, and as nearly all the surviving bees were in full vigour, I united them with tolerable success to their future fellow-subjects, to whom I also introduced their intended new sovereign in a queen-cage.

The next day (2nd Sept.) both queens were released, and were cordially received. Six days afterwards, I found that they had commenced egg-laying very copiously considering the advanced season—one extending her operations to three, and the other to four combs, and this day (1st October) a few of their worker offspring are showing outside the hives.

It now only remains for me to run counter to the proverb, which recommends us "Never to look a gift horse in the mouth," by expressing an opinion on the merits of the two queens, which have been so kindly and so unexpectedly presented to me. I may say at once that both are fine queens, and that either of them will compare favourably with any that I have ever received from the Continent; but with regard to the larger of the two, the one which had so narrow an escape from a fatal termination of her journey, I will say yet more, for I think she is the handsomest queen I have ever seen. She is, indeed, truly of a golden yellow colour, and has nothing approaching black about her, since even the very extremity of her abdomen merely darkens off to a deep rich brown. The workers also seem quite worthy of their parentage, but of these little has as yet been seen by—A Devonshire Bee-keeper.

P.S.—I should add that I consider the mode in which the bees were packed and provisioned for so long a journey, a masterpiece of ingenious contrivance most skilfully carried out. The only improvement which I can suggest is, that the lower ventilators would have been better raised—say an inch from the bottom, so as not to become choked by the accumulation of dead bees.

BEES EXPORTING HONEY.

Perhaps one of the most singular cases ever recorded occurred this season in a gentleman's apiary near my place. The hive in question was one which was bought from a dealer in bees two years ago, and which never did any good. All the summer of 1868, the hive of bees no more than kept itself alive. I noticed that it appeared during the whole summer as if strange bees were troubling it, but then there was nothing to take, and as I saw no bees killed I thought it would hold out against any invasion; but it never had more than just as much as kept it alive until the end of the season, when a little sugar was administered, of which it took very little, and by the end of January its store was again exhausted. In the beginning of February what appeared to be regular robbing took place; but on the gardener examining the hive he found to his surprise, that instead of robbing, the bees of a hive standing close to it were actually carrying food to the stock now dead, and had already filled up a considerable space of comb with honey from their own hive. I think, therefore, there is no doubt that it was from this source that the bees had been enabled to keep themselves alive during the previous summer, and I deem it one of the most unprecedented occurrences that I ever met with.—A Lanarkshire Bee-keeper.

OUR LETTER BOX.

Plumage of Houdans (*H. B.*).—Houdans may be dark or light, so far as colour is concerned, but they must not be self-coloured; the preferable colour is a mixture of black and white, in about equal proportions. Dark birds get lighter as they grow older. The top-knots should be black and white; the body square, very like that of a Dorking; the legs speckled, the feet five-toed, but the legs should be short. A mixture of straw-coloured feathers is tolerable in the cock, but no bird should be kept that has a red one. Oats ground as you describe are very unprofitable, and only hunger will induce fowls to eat them; the husk should be ground as fine as the grain. Sussex is the only place we know where it is properly done. There is an excellent miller at Slaugham, near Crawley.

Characteristics of Brahma Pootras (*T. A. D.*).—The difference in points between Light and Dark Brahmas exists only in colour. The former should be quite white, with the exception of the tail, hackle, and flight feathers. High-class specimens should be pea-combed and free from vulture hocks. The feathers on the legs should be light. To prepare them for exhibition, they merely require generous food to gain weight and condition. Eschew potatoes, rice, or inferior corn. Give good ground oats slaked with milk, cooked meat chopped fine, and at times a little bread. You may wash their feathers with a sponge or flannel, warm water, and soap. Be careful not to wet the inner plumage; it is only the exposed part of the feather that is dirty. If you wipe softly, the dirt will come off. Then put the bird in an open basket partly filled with hay or soft straw, and place it in the sun or before the fire, according to the time of year. Your pullet lacks the material for forming shell. Supply the runs with bricklayers' rubbish. They will pick out the lime.

Breeding Sebright Bantams (*Mrs. E. W.*).—We are sorry that we can give but little encouragement or hope of success in breeding from a single-combed Sebright Bantam cock. We have bred them largely, and always fancied the single-combed (for such come in all yards) were the best marked and laced birds. We have been tempted sometimes to breed from such an one, but the result only proved that which we knew, yet hoped for an exception, that defects are more certainly transmitted than merits. Doubtless the parents of your bird were correct in every way, and it is probable the majority of his progeny would be equally so; but he has thrown back to some great grandfather or grandmother, and so surely as he has inherited, so would he transmit. We cannot understand why the chickens should die if the hens are kept under the rips, and the chickens are treated as we advise. We believe that the survivors will be as hearty as may be desired. We shall be glad to hear. Why not send us "Annals of my Poultry-yard?" you can well tell about what you like so well.

English and African Owls (*A Regular Subscriber*).—There is a similar difference between English and African Owl Pigeons as between common Tumblers and Shortfaces. The English Owls are large, fine, strong birds, and birds of flight; their colour usually powder blue or silver. The African Owls, on the contrary, are very diminutive, delicate-looking, and tender birds, and their fit place an aviary, which must be warm in winter; in short, they are exquisite little toys. Their colour is frequently a pure soft white. A true-bred pair should weigh less than a pound.

Middleton Poultry Show.—We are informed that the first prize for Black Hamburgh cockerels was not awarded to Messrs. Mason & Walker, but to Mr. Charles Sidgwick, Ryddlesden Hall, Keighley.

Rabbits at Whitby (*One who was Present*).—You are quite mistaken; the communication is from one who thoroughly understands the subject, and he was not an exhibitor. The Committee, no doubt, were anxious to do right.

Uniting Bees (*T. O. J.*).—A full description of the mode of uniting bees by fumigation will be found in "Taylor's Bee-keeper's Manual." As it occupies eight pages of that work, and may, moreover, be now regarded as an obsolete process, it would take up too much space to transfer it to our columns. It is best done in the evening after dark, but we should much prefer operating in the morning by driving, as advised in page 218.

Honey as Bee Food (*W. S. F.*).—If you add a little water to your otherwise useless dirty honey, and then scald it, you will render it perfectly available as bee food.

Dogs' Meat (*R. B. Bart*).—Our correspondent did not require the information you have obligingly sent. He has a large amount of animal offal to sell.

Food for a Cow (*Inquirer*).—When grass has been deficient, as it was during the greater part of the summer of 1868, we gave our cows hay in the yards night and morning, alternating with oil cake and brewers' grains, the grains as well as the bran mashes increasing the quantity of milk at the expense of quality, as is well known to all engaged in supplying milk for sale. Where the best quality of milk is wanted, hay, grass, and only linseed cake ought to be used; and be careful no hot-seeded cake finds its way amongst the latter. A small quantity of Swede turnips may be given further on; and in March, mangold wurtzel may scarcely be detected, but do not give it earlier than that. On no account give cabbage or white turnips; potatoes, however, may be supplied if you have them, but latterly they have been too dear for the purpose.

Cow-droppings on a Pasture Field (*Idem*).—To pick up these will deprive the field of the manure, which acts as some compensation for its supplying the herbage the cattle consume, and although the spots where the dung falls may appear to produce for a time coarse rank grass which the cow may seem to dislike, yet if you wait till autumn or winter you will find that most of these rough places disappear, and they form an excellent reserve for that period, but you might spread these droppings as soon as they are dry enough. To expect animals to graze evenly over a given space all at once as the scythe would make it, is out of the question, the finest pastures being seldom found so excepting where overstocked and, consequently, very bare.

Goat Keeping (*X.*).—A Goat would not annoy you by bleating; but at times she would be dry, and then you must resume the "sky blue." She must have a male companion occasionally; and there is some knack in milking.

POULTRY MARKET.—October 6.

Our markets are dull, and quotations to be depended upon are almost impossible. The close, hot weather renders immediate sales necessary, and they cause great variations in price. Many of the Pheasants that have come in were forward birds.

From observations taken near London during the last forty-two years, the average day temperature of the week is 59.3°; and its night temperature 40.4°. The greatest heat was 80°, on the 14th, 1861; and the lowest cold 24°, on the 15th, 1860. The greatest fall of rain was 1.04 inch.

THE GLADIOLUS.—No. 3.

IT was a great misfortune, that, just as the Gladiolus was coming into more general favour, and amateurs were taking up its culture, the Crystal Palace Autumn Show should have been discontinued, the only place now where it is shown in London being at one of the Tuesday Meetings of the Royal Horticultural Society. I tried to get up a special international show at the Palace. The Directors behaved with their usual liberality, but I did not think that the amount of support offered warranted me in taking their money, and risking an indifferent exhibition afterwards; for there was no certainty as to the French growers sending collections over, without which it could not be international.

The prizes offered at Kensington were very small, not sufficient to pay the travelling expenses of those who gained them, while the arrangements were bad, but upon a remonstrance being made, and the defects, unavoidable at the time, pointed out, we were promised better accommodation in future. However, it afforded an opportunity for a few of us who were interested in the flower, and who had fought for it through evil report and good report, to compare our experience, and suggest methods of overcoming the difficulties that beset its growth, and it is of these I would desire to say something now.

All growers of the Gladiolus know that it is subject to a mysterious disease, under the influence of which the bulbs become spotted, and then perish. What is the cause, and what the remedy for this? are then questions of great importance; and next to these arises another—Can any method of culture insure its non-appearance? I am sorry to say that very little of a really satisfactory nature was elicited. In my own experience it has happened that my entire collection perished; the method of culture had not been altered, the character of the ground was the same, yet three years ago I had hardly a Gladiolus left. All who met and talked together, had to tell more or less of similar losses, although not perhaps to the same extent. Thus, Mr. Kelway stated that last year he had 50,000 bulbs, and hardly one of them was affected, while this year disease was very prevalent. Mr. Sladden, of Ash, a very large amateur grower, has a considerable proportion of diseased bulbs. Messrs. Bunyard & Son, of Ashford, spoke of it as very discouraging, my own experience tending to the same result—that this year was much more injurious to them than last. Nothing could be better than the appearance of the grass as the bulbs speared above the ground, and until it was 5 or 6 inches high, and then many of the plants turned yellow. It would appear that, no matter what was the method of cultivation and the character of the soil, this occurred. I am therefore inclined to think we must look for the cause in the bulb itself. We have to recollect that the Gladiolnses are originally natives of South Africa, and although Natal be temperate, yet we cannot expect the productions of the country to be quite calculated to bear the vicissitudes of our climate; and then they have been so extensively bred in-and-in that a degree of delicacy of constitution has been thereby engendered. Now, a year like the present, when we had a forcing sun and mild weather in the early part of the season, succeeded by the long-continuance of cold north-easterly winds in May and June, must seriously have told on their well-being. Last year we had nothing of this kind, and as a rule I believe the growth was more healthy, but the great lack of rain must, I think, have told injuriously in some places—it did certainly with M. Souchet, whose bloom was the worst he had had for some years. A favourable season for the Gladiolus, I consider to be a moderately cool summer (not cold), with copious rains at intervals.

As to soil, I believe that M. Souchet's idea is that a good kitchen-garden soil is that best suited for them. I this year have adopted a plan, which I believe I have already mentioned, that recommended for the Persian Ranunculus—viz., to take out the soil to the depth of a foot or more, place a layer of cow dung about 5 or 6 inches thick, and then replace the soil. Let this be done in the autumn, and when the bulbs are planted they do not come in contact with any manure, but when the roots push they get down into the cool cow dung, and draw their nourishment from it, and I think flourish accordingly. With regard to taking up the bulbs, it is by no means necessary to wait until the grass becomes quite yellow, but when there is fear of early frost, or of the ground becoming very soddened, it is desirable to take them up. If, in doing so, any of the bulbs are found much spotted, my advice would be to let them dry a little, and then replant them. Selecting a convenient spot in the garden, prepare the ground, put in plenty of sand, and see what the result will be: for I am convinced that those much affected, when stored away, gradually become worse, until the corm withers up completely, and becomes quite black; it cannot be worse if planted, and my idea is it would be better.

And so ends my chat for this season on the Gladiolus, both at home and abroad. I have been more than ever charmed with the flower, and wish that I could awaken an interest in it in others at the same time. I have not hesitated to state that there are difficulties and discouragements connected with its growth, but they are not sufficient to outweigh the pleasure and delight it gives.—D., *Deal.*

PREVENTING GRUBS DESTROYING CABBAGE PLANTS.

There appears to be an exceptionally severe havoc made by grubs on the Cabbage plants this season, and the chances are that you kill the plant rather than the enemy by appliances, as noticed in your Journal of last week but one. The plants in the seed bed are comparatively unmolested, and the reason is that the grubs feed near the level of the soil's surface on anything that suits their taste. Evidently the woody substance of the plant level with the ground in the seed bed does not suit them; but as soon as you put the Cabbage-plant stems down

2 or 3 inches below the surface in planting them out, exposing the tender part—the collar—to a level with the surface, they are at once attacked and nipped off by the enemy.

If your readers avoid inserting the plants so deeply as is usually done the grubs will seldom interfere with them; and if a slight furrow be made, say the depth that the plants stand extra out of the ground, they will be little the worse for the shallow planting.—J. W.

[We hope some will try this simple plan, which seems reasonable.—Eds.]

MEMORIAL TO MR. JAMES VEITCH.

Mr. James Veitch has passed from amongst us; not so the fruits of his labours, they remain to give pleasure to all who have any taste for what is beautiful in nature. If it is true that the man who makes two blades of grass grow where one grew before is a benefactor to his race, what shall we say of our deceased friend? Shall we not be grateful? and should we not take some means to show it?—a monument over his grave, or a fund from which in all time coming an annual award could be given to anyone who made the most important addition to the vegetable productions of our land, either by new introductions, or hybridisation. Think and talk over this. There are plenty ready to aid any effort you "head centres" may set on foot. I have had letters about this subject, and I believe there is a wide feeling about it.—W. Thomson, *The Gardens, Dalkeith Park.*

[Heartily will we aid in promoting the acquirement of a fund to be invested in the names of trustees, and the interest to be awarded yearly in the form of a medal to the importer or raiser of new plants who may be considered most deserving of the honour. It should be named The Veitch Medal; and awarded as it would be to residents in various countries, it would be, like the plants Mr. Veitch has introduced, an annual, honourable, and enduring memorial of him in many lands.—Eds.]

GLOIRE DE DIJON AND MARÉCHAL NIEL ROSES.

In thinking and writing about these two fine varieties one is tempted to paraphrase a well-known passage, "Sure such a pair was never seen." For some weeks past I have had almost daily under my eye a square containing about a thousand plants of the first-named sort, full of flowers, and filling the air with their delicious perfume. They are budded close to the ground on Manetti stocks growing in a stiff clayey loam. Their vigorous growth is remarkable, as most of them are from 4 to 5 feet in height, each stout stem as thick as one's finger, forming a sort of pyramid of flowers issuing from the young side branches. It is curious to observe the contrast of this sort with other kinds of Tea Roses budded on the same kind of stock and in the same square, for they have to a certain extent not done well, many buds having failed; and those that have succeeded, even the vigorous Climbing Devoniensis, have made but a feeble growth comparatively. Why the Gloire de Dijon Rose should succeed so well on the Manetti stock is one of those small yet interesting mysteries so often found in practical horticulture, and which the *savans* seem not to be able to account for. Some hundreds of the Roses I have just described were budded in August with the Tea Rose Maréchal Niel. This kind of "double working," to use the gardener's phrase, *alias* double-budding, on the Gloire de Dijon Rose, was, I think, made public to the Rose world by my son a few years since, and has brought about, and will bring about, a complete revolution in the culture of Tea Roses, more particularly in that of the most glorious of all of them, Maréchal Niel. It is quite true that this sort will grow and bloom well when budded on the Dog Rose (Rosa canina), but it is not so lasting, and never is it so completely at home as when budded on the Gloire de Dijon. It even seems more than happy, and rejoices its cultivator by giving grand leaves, grand shoots, and more than grand flowers in abundance from end to end of the Tea Rose season, which may be reckoned from the end of February till the end of October—earlier and later at the will of the clever cultivator.

It is really a curious and most interesting physiological question, why the Gloire de Dijon Rose should succeed so perfectly when budded on the Manetti Rose, while other kinds of Tea Roses with habits nearly as robust should fail or make but feeble growth. There are many anomalies in practical horticulture which the closet physiologist in vain attempts to solve, and which never will be solved till we get a Darwin and confine him in a large nursery garden for some two or three score years.

Apropos of the change which soil often makes in vegetable growth. Some years ago, a friend living in the red-soil district of Devonshire planted some Pear trees grafted on the Louise Bonne Pear grafted on the Quince on my special recommendation that no kind of Pear could do better on that stock, and that grafted on the Pear stock it bore fruit of inferior quality. A few years after this period he wrote me that his Louise Bonne Pear trees on the Quince stock had cankered, and were in a diseased and dying state, while those which he happened to have on Pear stocks were doing well and bearing fine fruit. This fact has come to my mind on observing in your pages one or two correspondents complaining that Roses on the Manetti stock do not do well with them. Now, although Roses on that stock flourish here in all descriptions of soils, whether stiff clay, loam, or sand, it is quite possible they may fail in some few—very few—places; it may be in the cool moist climates of the north, or where there is an absence of chalk or lime in the soil: one cannot tell. At any rate, dwarf Roses are now so cheap that a trial can be made without much outlay. It is to me half amusing to read about such things after the stock has been fully tried for nearly forty years. I had at one time fierce battles with the Messrs. Paul and a host of others, but they have for many years rested on their oars, and have settled down to earnest cultivators of the Manetti stock. Your correspondents need not think that Rose-growers have taken to the Manetti stock as a measure of economy. Dwarf stocks of the Dog Rose are bought at 20*s.* per 1000, while those of the Manetti cost more than double that sum if they are good and well selected.

I ought here to mention a fact not generally known, that Moss Roses of all kinds, even the White Moss, make as healthy and more vigorous plants when budded on the Manetti as on their own roots; they should, as usual, be planted so as to cover the junction of the bud with the stock. It is the same with the varieties of Rosa gallica, now things that have passed away.

I feel that I ought to point out a great advantage which the use of the Manetti Rose stock gives. In old exhausted gardens, in which Roses on the Dog Rose barely exist, and in which manure seems to have lost its stimulating effect, the Manetti Rose will flourish, and even make a most vigorous growth if the soil is stirred to 2 feet in depth. I say this with confidence, because I have found it do so here in soils in which Roses on the Dog-Rose stock have been grown for forty years in rotation, till at last they have ceased to show any vigour, and merely exist. In such soils, treated as above, Roses on the Manetti stock give great pleasure to the amateur by their luxuriant growth, seeming to make an old Rose garden young.—T. Rivers.

GOLDEN CHAMPION GRAPE—INFLUENCE OF STOCK.

I notice in the Journal of September 23rd, Mr. Record's comments on, and experience of, Golden Champion Grape. My own experience has been somewhat different. My first acquaintance with this Vine was in the form of young plants at the nursery of the Messrs. Osborn, of Fulham, in May, 1868. They had one house full of young plants in various stages of growth, and as fine a lot they were as any one could desire to see. I set it down directly as a strong grower on its own roots, and ordered a plant, which I received about the 1st of August; it was shifted into a larger-sized pot, and inarched on a young plant of Black Hamburgh. It did not grow much that season, but this year it has run up a 10-feet rafter, and would have gone further if it had not been stopped. The young plant on its own roots made two very strong shoots in the spring, when one of them was inarched on a Hamburgh, and the other on a Trentham Black. It does not seem to take well on the Trentham, but we must wait another year until a correct opinion can be formed of it.

A correspondent in a contemporary has strong doubts of the stock having any influence on the scion in grafting the Potato; it has in the case of the Grape Vine. Mrs. Pince's Black Muscat grafted on Lady Downe's, is quite changed in appearance, and also in flavour; it does not look at all like the same variety on its own roots, and as far as one would judge from appearance at the present time, Golden Champion on Trentham

Black will be different from the same variety on Black Hamburgh. As to the appearance and quality of the fruit, I have seen it at exhibitions, at Dalkeith, in 1868, and also in the present year, but have only found one mark to note against it, and that is, when the fruit is quite ripe, some of the berries are affected with brown spots, which seem to be more than skin deep. This is accounted for by the exceedingly thin skin of the berries being easily injured by sulphur fumes, or water incautiously sprinkled on the hot water-pipes. In a young state it is said to be shy in showing fruit. I found the laterals where it was pinched back, showed bunches during the summer, so I have no doubt it will fruit well next year.—James Douglas.

AUTUMN CROCUSES.

Your correspondent, "M. H., *Acklam Hall*," deplores the loss, or the supposed loss, of many of our autumn-flowering Crocuses. Now, with regard to one of the most beautiful—viz., Crocus speciosus, I think that if he could visit the establishment of the Messrs. Osborn, at Fulham, he would find a splendid patch of this variety, which has been during the last week "glorious;" indeed, it seems to be naturalised there, for it is to be seen coming up even in the gravel walks.—F. J. S. H., *Fulham.*

A VISIT TO A LINCOLNSHIRE PARSONAGE.

The occasional communications contributed from time to time to the columns of the Journal by "C. C. E.," including the pertinent query "Who is to blame?" which would seem in some degree to have disturbed the equanimity of the horticultural world, may have—at least in a few isolated cases—given rise to another very natural query—Who, what, and where is the owner of the three familiar letters? An answer to this supposed query may not be altogether uninteresting at this juncture. Now, as to the "who," I have no warrant to add some other alphabeticals which to me seem to come very naturally after the "E.," so will content myself by saying that he is a member of a family of considerable standing and influence; that he is a clergyman, and—yea—a gardener; and that on a clear day the towers of Lincoln's glorious minster may be seen from his garden; and to make it a little clearer still, I may say that these towers may be seen for upwards of twenty miles round. So much for the who, what, and where.

Horticulture in its different aspects owes much to the resident clergy of this country. It would seem to be a study particularly congenial to educated minds. Alluring, comprehensive, interesting, and gratifying, what wonder, when such minds imbibe a foretaste of its genial influences, they should press on to the health-giving fountain with zeal and enthusiasm. Such energy, such enthusiasm, intelligently exercised will and must ensure success. And who cannot but recognise the ability, the willingness, nay, almost the anxiety, of those gentlemen to communicate through the qualified channels to others the recreation and enjoyment which they themselves have so freely partaken of? And, on the other hand, who stands forward more boldly, and breaks through the cordon of trade interest, and proclaims more loudly, not what pleases, but what disappoints them—a voice of warning which they feel called on to give for the benefit of their co-workers, and for the real promotion of horticultural progress? Into this army of clerical horticulturists is now fairly enrolled "C. C. E."—a worthy member of a worthy band, who, as time rolls on, will occasionally step into the front rank with a budget of information, sound, because matured and practical, the result of careful and systematic observation.

Up to the present time "C. C. E." has confined his gardening exercises to hardy fruit culture especially, and to vegetable culture incidentally. Having become fairly established in these branches, he is now desirous to emulate his compeers in another branch—Roses. To this end he has purchased additional land adjoining his garden. His garden—we will now look into it, or more particularly into a part of it, for it is in two divisions, the old and new. The latter is the plot most interesting. In size this portion may be two or three acres, and in form for practical purposes may be called square. A few years ago—five or six—this was an old ridge-and-furrow grass field of but a very ordinary character. What a change! "C. C. E." has commenced work in the spirit of the old proverbs, "What is worth doing at all is worth doing well," and "Well done twice done." He was not only studious to carry stagnant water out of the garden, but equally so to carry fresh water in. He has drainage in and out. Here Nature was his handmaid, and he was quick to turn her services to account. Situated on the western declivity of a range of hills, it occurred to him that simply holding up the watercourse a given height—it runs past his garden—would give him a reservoir of supply quite under command. "C. C. E." is not only fertile in conception but decisive in action. The thing was done. Supplementary reservoirs are formed in different parts of the garden; these are placed at the proper level, and are in pipe communication with the reservoir proper. By the simple use of a sluice and plugs, he has water in or out at will. From these reservoirs an engine will throw water in all directions. An excellent idea well carried out.

The water in subjection, his battle is now with the winds. The garden is intended solely as a fruit garden, and it is fully exposed to the full sweep of the north and east winds. To break their force, not a wall but an embankment is run along the entire north and east sides. This is not a mere hillock thrown up of any sort of material at hand, but is a work of some magnitude formed of splendid maiden soil. It might be appropriately designated a railway embankment, for, by a happy synchronism, at the time "C. C. E." was making his garden the Great Northern Railway Company were making a railway contiguous, and as the soil wanted taking out of the one and putting into the other, "C. C. E." was wide awake, and quickly on the spot stipulating for the top spit of the railway—an old pasture soil, a medium hazel loam. This is the soil of the embankment. It is quite filled with hardy shrubs, which, as may be supposed, have grown remarkably well. At regular intervals, especially along the eastern side which slopes to the walk, are planted choice and hardy kinds of Coniferæ. The block is already effectual, and is and will be highly ornamental. The shrubs on the south slope of the north embankment do not reach down to the walks, but a border is left containing six rows of pyramid Pears and Plums running parallel therewith.

The level or general soil of the garden largely consists of this imported loam. I am afraid to say how many hundred loads have been appropriated. The whole is trenched over and intermixed with well-rotted manure and crushed bones in no homœopathic doses. This is something like beginning to garden. The eastern boundary to the garden is a large hedge which thus separates it from the old garden and vicarage house. A hedge also forms the boundary to the south. The entrance to the garden is at the north-west corner. The garden is intersected by three main grass walks 5 feet in width. The turf of these walks is in the finest possible order, and as level as a river. They converge at the point of entrance on a small plateau of lawn. One walk branches off in a southerly direction and parallel with the eastern boundary fence, leaving, however, a border about 20 feet wide between the walk and fence. Another takes an easterly course, parallel and a short distance from the foot of the north embankment, and the third or main walk strikes straight across to the opposite or south-east corner. At the end of this long walk is a veritable earth-work on which are fixed the targets for rifle and archery practice, in both of which "C. C. E." is no mean adept. On each side of these walks runs a row of Strawberries, backed-up by rows of fruit trees, bush and pyramid, of Apples, Pears, and Plums, the dwarfest in the front, the tallest at the back, and the trees in each row of the same height and size.

There are, of course, other walks of ashes for the convenience of working operations. I have seen "C. C. E.'s" garden under different aspects, but to stand at the entrance in the middle of April and look down the straight long lines of blossom which radiate in all directions, is a sight worth going far to see.

The trees, as before remarked, are planted parallel with the walks, in rows of from three to six. They are planted thickly, so that half of them will be thinned out and planted in the angles which are thus formed by the peculiar arrangements of the walks. The garden will be eventually a fruit garden solely, but in the meantime these angles are devoted to the culture of vegetables, and such vegetables! they must not only be as fine, but finer than other people's to satisfy. Here I saw the veritable Supreme Pea, which grew such a length that it got quite out of the garden into the post office, and we all know the result. When I saw the Pea it was 3 feet high, and had not begun to blossom. I think we may fairly allow any Pea to grow a few inches above its orthodox height in such a garden as this, but it certainly should not have overgrown and smothered the row of Veitch's Perfection by its side. I have seen this Pea

in many gardens, and the opinion is prevalent that "C. C. E.'s" complaint is real; still all say it is a fine Pea, and all say, and this includes "C. C. E.," that they will grow it again. Such is my experience, which I may here parenthetically record. The vendors' mistake was in accepting the result of the hot early summer of 1868 as their sole guide.

Of the other, or old garden, it must suffice to say that it may be about an acre, and it contains numbers of fruit trees, a little lawn, choice shrubs, and an apiary, and, like every other part of the grounds, is in first-rate order. If I recollect rightly, the total number of trees in this interesting garden is close on 2000, and the varieties 250. All are healthy, and many of them bearing splendid crops of fruit. I saw a fine line of Lord Burghley Apples, some of them with a few fruit on, also Mr. Gladstone, not in a fruiting state. Some bushes of Cox's Orange Pippin were magnificent; and amongst Pears, Beurré Diel, Beurré Superfin, and Louise Bonne of Jersey, were very attractive.

"C. C. E." has a few vertical cordon Peach trees which he does not like, and a few diagonal cordon Pears which he does like. Bush and pyramidal trees are his forte; he knows, or shortly will know, all about these. Pruning in different ways tried, and effects carefully noted, manures the same, time of blooming and every peculiarity observed for future guidance, he will thus acquire a mass of information of much value; and not alone for himself, but for all who care to know, I am sure he will care to tell his experience. Of flowers, there is nothing remarkable except a plant of Pampas Grass with upwards of sixty noble spikes of inflorescence.

Before taking leave of the garden I must not omit to notice how extremely creditable the whole place is to "C. C. E.'s" active man Bentley. Bentley thinks much of his garden and much of his master, and herein is the secret of success.

I will just for one moment step out of the garden into the workshop. Here order prevails—a splendid lathe, tools of all kinds, and all used, for in this line "C. C. E." is justly celebrated. He must verily inherit the spirit of Lord Brougham when he exclaimed, "If I had been born a shoeblack I should not have been satisfied until I was the best shoeblack in England." Here, too, were arranged volumes of the Journal, and everything at hand for a man of business. In the village are to be seen fine new schools just erected, the result of his energy. Altogether I am much pleased with this place, and with nothing more than the kind and hospitable manner with which I, a plain working gardener, am entertained on my occasional visits, except it was the advantage I recently had of hearing him from his place in the sacred edifice adjoining—in this as in every undertaking earnest—deliver a powerful extemporaneous discourse from a text always applicable to all persons, under all circumstances, at all times, and here it is: "What I say unto you I say unto all—Watch!"—J. W.

ENGLISH-SAVED STOCK SEED.

Through the kindness of Mr. Dean, of Ealing, I have been enabled to give the above a good trial along with other kinds of Stocks, including the East Lothian. They were sown about the middle of April, and treated in every respect the same as imported seed, but the difference of the plants in vigour of growth and continuance of flowering was remarkable—so much so, that some of the individual spikes that were exhibited at a local flower show were pronounced by the judges to have been those of the Large-flowered Brompton. One kind that attracted much attention was of a canary colour, the plant producing four or five large trusses of very lasting bloom; another was prettily mottled and shaded with light blue, being undoubtedly quite new in colour. The habit of the plant was the same as in the preceding kind. These two partake of the character of the large-flowering German Ten-week, but are very much superior.

The Pyramidal Large-flowering scarlet, purple, and white Stocks were very fine, some of the flowers being as large as those of the Brompton, but coming into bloom at the same time as the varieties previously referred to, and should the weather continue mild they will flower until Christmas. A white variety which was a few weeks later in blooming is now very fine, being somewhat like the White East Lothian, but of more compact growth, and it will be fine to succeed that variety.

I will add that all the kinds produced a good proportion of double flowers, but not quite cent. per cent., as stated in your number of August 19th respecting the East Lothian Stocks, though unquestionably they are valuable introductions, and will be very generally cultivated. They are still very fine with me, producing about 80 per cent. of double flowers, and of this proportion I think no person could reasonably complain.—E. Welsh, *Palace Gardens, Armagh.*

WELLINGTONIA GIGANTEA.

[A correspondent, in reply to Mr. Robson's inquiry in page 168, respecting the Wellingtonia, has written to us under the signature of "The Master Gardener," that he has several trees of this species measuring respectively 20, 23, 24, 27, 29, and 32 feet in height, the head of the last-named tree covering a space 26 feet in diameter. The whole of them are in perfect health, without any of the appearances of premature decay, as described by Mr. Robson. "The Master Gardener" also justly asks if a tree 32 feet high and 26 in diameter is not one of unusual size? He mentions, however, having seen at other places much smaller trees in an unhealthy condition, which he attributes to the dryness of the season. He likewise states he has Cryptomeria Lobbii 26 feet high, and justly enough regards it as a very fine tree, although it has latterly formed four leaders, which he thinks check its growth, and he would like to know what to do with them. He also asks if slightly digging with a fork over the roots of Conifers is likely to do harm, as he has hundreds of fine specimens, and the appearance of the beds they are growing in is of much consequence. We forwarded our correspondent's letter to Mr. Robson, and append his reply, hoping also to hear again from "The Master Gardener" on the Wellingtonia and other Conifers, of which he has such fine specimens.—Eds.]

The specimen of Wellingtonia 32 feet high, and 26 feet in diameter of head, is certainly one of the finest, if not the very finest, in the country; and I am glad that neither it nor the other large ones mentioned show any sign of debility, which I had heard of elsewhere, and in one case seen here. I therefore hope the cases where a premature decay has set in may be traced to some local cause, for which there may be a remedy. I trust, nevertheless, that your correspondent will describe more fully the character of the soil and situation his trees are growing in, and give every needful information, as it is quite possible many of us may have planted the Wellingtonia in unsuitable situations; and although it may flourish for a time, yet in the course of a few years it falls a victim to some latent disease, which, like consumption, carries off the subject after he has enjoyed a few years of more robust health than that often accorded to individuals destined for a more prolonged existence. Whether this be so or not remains to be proved by those who planted the tree soon after its introduction to this country, or, in fact, who have the largest specimens. In this county (Kent), Messrs. Hollingworth, of Turkey Mills, near Maidstone, have in their grounds some very fine trees, about 28 feet high, and I believe in the garden of the High Sheriff, Mr. Ridgway, at Fairlawn, there is a specimen 30 feet high, which a few years ago I knew to be a remarkably fine tree, one similar to the last being in the garden at Redleaf, where, as well as at Fairlawn, are some excellent examples of ornamental trees and shrubs. It would be a great boon to intending planters if more particulars about this remarkable tree were published.

The Cryptomeria Lobbii mentioned by "The Master Gardener," is also a fine plant; but the difference between it and C. japonica is so very slight, if any, that the tree is possibly one of the latter species which was introduced some years before that named after the enterprising traveller Lobb. There are many fine trees of C. japonica in the country. One that was growing in the grounds here (Linton Park) was upwards of 41 feet high, when it was broken asunder by a high wind in February, 1867; it was as straight as an arrow, and although close-growing, its spread was hardly more than 8 feet in diameter anywhere, being a perfect spire. The plants of C. Lobbii here seem so determined to produce seed vessels, that their growth is certainly impeded.

I would advise that from the tree with four leaders all of these should be removed but one, but do not cut them back too closely to the stem or origin; and if not cut immediately, do not cut them at all, but bend them back and tie them in to the stem they came from; I mean the tips of the leaders. It is better to do this than cut them at any season except August, as most Conifers bleed so much, and tying-back effectually stops competition with the proper leader.

The less the ground is meddled with around Conifers the better, and this applies especially to the Wellingtonia, which produces roots close to the surface, as do many of the Spruce and Silver Fir class. Perhaps Cupressus roots go deeper, C. Lambertiana being often tap-rooted, and if so, it is the better for the tree, which is then supported against the wind, and it may suffer less than others, but I recommend as little stirring of the soil as possible, for I have seen more than one death from that cause.

Since writing the above, the article of Mr. Mayo, from Shalstone, has appeared in this Journal (page 221), stating that he has a fine tree 20 feet high, of corresponding spread of branches, and perfectly healthy and vigorous. I can only repeat what I have said before, that I am very glad of this, and hope the number of those who have to report a contrary state of things may be few, and such as not to affect the general good character of the tree. Nevertheless, if there be any such, it is quite as important (if not more so) to hear of their disasters as to be told of others' successes. As there is always more pleasure in reporting a favourable state of things than the contrary, those who have been unfortunate are entitled to the greater share of credit when they boldly state their case. They afford quite as much, if not more, useful information to the public at large by doing so. The specimens alluded to as being 20 feet high may, perhaps, not have yet reached the point at which disease sets in. We have a fine tree here about that height, with clusters of cones upon it, while others much higher do not show any signs of bearing. For their not doing so I am not sorry, as it must impair their growth.

The specimen of Cupressus Lambertiana, 39 feet high, and with a spread of 30 feet in diameter, mentioned by Mr. Mayo, is certainly a fine tree, and exceeds one of the same kind here, although in point of height the two are about the same; but the tree here suffered severely from the frost of January, 1867. Before that time it was so densely clothed with foliage, that in walking round the eye could not detect, without the hand holding some of the branches, a twig thicker than a pencil; it has partly recovered, but is far from being so fine-looking a tree as it was before that time. A Pinus insignis near it also suffered in a similar manner, but has since recovered, while another tree of the same species, about 60 feet high, a little way off, escaped unhurt; and an Araucaria brasiliensis, not often met with out of doors, also escaped that winter with no more injury than is experienced in other years. It is not, however, an out-door tree, and is far from being happy-looking.

In conclusion, I again invite reports on the well or ill-doing of the Wellingtonia from all quarters, especially where the trees have been planted ten years or more.—J. Robson.

FORCING PLANTS.—No. 2.

But few having houses specially set apart for forcing, and the plants to be forced having to be grown and flowered along with other plants, it will be necessary to make a few observations on this subject. A cool greenhouse with a night temperature not exceeding 40°, is a good place for the majority of hardy shrubs and plants, for the first three weeks or month of their being taken under glass for forcing. For at least a fortnight they ought not to have a higher temperature, but be slowly excited into growth, and then they may safely be placed in greater heat—say in a warm greenhouse or cool stove, giving them when first introduced the coolest part of the house, and a position well exposed to light and air, and removing them to a warmer part as they advance in growth. They ought never to have a temperature exceeding 55° at night, and for most plants 50° at night will be sufficient to bloom them strongly and well.

Persons having vineries where forcing is commenced in January, and where other houses are started at monthly intervals, will not have much difficulty in forcing plants. All hardy shrubs or plants succeed with the treatment given Vines in forcing. The heat is low to begin with, abundance of air and a moist atmosphere are afforded, and the temperature being progressive, is well suited to them, as they, for the most part, flower before the temperature is so high as to draw them up, or the shade of the Vines becomes so great as to deprive them of the light needful to become strong, well-flowered plants. The plants should have positions near the glass, and if the houses are lean-to's, or the light stronger from one point than another, the plants should be frequently turned round to keep them from becoming one-sided.

Peach houses, too, are excellent for forcing hardy plants and shrubs. If these be placed in the house when forcing is commenced, they will flower even better than those in a vinery, from the greater ventilation and lower temperature of the Peach house.

Plants for forcing should be of the best possible description—stiff, strong, compact, well-grown plants, with the growth of the previous year well matured, well set with bloom-buds, or if herbaceous plants having the crowns or buds plump and round, not narrow and pointed; and they ought to be established in pots at least one year, or so recently transplanted that they may early in autumn, or at the end of summer, be moved with good balls, and potted without depriving them of more fibres than can well be avoided. Evergreens are best potted in September, if the growths are mature and the buds fully developed. They should be well attended to with water, and the pots plunged in coal ashes in a warm, sheltered situation. Deciduous shrubs ought not to be removed until the leaves turn yellow and begin to fall; then the sooner they are potted the better, placing them in a sunny situation, and giving a good watering to settle the soil about the roots. Both deciduous and evergreen shrubs will thus be better prepared for growth and blooming than if taken up, potted, and placed at once in the forcing house.

In November, before severe weather, they ought to be taken under glass, especially the evergreens, placing them in a cool, airy, and dry house, such as an orchard house, or unheated vinery. There the evergreens should remain, with no more water than is sufficient to keep the soil moist and the foliage fresh, whilst the deciduous shrubs may be kept dry rather than wet, always taking care not to allow the wood to shrivel from dryness, or the buds to shrink. In severe weather the pots should have some dry hay or litter placed round them. From this house they could be drafted into the forcing house at intervals, not moving them, however, when frozen, for the less they are handled at such times the better, and if they must be moved, let them be slowly thawed, by placing them in the next coolest place to that from which they were taken.

If there are not cool houses, or cold pits, which answer nearly as well as houses, much may be done by placing the plants under the shelter of a wall, plunging the pots in ashes of spent tan, and in severe weather protecting them with mats or other materials; and though such means are but a poor substitute for glass, it is far better than allowing in severe weather the roots to be frozen, and the tops to remain unprotected from snow and frost. It was formerly thought advisable to expose Vines to frost in winter, but the practice is now obsolete, and so it will be in a short time with forcing plants. Severe weather does no good to plants intended for forcing, and though growth may be rapid after the exposure, the sudden transition is not generally followed by a continued vigour of growth to the flowering period.

It is almost superfluous to state that the earlier forcing is commenced the worse the plants will flower, and the slower they are forwarded, particularly in the early stages of the forcing, the greater will be the chance of success. The plants ought to be placed in a cool house for a fortnight, then in a house with a temperature of from 40° to 45° from fire heat, and then in one of from 45° to 50°; and if they are not then in flower, or will not be within another week or fortnight, they may be placed in a night temperature of 55°, which is sufficient forcing for every kind of hardy plant. A fortnight should be allowed the plants in each of the temperatures mentioned. In the cool house they should be kept rather dry, but when placed where fire heat is applied, they should be lightly sprinkled overhead with water twice a-day, morning and evening, and the floors, walls, and other surfaces sprinkled with water twice or thrice a-day, in order to secure a moist atmosphere. The water should be of the same temperature as the house, and sprinkling the plants should be continued until the flower buds show colour and are about half developed, but the floors, &c., should be sprinkled until the plants are in flower, when they ought to be moved to a cooler and drier house, as condensed moisture is apt to discolour them. A house with a temperature of from 45° to 50° at night is most suitable.

Air should be given freely, but not so as to suddenly lower the temperature, for the leaves being grown in heat are more susceptible of cold than when they are formed in the open air. The more air the plants receive, the less liable they will be to become drawn up, and a little air at night improves their health and vigour, as well as the colour of the foliage. In frosty weather little air will be needed, whilst in mild and dull weather it should be freely given, as the plants then grow more

rapidly, and without air are apt to make weak foliage. There should be a change of air at least once a-day. In dull weather less moisture will be required than when the weather is bright, and the ventilation ought at all times to be so regulated that it will not suddenly cool or dry the atmosphere.

The plants when forcing is commenced will need but little water. It will be enough to keep the soil moist until they are growing freely; the amount should then be increased with the growth, but never give water until the soil in the pots become dry, yet not so much so as to cause the leaves to flag. Do not saturate the soil by too frequent waterings, and if it become very wet see that the drainage is efficient, and the roots in a healthy state, for without good roots it is not possible to have vigorous growth and bloom. Keep the plants well supplied with water until the blooming is past.

After flowering the plants should be returned to a house having a temperature not more than 5° lower than that in which they have been flowered, and be there continued for a fortnight; then place them in a cooler house or pit, by degrees harden them off, and when danger from frost is over they may be plunged in ashes in an open situation, attending to them with water in dry weather. Some plants after forcing are hardly worth keeping until another year, but others flower well the second year, and others again are best planted out in the borders after they have been hardened-off.

All plants require to be prepared in the previous year for forcing; but this is rarely practised in private gardens, as plants ready for forcing can be purchased so cheaply. Those best established in pots can be obtained in that way, whilst those which can be lifted and potted in autumn, are grown in such quantities that there are always to be had compact plants with good foliage, well set with buds, and which can be taken up with balls of soil. These can be purchased more cheaply of nurserymen than they can be grown by persons only requiring a few. All plants are not suitable for forcing, and to grow them for the purpose, care must be taken of them previously. They should be well grown, healthy, well set with flower buds, and if they are not so, and well rooted likewise, discard them.—G. Abbey.

BICTON.

When visiting Bicton, the seat of Lady Rolle, a short time ago, I saw an account in your Journal of the death of Mr. Veitch, and I could not help being struck with the idea that it was worthy of record, that there was to be seen there that which would be a living monument to his memory for ages to come, in the noble Araucaria avenue which, as far as I am aware, is not equalled in Britain. It contains fifty specimens most judiciously arranged. I was informed that it was planted by Mr. Veitch about thirty years ago, and was under his care for some years when in its infancy. He also had the care of the noble arboretum at the same period, but I regret to observe that a large number of the original specimens are wanting, to the amount, I was informed, of about nine hundred. Lady Rolle, who is a most liberal patron of horticulture, and is ever ready to grant whatever is required, has expressed a wish that the blanks should be filled up. I have, therefore, no doubt but that the plantations will soon be put in a more perfect state.

I could not help observing many relics of the talent and good taste of the late Mr. Glendinning. He designed and planted the arboretum; he also formed the beautiful lake, in the design of which he was most ably assisted by his noble patron. When I saw it there were hundreds of water fowl upon its surface and banks. Although entirely artificial, I was informed that it was in some places 40 feet deep. It forms a most beautiful object from the mansion, and can be seen from many parts of the extensive park, being a grand feature in the landscape.—A. B., *Cudsden, Bucks.*

DESTROYING WORMS.

In answer to your correspondents "J. A." and others, in your number of the 7th inst., you recommend lime water or ammoniacal liquor diluted with six times its volume of water, for the destruction of worms on lawns and in pots, both of which are undoubtedly good; but the lime water is not so effectual as could be wished, and aqueous ammonia cannot be applied sufficiently strong to kill without injuring vegetation, as you justly remark. Ammonia has also the additional drawback of being very volatile, and, therefore, quickly evaporates. A far more effectual agent, and one not only free from the above objections, but possessing the strong recommendation of being acceptable to most plants, will be found in a solution of 4 ozs. of common washing soda, dissolved in one gallon of water, the solution to be applied in the evening with the rose or spout, according as it may be desired to operate upon beds, lawns, or pots. The strength of the solution may be varied from this standard to suit the condition of the plant or plants, according to the tenderness, maturity, or hardiness of growth. A little experimental practice on the part of the operator will soon lead to just conclusions on this and other points. Soda is one of our strongest corrosive poisons, and instantly affects all moist-skinned creatures, such as worms, snails, &c. A few applications will in most cases prove effectual at a very trifling cost.—H. G.

OUR FLOWER SHOWS.

"There is no mistake about the matter, flower shows are becoming great events in our day, something looked forward to in every town and village; yet I would rather, if I dare speak the truth, my man had nothing to do with them. I knew I shall be considered a croaking fellow, far behind this enlightened age."

"So you are in this respect, Harry," replied his brother, "and why, I cannot understand, unless you have been for years an unsuccessful exhibitor."

"No, I have never exhibited; my man has done so by sufferance, it is his hobby; the laurels are all his own when he wins them. I am not sure they are worth the cost—think of the labour and anxiety, the hopes and fears, the strange methods resorted to, to gain the required form and bloom. Ah, Frank, many a gardener looks at his poor thin ducks until in the fever of the excitement up to which he has worked himself, he fancies them swans; and then when the proclamation goes forth they are but ducks, what a downfall, what disappointment and heartache; and worse, unbelief in the fairness of the award!"

"And he is not worth much if he does not go home determined to work and win another day. You speak like an outsider, once within the magic circle your feelings would change, Harry."

"It should be remembered, Frank, the outsiders far outnumber those within the circle. I am not sure my feelings would change under any circumstances, not even if I became, what appears to me an impossibility, one of your favoured few. Our flower shows are something like poultry shows, success runs ever in a groove; it is only by some extraneous effort the old is pushed aside to let in a new element. Then, too, to an idle looker-on, prize-giving appears such an anomaly; bulk often wins the day, the largest bundle of sticks carrying off the first prize. Some monster plant with an unreadable name is sure to have the honour of bearing the white card, and though everybody admires it, or pretends to do so, yet few would have it at a gift. This successful giant travels about from town to town, and from show to show, as long as the blooms remain, then goes home a pitiful object, with its plantation of supports and immeasurable yards of string exposed to view, to be hidden away in a dark corner, nine times out of ten to drop off—a natural result if you will push all energies in one direction, until, however brilliant the success, the chance of life is small. I likewise do not admire the necessary appearance of the plants intended to compete for prizes; Nature is so cut in, rounded off, and tied out, that all perception of what the individual plant should be is lost. Art not Nature, the gardener's skill, not Nature's aided growth, is exhibited, for which I suppose committees hold up their golden prizes. Behind my time, or before my time, I must confess, Frank, I do not admire them, would not have them at a gift, and I ever come home with a thankful feeling I have not to find house-room for them. Why should all life, and grace, and charm, be cut away from them, not even a stray leaf allowed to make light and shade? That Bramble bush clambering over the old stone wall, and spreading forth its leaves and flowers, and wild fruit, has more grace and beauty, and gives more pleasure than the beautiful Stephanotis when dressed out, rounded off, I should rather say, into its tub-like shape."

"You do not know the hours of labour bestowed upon these specimen plants to bring them into a blooming condition fit for exhibiting."

"No, indeed, I do not, Frank—they may be even more than I imagine; but surely that is no reason the plants should be twisted and twined, and tied and tortured, as if roundness were the only form of beauty for which a prize could be given. Why, our forefathers had more variety of shape in clipping their ever-

greens. There is something positively distasteful in the sameness, the uniformity, the repetition one meets with at flower shows. Some plants come over and over again, looking just the same; it needs only a slight stretch of fancy to think the Pelargoniums are the very same plants that stood in the same place the year before, perhaps a little fuller in bloom, or requiring a few more supports, a greater care in management lest the shaky petals should fall away, and the leggy branches be too much revealed. We hear of new varieties, but they come not to our provincial shows, not even as cut blooms, which would be most interesting to many, who have neither money nor time to run up to the great shows of the metropolis. I think Orchids, with their dried bulbs and stems, and ungainly shoots, and speaking flowers, ever resist the gardener's taming process, growing after their own fashion, and retaining even under the highest cultivation, a certain rare wild beauty, which never loses its attraction."

"We could not get up a great show of Orchids alone. I know of old, they drew you against your will to the very shows you abuse."

"Certainly not, Frank," replied his brother, "very undesirable if you could, for it would not pay; it takes a high stage of culture to find real pleasure in gazing upon Orchids, more than the great bulk of visitors to flower shows possess. But you could offer prizes for smaller specimen plants grown in a more natural form, with fewer, nay without any, green-painted sticks —an outrage, as they undoubtedly are, upon good taste and skilled growth, for the best of all work is that where the worker is lost. When hundreds, nay thousands, might come in to compete, poor curates and working doctors like myself have a chance —possessors of small houses and unheated pits, in which the prize-taking monsters would be out of all proportion; and then the poor man-of-all-work, who must tend his mare, and milk his cow, and weed his garden, might possibly after all realise his ambitious hopes and become a prize-taker, without having the pleasant cup of success dashed aside on his return by the sight of neglected work."

"I suppose, Harry, you would make it so easy to win a prize, that everybody could receive one?"

"I would make it a possibility, which at present it is not. I would bring it in many of its arrangements within the reach of busy, hard-working, practical men. There are many such gardeners about small villa residences in the neighbourhood of large towns, possessed of a considerable amount of knowledge and skill, and often fired with a laudable desire to try their luck in prize-taking."

"I do not wonder, Harry, it is the bit of fire that keeps them alive, that breaks the dull monotony of their existence."

"To the danger of striking out a less pleasant kind of fire. All very well if a man has the time and the means, if the thing is not so far beyond his reach but that he may fairly hope to win it; but if a man's hands are full he should not try to grasp more, lest he lose the needful substance reaching out for the pleasant shadow. To me there appears an absurdity in the little dark lean-to, like my own across the garden, competing with a large span-roof all light and air; that is why I had rather my man had nothing to do with flower shows, for all his labour can but end in heartache and disappointment. When committees offer prizes for plants of one or two years' growth, then my creaking may possibly blossom into an enthusiasm even surpassing my gardener's; but I cannot give up my house to large show plants with their detrimental shade over younger and smaller, and yet in my eyes more beautiful plants."

"Well, after all, Harry, I am afraid you would make it too easy to win a prize; you bring down the standard rather than lift up to it."

"I would bring the standard within the reach of the multitude, and so increase the interest, and most certainly, Frank, the returns. It will come to it by-and-by. In flower shows, as in everything, we weary of the old, and look out eagerly for the new."—Maud.

LADY-BIRDS.

I have been greatly troubled with aphis this season, particularly on Melons and Cucumbers. I fumigated to such an extent that the plants succumbed before the fly did, and I considered my case hopeless, and determined to try no more. Having heard of the lady-birds feeding on aphides, and noticing one of them on a Cucumber frame, I took a leaf with some aphides on it, placed the lady-bird in the midst of them, and watched the result. No sooner had the little creature recovered its equilibrium than it set to work and devoured the insects as fast as it could swallow them, and several not being within reach of its mouth, they were hooked towards it with its "fore paw," in the same manner that a cat will do with a mouse. "Here, then," said I, "is an end to all my troubles; no more trouble with tobacco now."

I instantly set to work, and with the assistance of one of my men in a very short time collected upwards of a hundred lady-birds; these were quickly transferred to a three-light Cucumber frame, and it was astonishing to see the rapidity with which they dispersed themselves among the leaves in search of their favourite food. In a few days not an aphis was to be seen, and when the frame was opened during the day, I found occasionally some of the lady-birds making their exit, no doubt to find a fresh field for operation. The plants soon recovered their health, and are now succeeding well. A few lady-birds still remain, and seem to be very happy in their new quarters.

I tried the same experiment in a small Cucumber house, but not exactly with the same results; the lady-birds disappeared as fast as I put them in, and I was not long in discovering that the depredator was a fine large toad I had kept there for another purpose. I need scarcely add that he was soon removed to another department, and, perhaps, at a future time I may call upon him.—G. S.

THE CHEROKEE ROSE.

The legend of the Cherokee Rose is as pretty as the flower itself. An Indian chief, of the Seminole tribe, taken prisoner of war by his enemies, the Cherokees, and doomed to torture, fell so seriously ill that it became necessary to wait for his restoration to health before committing him to the fire. And as he lay prostrated by disease in the cabin of the Cherokee warrior, the daughter of the latter, a young, dark-faced maid, was his nurse. She fell in love with the young chieftain, and, wishing to save his life, urged him to escape; but he would not do so unless she would flee with him. She consented. Yet before they had gone far, impelled by soft regret at leaving her home, she asked leave of her lover to return, for the purpose of bearing away some memento of it. So, retracing her footsteps, she broke a sprig of the white Rose which was climbing up the poles of her father's tent, and, preserving it during her flight through the wilderness, planted it by the door of her new home among the Seminoles. And from that day this beautiful flower has always been known, between the capes of Florida and throughout the Southern States, by the name of the Cherokee Rose.

It is of rapid growth, and soon forms a hedge as dense as it is beautiful. It runs along the roadsides likewise, converting roads and fences into thick banks of leaves and flowers. It climbs to the tops of high trees, hanging its festoons among the branches, or letting them droop gracefully to the ground. In fact, this showy wild flower, with its five white petals and centre of gold, imbedded as it is in so many brightly-shining leaves of green, gives almost a bridal aspect to the spring landscape, and well-nigh makes all the citizens' cottages look like homes of the poets.—(*American Horticulturist.*)

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Drosophyllum lusitanicum (Portuguese Yellow Sundew). *Nat. ord.*, Droseraceæ. *Linn.*, Octandria Pentagynia.—A native of Portugal, Spain, and Mauritania. Flowers yellow.—(*Bot. Mag.*, *t.* 5796.)

Mackaya bella (Natal Mackaya). *Nat. ord.*, Acanthaceæ. *Linn.*, Diandria Monogynia.—Native of the bed of the Tongat River, Natal. A beautiful shrub with delicate, pendant, white flowers veined with crimson.—(*Ibid.*, *t.* 5797.)

Aerides japonicum (Japanese Aërides). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Japan. Flowers white, blotched with purple.—(*Ibid.*, *t.* 5798.)

Nertera depressa (Depressed Nertera). *Nat. ord.*, Rubiaceæ. *Linn.*, Tetrandria Monogynia.—Dr. Hooker says—"Though when in flower one of the most insignificant of flowering plants, when covered with its translucent orange fruit, which it keeps for a long period, this is one of the most charming of rockwork plants. It is a native of the bleak cold Antarctic mountains throughout the southern hemisphere, where I have gathered it in Lord Auckland and Campbell Islands, the Falkland Islands, and Cape Horn; it also inhabits

Tristan d'Acunha, the mountains of New Zealand and Tasmania, and follows the Andes from Cape Horn to New Grenada.,—(*Ibid.*, *t.* 5799.)

Bignonia purpurea (Purple-flowered Bignonia). *Nat. ord.*, Bignoniaceæ. *Linn.*, Didynamia Angiospermia.—A magnificent stove climber, native of South America. Flowers lilac-striped with darker lilac.—(*Ibid.*, *t.* 5800.)

Cotyledon Salzmanni (Salzmann's Cotyledon). *Nat. ord.*, Crassulaceæ. *Linn.*, Decandria Pentagynia.—Native of Tangiers. A most beautiful rock plant. "A mass of brilliant golden blossoms relieved by red brown spots." Foliage brilliant green with crimson tips.—(*Ibid.*, *t.* 5801.)

Dianthus neglectus and Alpinus—"Dianthus neglectus is one of the loveliest of the Dianthus family. It combines the dwarf sturdy character and fine form of the handsome but rather fastidious Alpine Pink, with the vigorous constitution of the common or the Maiden Pink, and forms tufts which resemble short wiry grass. The leaves are slightly glaucous, concave, pointed, and, except in vigorous specimens, from half an inch to an inch long, the lower ones on the stems being somewhat longer. The flower-stems rise from 1 to 4 inches high, according to the position and soil in which the plants are grown, are freely produced, and each bears a solitary flower, or rarely two, about an inch, or, in vigorous specimens, 1¼ inch across, and of the purest, deepest, and most brilliant rose, the petals being quite level and firm-looking, with the outer margins slightly notched. In a wild state, and in poor sandy earth on well exposed rockwork, specimens may be seen in perfect bloom and robust health at 1½ inch high, and even less; but at lower altitudes and in a deeper soil, it is sometimes to be found 3, 4, or 5 inches high. In rich deep sandy soil in gardens it will also attain this height, or a little more, perhaps at some slight loss of neatness and compactness. It is surpassed by no Alpine plant in vividness and purity of colour. It is so dwarf in habit, and has flowers so large, that tufts of it might at first sight be taken for the Alpine Pink, Dianthus alpinus, but its narrow and sharply-pointed grass-like leaves immediately distinguish it from that species. The colour is also more vivid than in D. alpinus. It is happily very easily grown, unlike some of the other Alpine Dianthuses, flourishing freely in very sandy loam, either in pots or on rockwork. It roots through the bottoms of the pots as freely as any weed, is perfectly hardy, and a very gem either for chinks or level spots on rockwork, in all parts of these islands. The fact that it is so very free renders it useful for the front margins of mixed borders in fine sandy soil, but when planted thus, it should be surrounded by a few stones half plunged in the ground, to prevent evaporation and guard it from injury. It is a native of the highest Alps of Dauphiny and the Pyrenees, Switzerland, and Italy, and is easily increased by division, and by seed. It was introduced to cultivation by Messrs. Backhouse, of York."—(*Florist and Pomologist*, 3 s. ii. 217.)

NOTES ON PRIMULAS.

Primula.—This is a very beautiful and interesting group of hardy border and rock plants, which in bygone years was much admired and extensively cultivated in this country, but latterly it has been entirely neglected, at least in the gardens of the rich. It is rather astonishing that it should be so; Primulas are so fragrant, so beautiful in colouring, and so neat in habit; and the majority of the species, flowering as they do in spring and early summer, present a character so desirable, that one would think lovers of flowers, whether professional or amateur, could not easily forget or forego it. There are signs, however, of the old love being taken up again. Some beautiful varieties of the Cowslip and Primrose are found very useful in the spring flower garden, for which they are very fit; and the catalogues of florists and seedsmen are swelling with new species and varieties, in addition to many old and well-known sorts.

The majority of Primulas are very accommodating in cultivation, adapting themselves to many kinds of soils and situations, but are most at home in sandy loams, deep and moist, but well drained, and in moderately shady positions. They are easily propagated by seeds, cuttings, and division, the last being the simplest and easiest process where large increase is not an object. In laying in first stock, seed is the best and cheapest way in the case of the varieties of P. Auricula, Primrose, and Polyanthus, unless fine named sorts are wanted, when they must, of course, be purchased in plants, and by name, the same as with other florists' flowers; and the finer and more rare species must be got in the same way, because seeds of these are not always procurable true in this country. For a couple of months or more after sowing, the plants do not require much room, and are liable to be destroyed by slugs and other pests, whilst in the tender seedling state. A cold frame, hand-lights, or glasses, should therefore, if possible, be devoted to them, in which they will be more easily guarded against all enemies than if they were in the open ground. If many sorts are to be sown, small pots should be used to sow in, and they should be plunged in sand or coal ashes. The soil should be sandy loam, peat, and well-decayed leaf mould, in equal proportions, with plenty of sharp sand to keep the whole sweet and open. Sow thinly, and keep the soil regularly moist till the plants appear, when caution in watering will require to be exercised to prevent damping, to which Primulas are all rather liable in their first stages from seed. As soon as the plants are big enough to handle, they must be pricked-out thinly in pans, pots, or boxes, and returned to the frame, or set in a shady, warm, sheltered place, and well attended to with water, taking care, however, not to allow the soil to become stagnant with too frequent waterings, which would very soon be followed by sickness and death to the plants.

Primulas delight in moisture in the growing season; but a good sound watering at intervals, not daily dribblets or sprinklings, is what they want. When the plants have made sufficient roots and bulk of leaves they may be transferred to their permanent quarters, and well watered after planting, when they will need little more attention for the season beyond keeping them clean. If the seeds are sown in the end of March, the plants, treated as above directed, will bloom the following spring. In the case of getting up large quantities of Primroses and Polyanthuses, for the purpose of planting out in woods and such-like places, the foregoing directions would be troublesome and expensive, as these are only meant for the more valuable and rare species and varieties. The common varieties are best sown on a warm border in the beginning of April, in beds, broadcast or in drills, and, when fit to handle, planted-out in nursing lines in rich soil well manured with old hotbed dung. Cuttings are best put in in spring, when growth has fairly begun; the same soil as recommended for seeds is suitable for cuttings. Division should be done first after flowering is over, unless large increase of particular sorts should be desired, or when the plant is very weak, and would obviously be invigorated by being divided immediately before flowering commences; in such cases everything should be done to prolong the growing period, and all flowers removed as soon as they can be got hold of.

Under the name P. veris, Linnæus included the three forms of Primula most common in this country—the Primrose, P. vulgaris; the Oxlip, P. elatior; and the Cowslip, P. veris of modern botanists, being considered by him essentially the same for the purposes of science. But to gardeners and florists it is convenient to distinguish between the three forms, which are well marked and pretty constant in cultivation, at least, P. veris, the Cowslip. The common flowerstalk in this form rises considerably above the leaves, supporting an umbel of flowers; and in the single varieties, the corolla is small and cup-shaped, features that are lost sight of in the double varieties, or florists' Polyanthuses. From this form there are many varieties, some of which are most beautiful in their season, and worthy a place among choice plants. The commoner single sorts are suitable for planting in woods, and on banks, and about the edges of masses of shrubs.

P. vulgaris.—The Primrose is distinguished from the Cowslip by the flowerstalks having the appearance of springing directly from the root, and bearing each only one flower; there is, however, a common footstalk so short as to be concealed by the leaves. The corolla in the Primrose is larger than that of the Cowslip, and flat. There are many very interesting and beautiful varieties of Primrose, both single and double; the single varieties need not be enumerated, but are very useful for planting out in clumps or patches, as recommended for the commoner forms of Cowslip. The best of the double varieties are the flesh-coloured, the white, the sulphur, the lilac, the red, the coppery, and the dark purple; the last three are rare, and difficult to procure. All are invaluable for the spring flower garden, for rockwork, and for many other purposes in the kitchen and fruit gardens.

In *P. elatior*, the Oxlip, the common flowerstalk is generally shorter and stouter than that of the Cowslip, but is variable in length and strength; always, however, showing the umbel above the foliage, and the corolla is broader and flatter than that of the Cowslip. This is the least constant form of the three, and

its varieties are less numerous and interesting than those of the other two; they are mainly useful for planting along with the commoner sorts of Cowslip and Primrose in woods and such-like places.

P. Auricula is the parent of the well-known varieties of stage and border Auriculas. In its native habitats on the German, Swiss, and Italian Alps, it is rather a variable plant, but not to such an extent as to shadow forth, even remotely, the endless and beautiful combinations that have sprung from it in the florist's hands. Yellow and red are the most common colours in nature, with purple occasionally, and selfs are more common than variegated varieties, which is also true of the majority of florists' varieties raised, only the variegated forms are the most favoured. It would take more space than can be allowed here, to notice in detail the method of cultivating and raising the finer varieties, which have been most favoured by florists; and it is the less necessary to do so, because treatises on the subject have been long in existence, and give details ample and curious enough to satisfy the most particular inquirer. Almost any of the varieties are worthy of cultivation, were it for no other purpose than that of yielding early crops of cut flowers out of doors. Where these are wanted in quantity, the fragrance and pretty colours of the Auricula render them very desirable. All that are suitable for this purpose may be grown in the borders of the kitchen garden, about the margin of shrubberies, &c.; and they will succeed in any common garden soil, if not too heavy and wet.—W. S. (*The Gardener.*)

PLANTS FLOWERING IN SEPTEMBER.

Sept. 2. Tritoma Uvaria grandiflora
Delphinium formosum
Aconitum autumnale
Napellus versicolor
Ajuga genevensis
reptans
Zinnia elegans
Artemisia maritima
vulgaris
Aubrietia purpurea
Helianthus annuus
Bupthalmum salicifolium
Escallonia rubra
Fuchsia globosa
Campanula muralis
Hostii
Chrysocoma Lynosyris
Clematis cærulea
tubulosa
Cramhe maritima
Dactylis glomerata variegata
Crucianella stylosa
Dracocephalum canariense
Erythræa Centaurium
Eupatorium cannabinum
purpureum

NEW BOOK.

A Book about Roses: how to Grow and Show Them. By S. Reynolds Hole. W. Blackwood & Sons.

A very captivating book, containing a great deal of valuable information about the Rose and its culture, given in a style which cannot fail to please. The following is an extract relative to the Maréchal Niel Rose:—

"There seemed to be at first some hesitation among our Rose-merchants as to the propriety of a union between this delicate beauty and that rough, wild vagabond, the Jolly-Dog Rose; and it was 'sent out' generally budded or grafted upon the Manetti, or recently struck on its own roots, about the size of a toothpick. We have since discovered that, as fair damsels love stalwart knights, this Rose grows and blooms most vigorously when budded upon the Briar. This is the best stock for it, so far as my experience goes; but there is another with which it mates most happily, and of this I had last season a somewhat curious proof. Be it known, then, and *apropos* of mates, that the lady whom, on an interesting occasion, I endowed with all my worldly goods, does not avail herself of my matrimonial munificence with regard to my show Roses, but contents herself during the exhibition season with the produce of certain trees exclusively appropriated to her. One morning, towards the end of May, I listened with amused incredulity to her announcement, that she 'had just cut a beautiful bloom of the Maréchal;' and being perfectly sure that there was no tree of that variety in her collection, and no expanded flower on my own, I ventured to ask, with affectionate sarcasm, which of her plants had distinguished itself for life by this grand supernatural victory? The prompt answer was—'Gloire de Dijon: go to my room and look!' I went, expecting to see some abnormal specimen of the flower, and I found in all its loveliness, Maréchal Niel! Thence to the branch from which it came, and then the mystery was explained. I had mentioned to my gardener, in the preceding summer, some remarks which I had read from Mr. Rivers the younger, recommending the Gloire as a stock for the Maréchal. He had tried the recipe, as I now advise my readers to try it, and had first perplexed and then pleased me with the prompt success of his enterprise."

NUNEHAM PARK ONION.

In the "Report on Onions," in The Journal of Horticulture, page 286, the writer says that "the Nuneham Park is a thick-necked variety of White Spanish." Now, if the specimens exhibited at the Royal Horticultural Society, both by Messrs. Barr & Sugden and myself, had been examined, it would have been seen that they were of the flattest and most even shape, without the slightest approach to a "neck," of the whole collection on the stages.

Now for my own opinion on the merits of the Onion which I have studiously avoided pushing forward in any journal hitherto; but as I am backed up by scores of gardeners all over the country, I will maintain that what I said at first is perfectly correct—that it grows to the largest size and produces the

heaviest crop of all Onions, and this has been tested over and over again with most of the known varieties, by being sown side by side and under the same treatment throughout the season. In fact, so distinct even in its earliest stages is the growth, that no difficulty exists in plainly discerning its robust constitution. Another grand feature is, that of all Onions it is the most mild-flavoured, and many who cannot touch an ordinary Onion will eat this and enjoy it. I am amongst that number, and frequently have one roasted in its jacket for supper. And yet again another important feature; it is pale-skinned, white-fleshed, and keeps longer than any other Onion, not excepting James's Long-keeping.

I hope some of your readers will report through your pages the sorts they have grown this year, giving the size of the plot of ground and weight of the crop harvested.—James Cutbush, *Highgate*.

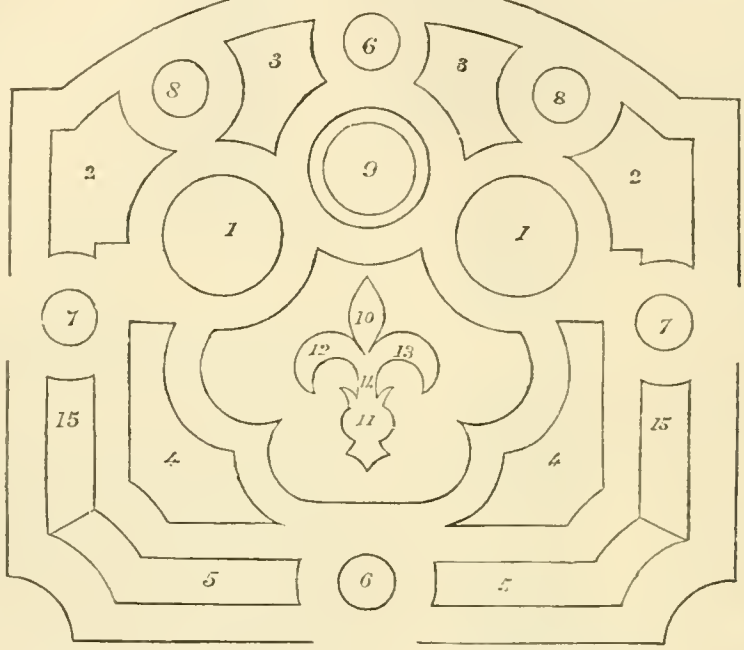
FLIXTON HALL, SUFFOLK.

Having just had the pleasure of spending three or four hours at the above-named place, a few notes may be interesting to some of your readers.

Flixton Hall is the residence of Sir A. Shafto Adair, Bart., and is a mile and a half from the Homersfield station on the Waveney Valley branch of the Great Eastern Railway. It is five miles from Bungay, and twelve from Beccles. On arriving at the Homersfield station I could see that some great mansion was not far distant, as the platform and windows were in a blaze with flowers and other garden ornaments. The road from the station to Flixton leads through a beautiful park 500 acres in extent, nicely undulated, and well stocked with fine Oak, Scotch Fir, Beech, and other forest trees, and upwards of five hundred head of deer.

Flixton Hall was burnt down in 1846, and rebuilt by A. Salvin, Esq., architect. It is a noble pile of red brick building, in the Elizabethan style of architecture. The carriage front is on the north side of the Hall, and is partly surrounded by a very beautiful and massive parapet of Portland stone, ornamented with coloured stone, under the direction of G. G. Scott, Esq. The enclosure is gravel, 240 by 100 feet. Three very handsome wrought-iron double gates lead to this front. These gates were made by Mr. Skidmore, of Coventry, and are much admired for their superior workmanship and ornamental character. An avenue 220 feet wide planted with Plane trees leads straight from the centre gates across the park, and has a very imposing effect. About 70 yards from the centre gates on the left-hand side is a fine old Oak, which appears to have been much shattered at some time. On making inquiry I was informed that about sixty years ago the yeomanry cavalry, one hundred strong, chiefly tenants on the estate, used to meet in this park several times in the year, and when the day's exercise was over they returned to the Hall by this tree, at which they discharged their guns. Nearly all the top branches were shot off, but the tree has somewhat recovered since that time.

At the south front and adjoining the Hall is a building 90 feet by 15, filled with a large number of ornamental vases of various sizes, for flowering and ornamental-foliaged plants during the autumn, winter, and spring months; also ornamental vases, which are filled with flowers and suspended from the roof. A very pretty flower garden on grass is on this front, the beds being all edged with stone; they are well filled, partly on the massing and partly on the mixed system. The good old Verbena Purple King has a leading part in the arrangement. The following rough sketch will show how this garden, measuring 170 feet by 150 feet, was planted this year.



1. Centre, Colaus Verschaffelti; Calceolaria Aurea floribunda, Pelargonium Flower of the Day. Border, Verbena Purple King mixed with Grania elegans.
2. Pelargonium Tom Thumb. Border, Verbena Purple King.
3. Pelargonium Stella. Border, Pelargonium Golden Chain.
4. Pelargoniums scarlet, white, and pink, mixed with Ageratum.
5. Calceolaria Kentish Hero.
15. Pelargonium Brilliant.
6. Pelargonium Flower of the Day.
7, 8. Calceolaria Aurantia.
9. Vase of mixed flowers.
10, 11. Verbena Purple King.
12, 13. Verbena Defiance.
14. Centre, Verbena Snowflake. Nos. 10 to 14 are surrounded by grass, the rest by gravel.

When seen from the upper windows this garden must have a very beautiful appearance.

On the left hand, leading from the Hall, and a few yards from it, is the conservatory, 100 by 21 feet, well filled with Oranges, Shaddocks, specimen Ferns, and other conservatory plants, including climbers, and two splendid plants of the Brugmansia alba covered with their large blooms, looking something like two mountains of snow, so thickly set were the blossoms. In the centre of the conservatory is a neat fountain with gold and silver fish, various Ferns being planted out all round, and from the frequent playing of the fountain they seemed to be quite at home. One end of this house is fitted up as an aviary, and is well stocked with choice birds.

On quitting the conservatory, just beyond the flower garden we find a sunk croquet ground 170 ft. square, which is reached by three flights of stone steps. On the ground level, and partly encircling the croquet ground, is a large collection of Aloes of great size and beauty. Beyond this the ground is in course of alteration, a great mass of earth having been removed so as to obtain a gentle slope to the park, and other improvements are being made.

On the western side of the mansion is a broad, sunk gravel walk, 130 yards long, which leads to an ornamental piece of water. About 5 feet above each side of the walk there is a series of beds, eighty in number, well filled with choice plants; Ricinus, Gladiolus, and other tall plants being placed in the centre. Beyond the beds, on the left-hand side of the walk, is a wall 10 feet high covered with Ivy, and a ribbon border, 330 feet long and 6 feet broad, at the foot, which is planted thus—First row, Cerastium tomentosum; second, Campanula (blue); third, yellow Calceolaria; and fourth, scarlet Pelargonium. The mass of green Ivy foliage is a fine setting-off to the plants beneath it. In the ornamental piece of water above-mentioned are two islands, with a fine specimen Oak on each, and to look at those Oaks one would think they had been planted for years. A large tea-party was given in

this pond last year—I do not say in the water, for I believe the pond was dry, like most others, at that time.

Retracing my steps a short distance, I entered the kitchen garden, which is well cropped with the best of vegetables. A large piece of Henderson's Short-top Beet was a beautiful sight, level as a die, all the leaves from 3 to 4 inches high, and not "a rogue" amongst them. The roots were of uniform size, 4 inches in circumference, and of a fine dark colour. This is just the sort for a nobleman's table. Onions were remarkably good, larger than the general run this year.

Fruit of all kinds has been very plentiful, with the exception of Peaches, Nectarines, and Apricots, which have not been a good crop anywhere.

I next entered a span-roofed stove, 50 feet by 12, in which there was a collection of plants, including Orchids, Ferns, and other choice plants in a thrifty condition. Blooming and hanging in graceful profusion from the roof were Cissus, Allamandas, and Passiflora princeps, affording a delightful shade to the plants beneath them. The stove is heated by hot-water gutters, which create a humid atmosphere in which almost all stove plants luxuriate, and on one of these gutters Mr. Short has contrived a lot of boxes, 9 inches wide and 6 inches deep, half filled with sand, with moveable squares of glass to fit at the top, and which work in a grove for the purpose of giving air, &c. As Mr. Short said, "These boxes are just the things for striking anything and everything requiring heat."

I then entered an orchard house 70 feet by 6 feet, well filled with Peaches, Nectarines, Apricots, Plums, Figs, &c., all planted out and in good health. Unfortunately, this house is not heated, and as with almost all other orchard houses without heat in the blooming season, the crop has been almost a failure. Mr. Short proposes having a flow and return pipe before another season, and everyone else having such a structure without the means of applying heat when the trees are in bloom, should adopt the same precaution.

The next house is a span-roofed greenhouse 50 feet by 14, ready to receive a collection of Azaleas and other hardwooded plants. Another structure 25 feet long by 15 feet wide, contains a large stock of bedding plants coming on for next season, all in excellent condition. In a vinery 50 feet long by 13 feet wide, there was a good crop of fruit, chiefly West's St. Peter's and some other old sorts. I believe Mr. Short intends planting some newer varieties ere long. The next structure was a Peach house 50 feet by 13 feet, from which a good crop had been gathered in June. Then there were a vinery 30 feet by 12 feet, of which the produce was just finished, and an early vinery 30 feet by 12 feet, which came in in May, the Vines being pruned, and at rest.

There are several ranges of pits heated by hot water, containing some good Pines, Melons, Cucumbers, Capsicums, &c., and several hundred pots of Roses, Mignonette, &c., in good condition for early forcing. A large batch of Strawberries in pots, showed that they had been potted early and well taken care of.

Several fine rows of Sweet Peas divide some of the kitchen-garden crops from the main walks, leaving a margin between the Peas and Box edging for sweet-scented flowering plants, such as Mignonette and Stocks. Mr. Short has a Gooseberry —a seedling, I believe— with the fruit striped green and red. I also noticed a row of Skimmia japonica well fruited. This, I believe, is to be taken up for table decoration.

I next entered Mr. Short's cottage, which is a square, substantial building, facing the park, but just inside the garden, with a flower garden in front taken out of the park. It is a real gardener's cottage, being covered with Roses from top to bottom. I noticed inside the dwelling that experiments were going on there as well as in the most important parts of the grounds. Mrs. Short has reared a very pretty seedling Pelargonium, and has a young Oak tree growing in a vase of water, the foliage and roots appearing quite healthy. Fancy the Oak being made an aquatic.

Various improvements are projected. A new kitchen garden is about to be made, and the old one is to be cleared and planted with choice shrubs. New carriage drives are marked out, and there is a gasometer nearly finished, which is to contain gas for five hundred jets already fixed, and which will light the three carriage entrances, the hall, the gardener's cottage, the farm, stables, &c. This will be a great boon to all concerned, and a great saving of property in the end. When all the alterations which are in progress, and those which are contemplated, are finished, Flixton will boast of having one of the finest gardens in the eastern counties, and great credit is due to Mr. Short, the head gardener, to whom the care and arrangement of the gardens are entrusted.—J. Perkins.

P.S.—I forgot to mention that in the orchard is a large Oak tree, the branches of which spread into three different parishes —viz., Homersfield, Flixton, and St. Cross. The age of this tree is not known, but its branches cover a circumference of 297 feet.—J. P.

GRUBS.

In "Doings of the Last Week," by "R. F.," there are some remarks on these annoyances, and I hope he will pardon me if I venture to say that in those remarks there are some errors. Firstly, "R. F." says that "the worst form of Cabbage grub is the larva of the cockchafer." Here, I think, he is quite mistaken; the larva of the cockchafer is a feeder chiefly on the roots of the grass tribe. I have never found it in the garden soil, unless on an old burnt weed heap, where grasses are growing. It is, I believe, a disputed point whether these and the larva of the crane fly or daddy-longlegs, also a grass-feeder, feed on the roots of the grass tribe or on the soil in which the Wheat or other grass may be growing; the result is equally the same—the death of the herbage. To this point I will return presently.

The eggs of the cockchafer are yellowish in colour. The full-grown larva, over 2 inches in length, is really a disgusting object, having a large yellowish-brown head, armed with very formidable mandibles; its six legs are very strong, placed near the head, and are of the same colour as the head; the rest of the body is whitish yellow, except that towards the tail there is generally a large portion, say a third, of the whole insect that is brownish blue or blue in colour. It is invariably doubled up on itself, so that the tail is, as it were, clasped by the legs. There is no resemblance whatever between the larva of the cockchafer and that of the crane fly; the latter is of a uniform brown colour, about 1½ or 2 inches long, and about one-quarter the diameter of that of the cockchafer, which is half an inch in diameter. "R. F." is right in stating that the crane fly larvæ have no feet, but I think they have a few prominences at the head and tail which do duty for the same.

Rooks greedily devour the larvæ of the cockchafers, and so, I suspect, do starlings, probably also blackbirds and thrushes; but our beautiful songster, the lark, is a grand enemy to the crane fly larvæ when it has young, and I have seen its nest with dozens of dead larvæ strewed around. The cockchafer, the perfect insect, I mean, feeds very constantly in the daytime, preferring the Oak and Maple; the former is often stripped by it. Here let me be just; the sparrow is no favourite with me, the idle vagabond prefers hopping to our fowl-yards for food to searching for his daily bread, but during the cockchafer-time he devours not a few, searching for them under the leaves of the Oak, stripping off their wing-cases, and feasting on the dainty morsel, and I have often seen the ground under Oak trees strewn with the wing-cases, and watched master cock sparrow at work. The cockchafer remains three years in the larva state.

I have said it is a disputed point whether they feed on the roots of the grass tribe or on the black earth in which the grasses grow. I think the great number of larvæ are in some degree coloured by their food; for instance, I have removed green larvæ of the Syrphus, one of the fly tribe, from Currant trees, where they were feeding on the green aphis, to a Morello Cherry, and in a day or two the black aphis food has perceptibly altered the colour of the larvæ. The fact that, if you crush the crane-fly larvæ, the contents are black and earthy-looking, also favours the idea that the earth may be its food, but with underground livers it is difficult to decide.

Supposing, however, that I am right in saying that the cockchafer larvæ turn up their noses, if they have any, at Cabbages, who are the wrong-doers? One larva that acts in this way at the present time of year is that of the various tribe of dart moths. I hear the larvæ of these moths are known among gardeners by the name of "leather-jackets." Are these the culprits? A very clever gardening friend of mine says that they are only to be got rid of by search and hand-picking.

Of course, with many of our pests the surest method of lessening them in the larva state, when they are usually most destructive, is to destroy the perfect insect. Cockchafers are so easily collected by children in the daytime, and to those who keep our feathered friends—poultry, are so useful as insect food for them, that it pays to employ some children for the purpose. The first throwing-down of a cockchafer amongst a group of chickens is ludicrous enough. First, the horror and

amazement as they eye the monster, evidently doubting whether the ultimate verdict will be reversed, and the beetle swallow the chick; at last one more venturesome gives a peck, and by degrees summons up sufficient courage to run off with it, followed by the rest, each in turn possibly undertaking the carrying business; then one bolts the dainty tit-bit. Henceforth the mystery is solved, reminding us of Charles Lamb's history of roast pig; for as the pigstyes were continually being burnt after the discovery of the luxury of roast pork, especially "crackling," so with the chicken, the second cockchafer is most unceremoniously seized and devoured. I do not doubt that chickens would pay the same attention to the crane fly, only that the latter, if not disabled, would probably not sham death, as does the cockchafer, but speedily fly away. When, however, they occur so thickly as they appear to have done latterly in some parts of the country, that they might be "swept up," as "R. F." says, then probably they would be so injured as to prevent flight. A little boiling water would make death certain, and I fancy chickens would eat them then; if not, they might still be useful as manure.—Y. B. A. Z.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Now is a good time to thoroughly drain any part of the garden requiring drainage, to replant the Box and other edgings, to mend the grass in these where it is not necessary to relay the whole, to prepare gravel, &c., for new walks, or for repairing the old ones, and to make any necessary alterations. Thoroughly trench and drain ground newly taken in, and every spare piece in the garden, choosing suitable weather. Care should always be taken not to operate on close, retentive, badly-drained soils when full of water, which they will continue to be if heavy rains prevail. *Broccoli* now becoming too luxuriant may be checked by laying it down. Some of the *Cauliflower* plants of suitable size and age should be potted and placed in Melon pits and frames, turf pits, or temporary pits made with a few stakes, and interwoven with evergreen boughs, furze, heath, fern, or straw. They may then be covered, when frost is likely to occur, with Pea haulm, evergreen boughs, mats, or anything that is convenient, laid on cross poles or sticks. A quantity may also be placed in warm, sheltered borders, or corners, and if taken up with balls of earth and sheltered temporarily, as above recommended, both Cauliflowers and Cape Broccoli can be secured in succession throughout the winter, until the early varieties of Broccoli come in naturally, thus securing a regular supply the whole of the year. Warm, dry borders and banks should be prepared for early Peas and Beans, so that time may be allowed for exposing the soil to the influence of the atmosphere. Secure the supply of the best *Red Cabbages* for pickling while they are sound and good, after they have had sufficient frost to stay their natural colour. Strong plants of *Lettuce* of the hardy kinds should now be planted in well-prepared, dry, warm situations to stand the winter. Small *Onions*, too, should be thought of while they are good, for the same purpose as the Red Cabbage. See that the Pea and Scarlet Runner stakes are snugly tied in bundles, stacked away neatly, and thatched with reed, straw, or evergreen faggots. Prepare in wet weather straw mats, thatched hurdles, &c., and tie Russian mats in readiness for use. Hoe and stir amongst all growing crops in suitable weather, and collect all dead and decaying leaves. Those who have spare ground should still continue to put out Coleworts and Cabbage plants, or if any strong plants of *Savoys*, or the varieties of *Kale*, should be left in the seed beds, by all means plant them out thickly—say at the same distance as for Coleworts. Those who are fond of *Turnip Greens* at an early season, if they have any overgrown bulbs left in the beds, should at once collect them, and plant them 1 foot apart on warm spots, or on sloping banks.

FRUIT GARDEN.

Remember in collecting the late varieties of Pears, that they do not generally come evenly to the proper condition to gather, but ripen in small patches, while others on adjoining branches cling firmly, and in some cases do not arrive at a fit condition to gather for several days. The storing of fruits, as well as the after-management, must this season be accomplished with particular attention. The Apples and Pears should be carefully wiped and regulated after sweating. The Medlars and Quinces should be collected in good condition. To select perfect Walnuts for storing, the best plan is to immerse them in water after the husks are taken off, and all that are quite perfect at once sink to the bottom, while the imperfect ones float on the top; even those which have the least possible deficiency in the kernel will float. Those which have sweated should be well cleansed, by being placed in a dry sack, and shaken by two persons from end to end; the friction will clean them perfectly, and then they may be stored.

FLOWER GARDEN.

In some localities the cold nights we have lately experienced must have greatly damaged the appearance of the more tender kinds of plants, and those which are to be saved should be removed at once. Proceed, therefore, with potting such plants with as much dispatch as possible, and if practicable a little artificial heat should be applied to help them to root before winter. In general, a show of spring-flowering plants is quite as acceptable as the more gaudy occupants of the parterre in summer, and steps should be taken to fill up the beds as they are cleared, for the purpose of contributing to the enjoyment of spring. A miscellaneous mixture of dwarf early-blooming shrubs, perennial plants, and bulbs, are most commonly planted; but in regularly laid-out beds, as in geometrical flower gardens, the disposition of colour should be carefully considered, as there is an abundance of spring-flowering plants and bulbs to form a rich and varied display, if properly arranged and carried out. Lawns will now require daily sweeping to keep them neat; roll constantly wherever the turf is hollow, to keep a firm sward. Clean gravel walks for the winter, and afterwards let them be well rolled, in order that the water may pass freely off the surface. All operations of planting, relaying turf, and border-making, should be actively proceeded with.

GREENHOUSE AND CONSERVATORY.

It not unfrequently happens in otherwise well-regulated establishments, that the conservatory is during the winter months crammed, without regard to order and neatness, with a miscellaneous assemblage of old family favourites, in the shape of large Myrtles, American Aloes, Orange trees, &c., all, perhaps, very useful in decorating certain and suitable situations in the open air during the summer months, but by no means proper objects in a modern conservatory, more particularly if it form part of the family residence, with which all good conservatories ought to be connected, and where, consequently, the greatest order and neatness are absolutely necessary. Those who are anxious to preserve this ornamental appendage to a mansion in all the beauty and order which is possible, will devise a variety of means for the preservation of plants during the winter months, provided room cannot be found for them in the other horticultural structures of the establishment, and as such plants will endure much hardship without injury, there will be no great difficulty in preserving them throughout an ordinary winter in temporary structures erected of any dry material, such as fern, heath, or furze, which can be conveniently obtained, taking care to provide the means of giving a portion of light and air on all favourable occasions. Air should be freely admitted to the conservatory whenever the weather is favourable, but it should be regulated so as to avoid draughts, which under any circumstances are injurious. Dry weather should likewise be taken advantage of to clean the surface soil of pot plants, and to wash the outsides of the pots to promote free evaporation from the soil during damp weather. Great attention should likewise be bestowed in keeping the shelves, stages, and paths free from dirt, decayed leaves, &c. These little attentions give houses an agreeable look at a season when flowering plants are becoming scarce. Conservatory and stove climbers trained under the roof will require an additional cutting-in to allow more light to pass to the plants underneath. Such as have done blooming may be well thinned out at once, and the remaining shoots tied somewhat more closely together. Hardenbergias, Kennedyas, and other early spring-flowering climbers should, however, not be disturbed at this season. Before placing Gloxinias, Achimenes, and similar plants to rest, let each be labelled, in order that no confusion may arise when they are wanted in spring. All the above keep much better in the pots in which they grow than anywhere else, and should be wintered in a room or shed where there is no danger to be apprehended from frost.—W. Keane.

DOINGS OF THE LAST WEEK.

Rubbish Heaps.—As a continuation of what was referred to last week, we may state that in places of considerable size, it is advisable to have two or three rubbish heaps in the course of the

twelvemonth, the oldest to be used first when all the bulky material is sufficiently decomposed. To give efficacy to such heaps of refuse, nothing is better than short grass, as its heating sets the whole mass fermenting, and the largest Cabbage stumps, Hollyhock stems, &c., thus soon become decomposed. The grass acts best when mixed with Cabbage stems, small prunings and clippings, &c., and when kept pretty well down, so that the heat from it will rise; and the surface should be covered with refuse soil, so as to prevent the fertilising gases from escaping, the strongest and most unpleasant to the sense of smell being most valuable when diffused and fixed in the mass. We have known such accumulations of short grass, left to themselves, become a perfect nuisance—nay, dangerous to the health of the workmen near them, whilst more spread-out and covered, they became valuable, and caused little or no offence to the passers-by. Even in a small garden, and especially where there is a lawn, and sides of walks to clip and clean, the quantity of rich excellent material that may thus be collected in a year is very great.

One great advantage of the short grass, and even a little stable manure, forming part of the rubbish heap, is that the heat not only decomposes what has rather too much woody fibre, as huge Broccoli stumps, but it also destroys many seeds, and drives away many insect enemies that otherwise would find a congenial home. We know in many cases it would save time to trench down vegetable refuse at once, and let it decompose slowly in the soil, and thus we have done with exhausted quarters of Broccoli, Borecole, and Cabbage; but such digging down did not improve the succeeding crop like a dressing from the rubbish heap, dug down or incorporated with the soil in the usual way. Besides, we have reason to believe that insect depredators often insert their eggs in the stems of vegetables, and if these are not well buried, the young larvæ could scarcely at first have better feeding ground; but when these are well sunk and well heated in a rubbish heap, there is more likelihood that eggs and larvæ will be destroyed.

A little salt or lime sprinkled on rubbish heaps will hasten the decomposition of organic matter, and make the heap more valuable; but much of the natural virtues of the heap will be retained by a surface-covering of soil, and a few barrowloads from the potting-bench, &c., may be left for the purpose, to be applied after depositing fresh vegetable matter. It is advisable, however, to have two or three heaps instead of one, and then they can be better attended to, and the one will succeed the other in fitness, to be applied as wanted. When woody refuse is charred, or strong weeds with some soil adhering to them, as couch and other grasses, are burned, the burnt earth, clay, &c., left, form one of the best materials for throwing over all rubbish heaps when in a state of fermentation.

We lately saw a very large oblong heap of the best dung decomposing just enough in a field, placed there to save carting a long distance when it was to be applied. This was turned over once or twice, and well mixed and heated; a good portion of its best properties would have escaped into the general atmosphere, but as a huge heap of twitch had been burned, the ashes and earth from it thrown over the heap and along its sides prevented the escape of the rich gases. All fermenting masses of dung will lose much of their nutritive properties unless some similar method be resorted to. But for living so much in the open air, many farmers would suffer in health from the huge masses of manure thrown up in their yards close to the dwelling house, and with nothing done to prevent the escape of some of the best properties of the manure. With the rains washing some of the best properties of the manure in open yards into the nearest ditches and rivulets, and the escape of the gases from heaps of such manure when thrown together, it is no wonder that artificial manures at a high price have to be added to make the old dung heap at all effective; these artificial manures, in many cases, doing little more than restoring what has been lost by our own carelessness.

Charring Woody Refuse.—We have such a quantity of woody rubbish, that we are anxious to char a lot of it, but cannot well begin in such fine, mild weather, as there is sure at first to be a great and disagreeable smoke from the loppings, prunings, &c. We say nothing now of charring large wood; that is done by having the fire well lighted and then excluding air, only admitting a little so as to secure slow combustion, but not so much as to allow the wood to flare, for then it would burn to ashes instead of merely being charred through. In general charring, the best covering is turf, and then earth over it. In charring a lot of small wood, prunings, branches, Hollyhock stems, &c., it would be too much trouble and expense to use turf for such a purpose, as a large heap soon becomes small when the fire has taken hold and the charring commences; and treat as you will, unless you faggot previously, which, again, is too much trouble for the result obtained, the heap will be apt to sink unequally, and thus air will find its way in and cause the heap to flare unless watched. For charring all such wood rubbish, nothing is better than a slight covering of mowings and sweepings of grass and tree leaves, with a little earth over them, until the heap subsides, after being well heated, when a little more earth may be added. The charring heap and the rubbish heap will thus mutually assist each other.

There is one more matter to be considered about the charring heap, and that is, before burning it up, or rather making it small by charring, wherever wood is scarce a lot of the best prunings should be made up into bundles for lighting the hothouse and other fires. A man with a bill and an elevated block will soon make up a number of these little bundles from prunings, and if the heap is near a shed the work may be done in a wet day. The little bundles may be from 12 to 15 inches long, and from 5 to 6 or more inches in diameter, have a small handful of straw in each, be tied with a small band of straw, and be piled in a shed; they will always be dry and easily kindled when wanted.

All these are operations that may receive attention now, when a little breathing time can often be had after the summer. We shall shortly mow a part of the pleasure grounds in which the grass is too long and rough for our machines, and we should like to make a base of the grass and some stable litter, turn over part of our more recent rubbish heap upon it, and place more grass in alternate layers. Such a heap, we know from experience, would turn out well after the New Year.

Since writing the above, a favourable change in the wind carrying the smoke from the direction in which it would have been unpleasant, we were tempted to try and lessen the bulk of a lot of spray wood, prunings, twigs, &c., and we managed to char a quantity. For all small twigs it does not answer to continue the charring process long; from twelve to eighteen hours, or even much less, are generally sufficient, because take what care you will, with such small brushwood to deal with, the air is apt to find its way in; and even bank up as you will, there is so little substance to fall back upon, that you are apt to obtain ashes instead of charred material. Of course, what we have is rather rough, and had to be watered as soon as taken out; but when cooled and passed through a fine sieve we obtained a large heap that will do for potting, pot-draining, &c., and another large heap of black dust, first-rate to serve for sprinkling and surfacing for cuttings, &c. What was left in our heaps we appropriated to burning up weeds, old soil, and stumps and stems that would have been of little use either in the charring heap or the rubbish heap.

Sawdust.—We have this pretty well charred, and therefore made useful, by mixing it sparingly with the brushwood charred; and though by leaving open conduits for drains for air we have sometimes been fortunate in charring it by itself in a heap, yet on the whole our success was very unsatisfactory, and the result hardly justified the labour and trouble involved. In many places sawdust, both hardwooded and softwooded, is often so abundant, that it is desirable to get rid of it, being of but little use so far as cultivation is concerned. If charred it would be invaluable as a surface-dressing, and as helping to keep enemies away. Anyone who can tell of a simple, easy, inexpensive process, by which the charring of sawdust can be accomplished without ovens, retorts, or anything of the kind, would be conferring a benefit upon many.

Perhaps the most useful purpose sawdust can be applied to in a garden is, when tolerably fresh and dry, using it for giving a mild bottom heat to plants plunged in it. Thus used it will retain its heat for a long time. The only drawbacks are, that if the bottom of the pot rests on the sawdust the hole in the pot will be so apt to be clogged as to prevent water passing off freely, however well the drainage has been attended to; again, fungi, &c., are so likely to appear, as to require watching and destroying by quicklime applications.

We have seen sawdust recommended for packing fruit, roots, and even banking-up Celery, but for none of these purposes should we like to use it, as it is likely to heat and always to give a disagreeable taint to whatever is edible that comes in contact with it. In plunging plants in it, it is easy to avoid choking by the battering-up of the drainage hole; but neglecting the precaution of looking after such matters has ruined many a plant. The more water was used the more would the

sawdust insinuate itself gradually into the hole, until it became as impassable to water as a cork. We have seen dry sawdust used with good effect when mixed with tan that was rather wet; but even then, though pleasant to work amongst, and moderating and continuing the necessary temperature, the presence of fungi, &c., was often troublesome, and they spread with great rapidity. Charring would be the means of making sawdust most useful.

KITCHEN GARDEN.

We have been more fortunate than our neighbours generally in escaping the ravages of *grubs* this season, though Lettuces and even Cabbages have been attacked in solitary cases. We attribute this escape to anything but peculiar treatment of our own, though a little extra care in looking after the grubs and making places uncomfortable to them may have had something to do with it. From most parts the accounts we receive would lead us to suppose that Cabbages and Cauliflowers just planted out suffered most. In our case we have suffered most as respects fresh-planted Lettuces. Of Cauliflower turned out in squares, to be covered ere long by hand-lights when they can be spared, none as yet has been touched. The ground was forked over several times previously, some hot ashes from one of the burning heaps, not much less hot and alkaline than lime, were forked-in, and when these had lost their heat the plants were dibbled in with a little rough sand on the surface, and then a little of the same warm ashes and burned earth from the heaps was laid at a little distance, as a cordon round them, along the ground. We can see in a dewy morning by the slime left that slugs had been attracted by the scent of the young Cauliflower plants, but had turned their heads a different way as soon as they came to the unpleasant barrier. It is just possible that our seed beds of Cabbages, Lettuces, Cauliflowers, &c., owed their freedom from the grubs to somewhat the same cause, though we fear that would be jumping too rapidly to conclusions.

We trusted lately that the grub might not care for seed-beds, as ours were untouched; but as if to dispel any such fond delusions, a market gardener who raises numbers of Cabbage plants not only for his own land, but to supply several market towns with plants, has been unable, after repeated sowings, to obtain plants this season, the grub clearing all before it almost as soon as the plants were above ground. As formerly stated, we used to suffer most just when the plant was in a languid state from transplanting. The market gardener alluded to has not had the chance to transplant. He also says, it is all nonsense about soapsuds, soot, and lime being of any use in driving grubs away, as they are quite comfortable in little heaps of soot. We can only express our regret at this being the case, but when we suffered, these means were so far effectual with us. We agree that no plan is so good as catching and killing them, but we have doubts of what he thinks is the next best plan—namely, trenching them down before planting. We should be afraid that those we turned down would soon find their way up again, whilst those which had gone down, thinking they had devoured enough, might, if brought up nearer the surface, be tempted to take a fresh lease of grub existence, and nibble a few more plants before they entered on their rest or chrysalis state. We should have more faith in surface-stirring, with a little application of those unpleasant surface dressings noticed above. We are, however, by no means satisfied with our knowledge on this subject, and shall be glad of all information the result of close observation and of practical utility.

It is seldom that we have to deplore any evil, but we can easily conceive there might have been a worse one. Here is a man fretting because the grubs threaten to monopolise his young Cabbage plants, and yet if he would only look at his Coleworts, Borecoles, Brussels Sprouts, and Broccolis, he would be forced to own that he never saw them look more healthy and beautiful. Often he has seen the foliage ragged and torn to strips by the ravages of caterpillars, now he may search his place through and not find one. There is rarely a cloud that is all black, if we would only look at the break that lets the bright light through.

Seeds.—The statements, as published, of seedsmen anxious to get rid entirely of a deceptive system is very interesting, but we fear that many will be inclined to think they have been cheated, when there was every desire on the part of the merchant to use his customer honestly. For ourselves we have less faith in any legal enactments than in dealing with respectable houses and paying fair remunerative prices. In such cases if there is a little doubt about the seeds it will be frankly stated, and the user will be told to sow a little more thickly. Never were there more complaints about seeds not coming up than this season in gardens. We believe that in general seeds were never better nor fresher. The season, as respects dryness, when we could not counteract it by modes that could be adopted on a small scale, and previously adverted to, did much to prevent the germination of the seed, or to shrivel it up before the seed leaves appeared. There are many causes of failure too often occurring that we are apt to lose sight of. For instance: in sowing Cabbages, Lettuces, &c., twice at the same time, and treating all as we thought nearly alike, there were three favourite kinds of Lettuce of which we did not raise a single plant from any of these sowings, whilst all the rest came up well enough and so thickly as to show that scarcely a seed had missed germinating. Now, we might have come to the conclusion that the seed of these three sorts must have been beyond question bad, and yet the examination of the seed did not lead us to believe so, and rightly as the result showed, for on sowing the same kinds from the same packets to stand the winter, the seedlings have come up only a great deal too thickly—in fact, must be thinned to give them a chance of standing. Now, we fear that many of the complaints of bad seeds are more owing to something else than the fault of the seed merchant. Very likely, but for a press of other matters to attend to, we should have found out the reasons why two sowings proved abortive. The result shows it was not owing to the seeds.

We stirred the ground amongst Spinach coming on well, and strewed burnt earth and ashes between the rows; we also tied Lettuces, blanched Endive, earthed-up Celery, especially one fine bed of Dwarf Incomparable, so as to be in fine condition in a month, and hoed among young Onions. We watered Cauliflowers coming into use, earthed one Mushroom bed and spawned another in the house, put a little more rough hay covering over the beds in the shed, and sprinkled the covering with manure water, so as to keep a close moist atmosphere near the bed, in imitation of the best Mushroom weather out of doors. Put some old lights over Dwarf Kidney Beans in a turf pit, where we generally have them late, and gave a little protection to Vegetable Marrows that we may have a good gathering before pulling the plants up, as we want the room.

FRUIT GARDEN.

The work has been much the same as already detailed; collecting fruit, giving more room and less water to Strawberry plants in pots, in order that the present glorious sun may act on the buds, and ripen them, which is of more importance than huge leaves and plants. Some of ours are quite large enough. All trees in orchard houses should now be allowed to become dryish, not dry, that the sun may have more power to mature the wood.

ORNAMENTAL DEPARTMENT.

This second summer is making the flower garden quite gay, and but for falling leaves we might consider ourselves in the beginning of August. The beds show little of the holes made by cutting-taking, which we could not help, though we would rather avoid. The late rains will produce fine Calceolaria cuttings when wanted. We shall be thinking about them at the end of the month. One great essential of success is having fresh soil to put them in. We do not see our old friend Mr. Robson's name so frequently as we used to do. Let us urge on all, and especially the holders of small gardens, their reading carefully the late article on raising some bedding plants from seeds. We would add that a small packet of Cineraria maritima seeds, say for 6*d.*, will yield a multitude of seedlings. Unlike the Centaures, however, the seedlings in the first year are rather green-leaved, but they come white in the second season. We also agree with him that the Verbena venosa is one of the best of the tribe for bedding, and it is easily obtained from seeds as he states. Sometimes the seed is long in germinating, and is often thrown out prematurely. When once raised, its creeping underground roots furnish plenty of plants.—R. F.

TRADE CATALOGUES RECEIVED.

William Paul, Waltham Cross, London, N.—*Rose Catalogue*, 1869-70.

T. S. Ware, Hale Farm Nurseries, Tottenham, N.E.—*Catalogue of Ornamental Trees, Shrubs, Climbing Plants, Fruits, Roses, &c.—Select List of Spring Flowers.*

J. Scott, Merriott, Somerset.—*Descriptive Catalogue of Nursery Stock.*

Thomas Rivers & Son, Sawbridgeworth, Herts.—*Descriptive Catalogue of Fruit Trees, by Thomas Rivers*, 1869.

Paul & Sons, The "Old" Nurseries, Cheshunt, Herts.—*Rose Catalogue*, 1869-70.

Jean Verschaffelt, Fanbourg de Bruxelles, Ghent, Belgium.—*Catalogue des Plantes—l'Automne*, 1869, *et Printemps etEté*, 1870.

COVENT GARDEN MARKET.—October 13.

Trade still remains dull. Hothouse fruit is more than equal to the demand. Wall fruits, such as Peaches and Plums, are almost over. Large quantities of Grapes continue to come in from Jersey, keeping prices of second-rate English Grapes down.

FRUIT.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

Books (*C. Lefebvre*).—Rivers's "Rose Amateur's Guide." (*Subscriber, Norwich*).—The "Fern Manual." You can have it from our office, post free, if you enclose sixty-four postage stamps with your address. (*M. E. H.*).—There is no edition of the "Hortus Britannicus" with plates of any kind, nor is there a work containing coloured plates of the groups you name. (*J. Matthews*).—"Wild Flowers of Great Britain," which you will see advertised this week.

Late Vines for a Vinery (*Rupert Gaulois*)—Your selection (four Lady Downe's, three Mrs. Pince, two Black Alicante, two Tottenham Park Muscat, one Muscat of Alexandria, one Bowood Muscat, one Muscat Hamburgh, one Gros Guillaume, one Trebbiano) is an admirable one; but you ought to have Madresfield Court. Suppose you have only three instead of four Lady Downe's, and substitute Madresfield Court for the fourth, you will not be disappointed. We wish we could recommend you a really good late white Grape instead of Trebbiano, but we cannot. We require a handsome late white Grape of superior quality. Let raisers of Grapes see to this.

Fruit-tree Stocks (*Nemo*).—You will be further forward two years hence by allowing your Paradise and Quince stocks one season's growth in the ground before grafting, than by planting in October and grafting the following spring.

Ribston Pippin Falling (*R. J. G. P.*).—You should have sent specimens to enable us to judge of the cause. It appears, however, to have been produced through a lack of support—a want of foliage on the spurs to draw to the fruit sustenance, which appears to have been all usurped by the strong shoot-development.

Colour of Grapes (*N. H. P.*).—The first sentence in our last answer fully replies to your query.

Pear (*J. S. A. G.*).—The Figue d'Hiver Pear is thus mentioned in "Hogg's Fruit Manual:"—"Fruit medium-sized, pyriform. Skin greenish-yellow, strewed with russety dots. Eye small, set in a shallow basin. Stalk half an inch long, thick and fleshy at the base, inserted obliquely, without depression. Flesh greenish, melting, juicy, sweet, and vinous. A second-rate Pear, ripe in November and December."

Verbenas (*M. E. E.*).—We cannot attempt to name the varieties of florists' flowers. They are in legions, and so often nearly alike that florists have a difficulty in distinguishing them when they have an entire plant before them. We think there are upwards of three hundred named varieties of Verbena.

Gardeners' Examinations (*C. F.*).—We cannot inform you which of the volumes of McIntosh's "Book of the Garden" is to be used as a text book for the examinations of the Society of Arts, but as no particular one is mentioned, we presume both are. We do not think it would be necessary for you to procure both of these and Thompsen's "Gardener's Assistant" as well; but we cannot say what the intention of the Society is; nor do we know if it is necessary to "have all the text books mentioned." You had better write to the Secretary, Society of Arts, Adelphi, London.

Messrs. Dickson & Sons (*James Hardie*).—Mr. Dickson died nearly two years ago.

Seedling Pelargonium (*T. E. B.*).—This seedling ("Geranium" you call it) had all its petals fallen. The truss is large, but of the colour there are many similar.

Roses under Glass (*O. E., Bristol*).—"A glass roof over a bed of Tea and Tea-scented Noisette Roses would be of great advantage, without protection at the sides of the same nature My opinion of Deveniensis, and, I may add, of Souvenir d'Elise Vardon is, that they have never been beaten. I have them now in profuse bloom on my south frontage. They have been in bloom all summer. When winter comes I put straw over their roots, and lean and tie a little Asparagus haulm against them, which is ample protection. I recommend Adrienne Christophle as distinct and very beautiful; and I hear well of Marie Sisley, and Madame Margottin is very good.—W. F. Radclyffe."

Wasps (*J. Prior*).—There are seven species of wasps in England. The specimens you have sent are of the large common wasp (Vespa germanica). Its nest, made in the ground, is shelly, and grey in colour. The small common wasp is Vespa vulgaris.

Specific Names of Plants (*Usil*).—The general rule is that when a plant is named after the discoverer or describer, the specific name is in the genitive singular, as Abies Douglasii, but in practice euphony is consulted. Two i's are employed when the Latin nominative ends in us or um, preceded by an i, as Douglasius, Douglasii; but only one i is used when the nominative is not so preceded, as Jackmannus, Jackmanni. In writing about many plants in a genus, some would say, for example, Gladioli, which is the Latin plural, but others would write Gladioluses, the English plural. It would seem pedantic to say Croci, Odontoglossa, Oncidia, Musæ, although these are the correct plurals of Crocus, Odontoglossum, Oncidium, and Musa. Custom is the only rule.

Planting Herbs (*S. J.*).—The best time to make new beds is at the end of March or beginning of April.

Hyacinth Compost (*Idem*).—Two parts turfy loam, one part old cow dung, and one-sixth sharp sand. Drain the pots well, and pot the bulbs at once. After potting plunge the pots out of doors in ashes, and cover with about an inch of ashes, and allow them to remain for six weeks, then remove them to a greenhouse or window, affording a position near the glass.

White and Blush Camellias (*Eve*).—*White:* Alba plena, Duchesse de Berri, Fimbriata, Mrs. Percival. *Blush:* Lady Hume's Blush, Triomphe de Leddi (striped rose), and Zoraide Vanzi. The Azalea bed should be planted now, or in mild weather until the plants commence to grow, but the earlier it is done the better.

Azalea not Flowering (*Pendragon*).—It is probably due to its growing too vigorously, and perhaps over-potting. Do you place it in heat to make the growths, and keep it cool, and well exposed to light and air?

Various (*Y. Z. N.*).—Charcoal used in plant culture is that from burned wood. Animal charcoal is not employed for such purposes. The special object of silver sand is to make the soil more open, and to keep it from becoming sour. When it is used, the wood becomes harder, and the growth is less succulent. Clematises are increased by cuttings of the firm side shoots in summer, placed in sandy soil in a shady place, and covered with a hand-light; but propagation by layers made now, but better in September, is a more certain method. It is now a good time to give your lawn a top-dressing of rich compost; and as its surface is wet, we would mix equal quantities of well-rotted manure, sandy soil, and ashes sifted through a half-inch sieve, and give the lawn a good dressing. The ashes will be better than the old lime rubbish, as the latter and the clay would form a sort of concrete. You may sow the seed now, rolling well afterwards; but we should wait until early next April, give another light top-dressing, and in moist weather sow Festuca duriuscula, 6 lbs.; F. tenuifolia, 2 lbs.; Poa nemoralis, 2 lbs.; Cynosurus cristatus, 6 lbs.; Poa trivialis, 2 lbs.; Trifolium repens, 8 lbs.; and T. minus, 2 lbs. These quantities are for an acre. With a north-west aspect, your external window case will not be suitable for flowering plants. It would answer best for Ferns, especially British and hardy exotic kinds. Being outside, it would only be suitable for hardy species, of which the following are desirable—viz., Asplenium marinum, Adiantum capillus-Veneris, Asplenium Trichomanes cristatum, Athyrium Filix-fœmina multifidum, Lastrea Filix-mas cristata, Polystichum angulare proliferum, Polypodium cambricum, Scolopendrium vulgare, vars. ramosum, crispum, and ramo-cristatum; Blechnum spicant cristatum, and Asplenium fontanum, surfacing with Selaginella denticulata. It would have a good effect, and be very suitable.

Shelter for a Garden (*E. R. P.*).—Poplar trees, because of quick growth, are mostly selected for affording shelter, and on that account we think they have been recommended to you. That they afford good shelter when young we know, but after they attain a considerable size they become bare at bottom and are useless as a shelter; besides, they are dull, frowning trees in winter, and are then of so little value as shelter as to be anything but desirable. A greater objection than all is their roots, which run an immense distance from the trunks and near the surface, being second only to those of the Ash in impoverishing the ground, whilst the trees, from their height, shade the ground for a considerable distance. For exposed situations, likewise, we cannot recommend them, as no trees are so liable to have their limbs blown off, and when they become old we consider them unsafe for this reason. We have removed trees from 25 to 30 feet high, and they did very well afterwards; but trees 12 feet high are quite large enough, and they are not expensive. The best time to remove them is in autumn, as soon as the leaves have fallen. We should advise a belt of Austrian Pines. They are of quick growth, evergreen, and stand wind better than most other trees; indeed, they make a better shelter than any tree we are acquainted with.

Wintering Golden-Feather Pyrethrum Cuttings (*A New Subscriber*).—We would plant out the cuttings now in a sandy soil in a warm sheltered situation, and they will stand the winter without protection;

indeed, it is quite hardy. We do not know where Achimenes atrosanguinea can be obtained.

Wintering Bedding Pelargoniums in a Pit (*C. B.*).—It is difficult to winter these plants in a pit on account of the damp, and the long period during which light and air have to be excluded in frosty weather. We should advise you to remove the sawdust, and replace it with rough ashes or gravel. For so small a pit a flue would be the most economical mode of heating, and that we would have formed along the front of the pit, having the furnace, which need not be large, at one end; 9-inch unglazed earthenware pipes would answer well for the flue inside the pit, the furnace being of fire-bricks. The joints may be made good with cement, or fire-clay if you can obtain it. The flue along the front will be sufficient. Have the elbow outside for the chimney, and do not cement that joint but mortar it, and you can remove it at any time and sweep the flue at will by pushing down to the furnace a bunch of Holly.

Skimmia oblata Propagation (*J. S. B.*).—It is not monoecious. The best stock is S. japonica, and it is sometimes worked upon that, but the majority of the plants are from cuttings or seeds. Worked on seedlings of S. japonica there can be no objection to plants of S. oblata, though we should not advise its being worked on plants from cuttings. Seedlings are stronger-growing. The plant you have of S. oblata is probably a seedling. It will grow stronger than one from a cutting, but the latter would produce berries sooner, and so would a grafted plant.

Stove Furnishing and Temperature (*Rus*).—Of plants for tubs, which we advise to be of slate, we should say you will not have room for many. Four tree Ferns would be enough:—Alsophila australis, Cibotium princeps, Cyathea dealbata, and Alsophila excelsa. Palms—Cocos coronata, Areca Verschaffeltii, A. aurea, Phœnix leonensis, Chamædorea graminifolia, and Livistonia Jenkinsii. Fine-foliaged plants—Croton pictum, variegatum longifolium, and angustifolium; Dracæna stricta and D. Cooperi; Calathea Veitchi, Alocasia metallica, Cyperus alternifolius variegatus, Dieffenbachia Pearcei, Pandanus javanicus variegatus, Theophrasta imperialis, and Cyanophyllum magnificum; Caladiums Bellemyei, Chantini fulgens, and Verschaffelti. Flowering plants—Anthurium Scherzerianum, Francisceа confertiflora, Gardenia florida, Ixora acuminata, I. javanica floribunda, Medinilla magnifica, Rondeletia speciosa major, Poinsettia pulcherrima, Cyrtoceras reflexum, Clerodendron fragrans plenum, Centradenia grandiflora, and Hoya bella. The back wall you may entirely cover with Cissus discolor, and of climbers for the roof have Stephanotis floribunda, Bignonia argyrea violescens, Passiflora quadrangularis, and P. Decaisneana. The lowest temperature should be 55° from October to February. Oranges and Figs would not do in such a house. Though the house would hold all the plants named they would soon become too large for it, especially some of the Palms and tree Ferns. "In-door Gardening" would suit you. It may be had from our office for twenty postage stamps.

Ground Vinery (*St. Dennis*).—You might leave all the Vines in your ground vinery for next season, and then only leave two, and those we would select would be Black Hamburgh and Chasselas Vibert. Most likely, as the wood is weak, you will not have much fruit next season, but the Vines will probably make good wood if well cut-in. It is of little use turning out strong, fine plants from pots, to fruit well the first season. Your plants would have fruited well in the pots; the turning them out gave them a check at a critical period, and though your canes showed fruit well, even after your thinning the bunches, the blooms refused to set. If you had merely plunged your pots, broken the bottoms a little, and top-dressed with rich manure, you might have had a good crop in the first season, but most likely you would have had to wait long for another. If you had plunged the pots after cracking the sides all round, so as to let the roots out, and taken three or four bunches from each Vine, the Vines would also have produced wood. We know we shall displease many, but still we must in fairness say that, as a general rule, a high-priced, strong, well-ripened Vine in a pot should not be planted out if fruit is expected the next season. Hence for ground vineries, we would prefer planting out only a moderate Vine as respects strength, spreading out all the roots neatly, and shortly afterwards cutting down the Vine, so as to leave only a few buds, taking no more than a bunch if it showed, and looking chiefly for a good strong single shoot the first season, to make the stem for future years. This is the surest way of going to work. The Vines taken up may be potted, but they will do little good the first season, so far as fruiting is concerned.

Sloping Bank (*A Lady in Cheshire*).—We are sorry that after attempting to revive the blooms and the little bit of shoot sent we have failed to do so. Most likely the plant is some kind of Lysimachia or Verbascum; but the specimen is too far gone, and too small, to enable us to say. For your sloping bank of grass facing the south, 4 feet high, nothing will be better than the grass; and though that is annually burnt up, this evil might be avoided by greater depth and richness of soil. The idea, however, of having Roses on a trellis is good, and if you adopt it, we would have the trellis in pieces, and hinged so as easily to reach the under side. There is, or was, such a trellis on the banks at a flower garden at the Earl of Derby's, at Knowsley. For securing continual greenness with but little trouble, and which will be little influenced by the drip from the large Birch trees, if we did not try grass again we would plant the bank with Ivy, and once or twice trimming in the twelvemonth would be sufficient to keep it neat. Of the Ivies, for this purpose we would prefer the common wild Ivy of the woods and hedges (Hedera helix) to the stronger-growing kinds, for though it would grow more slowly, it would need less attention after it had carpeted the ground. The day will come when Ivy will be more used as ground covering.

Solanum racemigerum (*An Inquirer*).—Your specimen is correctly named. It is the Currant Tomato, and we believe it to be as wholesome as the common Tomato.

Heating a Conservatory (*T. H. T.*).—If you are resolved on having a galvanised iron tank, we would dispense with coils in it, make it larger, say extending from the chimney stack as far across as not to be in the way of the door to the garden, and make it from 20 to 24 inches wide, with a division up the middle, except an open space at the farther end for the circulation; then merely take a pipe from the top of the boiler for the flow on one side, and a return pipe from the other to the bottom of the boiler. With water at 120°, that will keep your house in winter, even if the weather be rather cold, at from 38 to 45°. If you want more heat you must have more heating surface. Three 4-inch pipes—two flows and one return—would do in the place of the tank. The tank need not be more than from 5 to 6 inches deep. A foot deep, as you propose would give you a great body of water to heat, without any advantage. If you wanted more heat, the pipes might go right across the house in a trench below the level of the paths. A brick and cement tank would be more lasting than the galvanised iron. (*Dublin*).—The best mode of heating your house would have been to have taken pipes from the fireplace in the vault, having a boiler there, under your pathway. A flue would have done equally well. As you have the iron pipe, and that, as you say, becomes so hot, you might shut it in with bricks and tiles for at least part of its length next the fireplace. If it become nearly red hot it will injure plants, unless so guarded. Of course, without having a tolerably fair heat, its traversing only about one-fourth of the size of the house would be of but little benefit. The bricks and tiles would, therefore, be useful, and you could use evaporating pans to counteract the dryness. Do not think of wood; there will be danger of fire, and there will not be radiation of heat. We would now defer potting the plants you have neglected until next spring. We hope our correspondent will tell how he obtained so many flowers on the Lilium auratum. Meanwhile, let your bulb rest as soon as the leaves are yellow, and next spring top-dress with rich compost.

Forcing Mushrooms, &c. (*A Yorkshireman*).—If you had sent us a section of your barn and stable we should have known exactly what you meant. There need be no difficulty in forcing Sea-kale, Mushrooms, and Rhubarb in the same house; but if you depend on fermenting material alone for heat, and chiefly on that for preparing for Mushroom beds, there may be at times too much rank steam and moisture in the house to suit the crispness and the colour of the Rhubarb and Sea-kale. Such things without artificial heat do best when the beds are on the floor. When raised tier above tier we should not like the dung heat from a heap exposed in the house so well as a flue, as that will enable you to have dry heat or moist heat at will. We have done all you propose with a heap of fermenting dung alone, so as to keep up the atmospheric heat, and using heat, too, below the beds, but we would have preferred a flue. "Cuthill's Market Gardening" will suit you.

Mushroom Spawn (*A. B.*).—There is no known mode of procuring spawn from Mushrooms for planting. The spawn that produces Mushrooms is too far gone to be used for a similar purpose again—that is, as a general rule. The only mode of securing spawn from Mushrooms is to allow the Mushrooms to become rather old for use, and to lie and be exposed over such organic material as half-dried horse droppings, where they would spread their spores, and ultimately spread as spawn. As to procuring spawn, a heap of droppings will often produce spawn; but if you are inexperienced, the best mode for you to adopt will be to procure a bushel of spawn from a respectable nurseryman and seedsman. Perhaps, however, we do not understand the drift of your question; but we must say that besides the above, we know no other mode of obtaining spawn from the Mushroom. If we do not understand you, write again, and we shall do our best to meet your case.

Violet Culture (*A Subscriber*).—They like a situation shaded from the midday sun in summer, and we grow them on an east border, and on a north as well for succession of bloom. The soil most suitable is a good rich loam, well drained, and inclined to be sandy rather than clayey. New plantations should be made every year, using the runners of the current year, and, as soon as large enough, planting in well-dug ground, enriched with leaf soil or old cow dung. The rows should be from 15 to 18 inches apart, and the runners 1 foot apart in the lines. Water well until established, and throughout the summer they should be well supplied with water. To ward off attacks of red spider, sprinkle soot over the plants frequently in summer, which will much invigorate them. Keep them clear of weeds, and in autumn lightly fork the soil between the rows, and give a good mulching of leaf soil. You can hardly fail to have an abundance of flowers in spring. Two years are as long as the plants should remain.

Evergreen for Side of Bay Window (*A Subscriber*).—Ceanothus thyrsiflorus and Escallonia macrantha are fine; the former has blue, and the latter red flowers, and it has bright brownish foliage. Berberidopsis corallina is also fine.

Removing Oleander Flower Stems (*W. D. P.*).—The flower stems, if of this year's production, would flower again early next year if there were any buds unexpanded, as there usually are, and in that case it is wrong to remove them; but they do not always have such, yet it is a general occurrence. The finest flowers, however, are those from the well-ripened shoots of the year preceding their expansion, those from the old flower stems being useful on account of their earliness.

Climbers for Open-ground Trellis (*A Constant Reader*).—There are few evergreen climbers suitable for trellises in the open ground. We do not know of any but the Ivies and the Evergreen Honeysuckles, and the latter are only partially evergreen. All or most of the evergreen climbers require walls with south or south-west aspects. The following would be suitable:—Jasminum nudiflorum, Lonicera Periclymenum belgicum, and the Early White and Late Red; L. sempervirens Browuii and Shepherdi; Clematis Flammula, florida plena, montana grandiflora, Jackmanni, Vitalba, hybrida splendida, Viticella, and Helena; Ampelopsis quinquefolia, and Roses of the Ayrshire family—Alice Gray, Dundee Rambler, Myrrh-scented, Queen of the Belgians, Rues, and Thoreshyana, and of the Hybrid Climbing—Rivers' Queen, The Garland, Wells' White, and of the evergreen—Felicité Perpetuee, Princesse Louise, and Rampant. All are of free, rapid growth, and speedily cover a large extent of trellis, being fine flowering plants, except the Ampelopsis (Virginian Creeper).

Celery Infested by Fly (*Hordnip*).—The leaves sent are infested with the larvæ of the Celery fly (Tephritis onopordinis). We are not aware of a remedy. Pick off the leaves attacked and burn them, and when the foliage is wet dust it with dry soot. We find that by dusting the leaves earlier in the season, before the eggs are laid, the attacks of the leaf-miner are prevented. The eggs are laid from the middle of May to the end of July, but it is generally in the latter month that the autumn-brood eggs are deposited. It is enough to remove the part with the blister. (*C. B. R.*.—From your description we should say your Celery leaves were blotched and spotted brown from the attacks of the Celery fly, which is unusually prevalent this season. The only remedy is to pick off the spotted leaves, and either crush or burn them. The maggots you find are the larvæ of the Celery fly. See the above answer, also "Doings of the Last Week," page 289.

Eucalyptus globulus (*A. S——h*).—This highly-ornamental and fast-growing tree is, as you state, now extensively planted in the walks and squares of Florence, and we are of opinion that it and some other species

would endure our winters in the open air on the coasts of Devon and Dorset. Sir Joseph Paxton has recorded that "of those which have succeeded in the open air in the warmer counties of England, Eucalyptus robusta, piperita, and rotunda may be particularly mentioned; the two former flourish and grow vigorously in the Isle of Wight, where, in the neighbourhood of both Cowes and Newport, we saw plants in 1843, seedlings of but a few years old, which had already attained 20 feet or more high. They had stood two winters in the situations they then occupied, and had sustained no injury."

Moving Miniature Fruit Trees (*Amateur*).—If some of the leaves are becoming yellow you may transplant the trees at once.

Supplement to the Cottage Gardeners' Dictionary (*W. D.*).—A supplement was published last year. You can have it post free from our office if you enclose twenty stamps with your address.

Pansy Leaf Variegated (*Beckenham*).—It is not uncommon for Pansies to have their leaves variegated with yellow, but their value is not increased by it. The cause of variegation is obscure, but you will see it discussed at considerable length when the variegated Pelargoniums were under consideration, in our thirteenth volume.

Oak Lodge.—In Mr. Keane's report on Oak Lodge (see page 281), he wrote by mistake Eucharis magnifica. It should have been Medinilla magnifica.

Select Show Dahlias (*A Subscriber*).—The following are distinct and good:—Charlotte Dorling, Lord Derby, Leah, Chairman, Clara Simons, Harriett Tetterill, Uniquo, Fanny Purchase, Lady Gladys Herbert, Paradise Williams, Earl of Pembroke, John Wyatt, James Backhouse, Earl of Shaftesbury, Bob Ridley. Flag of Truce, Criterion, Andrew Dodds, Princess of Wales, Purity, Fair Imogene, Chairman, Lilac Queen, Donald Beaton, Flambeau.

Abnormal Primula Seedling (*R. Maries*).—It is the most striking variation we have ever seen. The flower is enclosed in a green calyx much larger than the corolla, and when first seen looks like a Primula embosomed in a much-cupped Pelargonium leaf.

Names of Fruits (*Pomona*).—Your Pear was named in our Journal of September 2nd. It was Williams's Bon Chrêtien. (*B. Chadwick*).—1, Wormsley Pippin; 2, Hollandbury; 4, Red Doyenné. (*D.*)—Flemish Beauty. (*H. J. C.*).—*Figs*: 1, Célestine; 2, Brown Turkey; 3, Brunswick. *Pears and Apples*: 1, Comte de Lamy; 3, Napoleon; 4, Van Mons Léon Le Clerc; 6, Beurré Clairgeau; 7, Van Marum; 8, Thompson's; 9, Winter Bon Chrêtien; 10, Red Winter Calville; 12, Blenheim Pippin.

Names of Plants (*J. R. Boyd*).—The fragment of the plant sent us is insufficient for determination; it is certainly Amaryllidaceous. Send when in bloom, and we will endeavour to assist you. (*Nanny*).—1, Apparently Monopsis debilis, but certainly one of the Lobeliaceæ; 2, Specimen too fragmentary. (*M. R. Crosby*).—1, The common curled Mallow, universally cultivated in gardens; 2, Adiantum fulvum; 3, Cheilanthes elegans. (*J. S. T.*).—1, Pteris cretica albo-lineata; 2, Trichomanes, specimen insufficient to say what species; 3, Gymnogramma chrysophylla; 4, Pellæa adiantifolia; 7, Selaginella hortensis, more correctly known as S. Kraussiana; 8, Pteris longifolia; 9, Eranthemum rubronervium; 10, Fittonia argyroneura. (*C. L. W.*).—Leucadendron argenteum. Treat it as a greenhouse plant. (*R. H.*).—1 and 5, Asplenum Adiantum-nigrum in different stages; 2, Asplenium marinum; 3, Polypodium vulgare; 4, Doodia caudata; 6, Adiantum capillus-Veneris. (*Agg.*—1, Echium vulgare; 2, Saponaria officinalis; 3, Verbascum nigrum. (*E. A.*).—1, Cheilanthes farinosa; 2, Pellæa geraniifolia; 3, Asplenium furcatum; 4, Pteris semipinnata; 5, Hemionitis cordata; 6, Gymnogramma barbarea; 7, Cincinalis flavens, otherwise Nothochlæna chrysophylla; 8, Asplenium, an insufficient specimen; 9, Gymnogramma peruviana argyrophylla; 10, A forked variety of the last; 11, Adiantum æthiopicum; 12, Adiantum tetraphyllum; 13, Rhipsalis salicornoides; 14, Phymatodes lineare; 15, Selaginella Kraussiana. (*A Sussex Lady*).—The common Hornbeam, Carpinus Betulus. (*Mrs. M., Bitteswell Hall*).—We cannot name plants from their leaves only, we must see the flowers. (*Novice*).—The flower is Fuchsia corymbiflora. The other, being a leaf only, we cannot name.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending October 12th.

Date.	Barometer.		Thermometer.				Wind.	Rain in inches.	General Remarks.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.

POULTRY, BEE, AND PIGEON CHRONICLE.

AUCTION AT THE BIRMINGHAM EXHIBITION.

I observe that the sale of prize birds at the next Birmingham Show is again fixed for 11 o'clock A.M., on Monday, the 29th of November. That time for persons who, like myself, reside at a distance from Birmingham, is most inconvenient—in fact, gives us no chance of purchasing, if we be so inclined. If you can in any way be the means of getting the sale postponed for, say, two hours, you would, I feel sure, be conferring a favour on many others as well as myself, and the show would, I imagine, reap the benefit of additional commission.—Robert B. Wood, *Staffordshire*.

EXHIBITING BORROWED BIRDS.

I know for a certainty that many gentlemen, not conscientious ones, borrow birds to exhibit at different shows. This is giving a poor chance to those who *bonâ fide* show their own. Is there no way by which such fraudulent offences could be prevented? I think every exhibitor should make a declaration that the birds are his own property, and that this declaration should be given to the Secretary on the day of the show, and if an exhibitor is detected showing birds not his own he should not be allowed to enter at that place again, and no prize should be given to his birds.—J. G. M.

CUP FOR HOUDANS AT THE NEXT SOUTHAMPTON SHOW.

The following are the subscribers:—Mrs. Wilkin, 5*s.*; "A Lady fond of French Fowle," £1 1*s.*; Mr. H. M. Maynard, £1 1*s.*; Mr. W. Dring, 5*s.*; Mr. O. Quibell, 5*s.*; Mr. F. Brewer, 2*s.* 6*d.*; Mr. P. P'Anson, 5*s.*; Mr. H. S. Fraser, £2 0*s.* 6*d.*—Total £5 5*s.*

Prolific Game Pullet.—Mr. James Balmair, of Bolam West House, Northumberland, has a Game pullet in his possession which was hatched on the 28th of February last, laid her first egg on July 15th, has laid forty-six eggs, and hatched seven chickens by September 24th; or laid her first egg when 137 days old, laid forty-six eggs, and sat for her own hatching in seventy-one days.—G. W. W.

LONG SUTTON POULTRY SHOW.

That this Show annually improves both in interest and arrangement there can be no dispute. A marked feature of the Show is, that those breeds most needed for the table are the best supported. A very liberal prize schedule, as usual, brought on the 6th and 7th inst. an equally liberal entry, and but for the simple fact that about sixty pens of birds arrived several hours too late for competition, the Show would have been far in advance of any of its predecessors. The folly we have so frequently pointed out of leaving birds for transit by the last possible train was thus again exemplified.

The *Dorkings* were mostly in deep moult, but the majority of them were of first-class character. The bulk of the *Cochins* were, on the contrary, in excellent plumage, and consequently an advantage in general competition ensued, as *Brahmas*, *Dorkings*, and *Cochins* competed in general for the cup prizes. *Hamburghs* were remarkably good—in fact, far better than they have been shown on any previous occasion in this locality. In connection with these a very singular circumstance transpired—an exhibitor had written beforehand to the Committee, or rather Secretary, stating his perfect willingness, if successful, to send £1 and a new hat or two to the Secretary, if he would draw the attention of the Judge to these particular pens. From their indisputable excellence the priority of position was given these fowls, as at a meeting held the previous evening the Committee thought fit not to disqualify them, though, as then stated by the Judge, had the missive borne his direction they would have been thrown out of competition at once. We sincerely hope such practices will not be again attempted. The *Polands* were very good, and the *French* fowls far superior to those seen at the generality of poultry shows.

The Aylesbury *Duck* and *Geese* classes were such as are but rarely met with, and a pen of first-class Sebastopol Geese are worthy of especial note. A class for ornamental birds of any variety, or any number in a pen, caused a severe competition. It proved one of the most attractive features of the Show.

All the *Pigeons* were of high excellence—in fact, so good a competition is very rarely met with, and the collection of *Rabbits* was considered as not less praiseworthy. Every possible care was bestowed on the

birds committed to the care of the managers of the Show, and we are glad to say that, favoured with exceedingly fine weather, the meeting was most successful.

DORKING (Any variety).—*Cock.*—1, H. Lingwood, Barking, Needham Market. 2, O. E. Cresswell, Hanworth Rectory, Hounslow. *hc*, L. Patton, Hillmore, Taunton. *Hens or Pullets.*—1, G. Clarke, Long Sutton. 2, T. E. Kell, Wetherby. *hc*, H. Savile, Ollerton; C. Clarke; D. White; H. Lingwood; L. Patton; J. Elgar, Osmanthorpe Hall, Newark (Silver-Grey).

COCHIN-CHINA (Any variety).—*Cock.*—Cup, T. H. Radman. 2, C. Sidgwick, Ryddlesden Hall, Keighley. *hc*, J. K. Fowler, Aylesbury (Partridge). *c*, A. Williamson, Queniborough Hall, Leicester (White). *Hens or Pullets.*—Cup, H. Lingwood (Buff). 2, T. M. Derry (Partridge). *hc*, C. Sidgwick; Mrs. J. Clarke (White); W. A. Burnell, Southwell, Notts (Buff; J. Cattell, Bingham; A. Williamson (White). *c*, S. S. Mossop (Buff); F. F. Anderson (Buff); T. M. Derry (Partridge); J. K. Fowler (Partridge).

BRAHMA (Any variety).—*Cock.*—1, Rev. E. Alder, Etwall Vicarage. 2, H. Savile (Light). *Hens or Pullets.*—1, Rev. E. Alder. 2, H. Savile (Light). *c*, Rev. E. Alder; W. Whitley.

SPANISH (Any variety).—*Cock*—1, Withheld. 2, H. Beldon, Goitstock, Bingley. *Hens or Pullets.*—1, T. & E. Combar, Myddleton Hall, Warrington. 2, F. James. *hc*, H. Beldon.

HAMBURGH (Gold or Silver-spangled).—*Cock.*—Cup, S. S. Mossop (Silver). 2, J. & R. Ashton, Mottram (Golden). *hc*, W. K. Patrick (Golden-spangled); J. Laming; H. Snushall. *c*, T. Walker, jun., Denton. *Hens or Pullets.*—Cup, T. Walker, jun. 2, S. S. Mossop (Silver). *hc*, D. Lord; J. Laming; H. Snushall. *c*, J. Walker.

HAMBURGHS (Gold or Silver-pencilled).—*Cock.*—1, S. Burn (Gold). 2, S. S. Mossop (Silver). *hc*, R. R. Parker (Gold). *c*, J. Walker; A. Cole (Gold). *Hens or Pullets.*—1, J. Laming. 2, A. Cole. *hc*, J. Walker; S. S. Mossop (Silver).

GAME (Black-breasted or other Reds).—*Cock.*—Cup, T. C. & E. Newbitt. 2, R. Hall, Cambridge (Brown Red). *hc*, Rev. T. O'Grady, Ashbourne. *c*, H. Snushall (Black Red). *Hens or Pullets.*—Cup, H. Mason (Red). 2, Hon. C. Fitzwilliam, Wentworth Woodhouse (Brown Red). *hc*, Rev. T. O'Grady; W. Boyes, Boverley; W. J. Popo (Black Red); J. Longbottom. *c*, H. Snushall.

GAME (Any other variety).—*Cock.*—1, H. Beldon. 2, T. Dyson, Halifax. *Hens or Pullets.*—1, H. Beldon. 2, J. Longbottom. *hc*, H. Mason (Duckwings). *c*, G. Leo (Duckwings); W. Boyes (Duckwings).

GAME BANTAMS (Black-breasted Reds).—1 and 2, W. T. Entwisle, Leeds. *c*, J. Crosland, jun., Wakefield. *c*, J. W. Morris, Rochdale.

GAME BANTAMS (Any other variety).—1, H. Shumach, Southwell. 2, R. B. Riley (Duckwing). *hc*, J. Crosland, jun. (Duckwing). *c*, J. Dring (Duckwing)

BANTAMS (Black or White). — Cup and 2, S. S. Mossop (Black). *c*, Hudson & Burnip (Black); A. Stonar (Black); J. Longbottom (Black).

BANTAMS (Any other variety).—1, A. Hodson (Gold-laced). 2, J. White (Pekin). *c*, H. S. Hunt (Japanese Silkies); T. C. Harrison, Hull (Laced); Mrs. Woodcock (Japanese); H. Draycott, Humberstone, Leicester; S. H. Stott, Rochdale (Japanese).

ANY OTHER DISTINCT VARIETY.—1 and 2, Mason & Walker, Denton (Black Hamburghs). *vhc*, S. S. Mossop (Polands); Hon. C. Fitzwilliam (La Flèche). *hc*, C. Sidgwick (Black Hamburghs); W. K. Patrick (Polands); Mrs. E. Cross (Crêve-Cœurs); J. J. Maldon (Crêve-Cœurs); J. Holt (Black Hamburghs); J. T. Ashley (Minorcas); J. Laming; J. K. Fowler (Crêve-Cœurs); H. Savile (Andalusians); J. S. Senior (Polands).

ORNAMENTAL BIRDS (Any breed).—1, J. Mayes (Gold Pheasants). 2, H. Savile (Silver Pheasants). *vhc*, J. K. Fowler (Kaleege Pheasants). *hc*, W. Woodhouse (Goldfinch Mules); G. E. Storr (King Parrot); J. Mayes (Silver Pheasants); W. Lamb (Java Sparrow); G. Clarke (Golden and Common Pheasants); Lord Manchlin (Assyrian Partridges). *c*, T. C. Harrison (Pintail Ducks).

TURKEYS (Any variety).—1, W. Sunday. 2, M. Kew (Cambridge). *hc*, J. B. Bides; Mrs. E. Harris (Cambridge); T. M. Derry (Cambridge).

DUCKS (Rouen).—1 and *c*, W. H. Robson. 2, L. Patton. *hc*, J. A. Clarke; J. K. Fowler; S. H. Stott; J. Wright.

DUCKS (Aylesbury).—1, Mrs. M. Seamone, Aylesbury. 2, J. K. Fowler. *hc*, W. Stonehouse.

DUCKS (Any other variety).—1, T. C. Harrison (Mandarins). 2, A. & J. P. Trickett (Carolinas). *hc*, H. Beldon; A. & J. P. Trickett (Porchards). *c*, T. C. Harrison (Carolinas); Mrs. Cross (Widgeon); S. & R. Ashton (Carolinas); J. H. Roper (Carolinas).

GEESE (Any variety).—1, J. K. Fowler. 2, E. Leech, Rochdale. *hc*, Rev. G. Hustler, Stillingfleet Vicarage, York (White and Grey Toulouse); J. T. Ashley; Mrs. Seamone; H. Savile (Sebastopol); S. H. Stott.

SELLING CLASS (Any variety).—1, T. M. Derry (Partridge Cochins). 2, J. K. Fowler (Aylesbury Ducks). *hc*, Mrs. J. Clarke (White Cochin); T. M. Derry (Partridge Cochin). *c*, J. A. Clarke (Rouen Ducks); G. Boyes (Black-breasted Game); Dr. D. C. Campbell (Dorkings); G. Clarke (Dorkings); J. Barnes (Game Bantams); *c*, A. Cole (Spanish).

SELLING CLASS.—1, W. K. Tickner (Gold-pencilled Hamburgh). 2, H. Beldon. *c*, S. S. Mossop (Black Bantams).

LOCAL PRIZES.—*Classes* 1, 3, 5, 7, 9, 11, 13, and 15.—Cup and 2, S. S. Mossop (Silver-spangled and Pencilled Hamburghs). 3, H. Snushall Spangled Hamburgh). *Classes* 2, 4, 6, 8, 10, 12, 14, and 16.—Cup, G. Clarke (Dorkings). 2, T. M. Derry (Partridge Cochin). 3, S. S. Mossop (Silver-spangled).

BANTAMS, OR ANY OTHER VARIETY.—Cup, 2, and S, S. S. Mossop (Black (Bantams and Polands).

PIGEONS.

CARRIERS (Black).—*Cock.*—1 and 2, R. Fulton, Deptford. *hc*, R. Fulton; F. Crossley, Elland. *Hen.*—1 and *hc*, F. Crossley. 2 and *c*, R. Fulton.

CARRIERS (Any other colour).—*Cock.*—Cup, J. C. Ord. 2, R. Fulton (Dun). *hc*, R. Fulton (Dun); T. H. Frean (Dun); F. Crossley (Dun). *Hen.*—1, R. Fulton. 2, J. C. Ord. *hc*, R. Fulton; J. C. Ord; F. Crossley (Dun).

POUTERS (Red or Blue).—*Cock.*—1, F. Crossley (Blue). 2, R. Fulton. *hc*, J. Taylor; R. Fulton. *Hen.*—1, 2, and *hc*, R. Fulton.

POUTERS (Any other colour).—*Cock.*—1 and 2, R. Fulton. *c*, J. Taylor; P. H. Jones, Fulham (Yellow). *Hen.*—1 and 2, R. Fulton. *hc*, W. R. Rose (White).

TUMBLERS (Almond).—Cup, T. Wiltshire. 2, R. Fulton. *hc*, J. H. Ivimy; R. Fulton. *c*, T. Wiltshire; J. Fielding.

TUMBLERS (Any other colour).—1, W. Woodhouse (Beard). 2, R. Fulton (Short-faced). *hc*, J. H. Ivimy (Yellow Agates); R. Fulton (Mottled and Red). *c*, F. Crossley.

JACOBINS.—1 and 2, R. Fulton. *hc*, G. South. *c*, E. E. M. Royds, Rochdale.

FANTAILS.—1, W. H. Tomlinson (White). 2, H. Yardley, Birmingham. *hc*, W. H. Tomlinson (White); J. Spence (Black); H. Yardley; T. C. & E. Newbitt, Epworth.

OWLS.—Cup, F. Crossley. 2, J. Fielding, Rochdale.

TURBITS.—1, P. H. Jones. 2, R. D. Borne, jun. (Blue). *hc*, O. E. Cresswell (Red); P. H. Jones; J. Fielding, jun. *c*, Hudson & Burnip (Red).

BARBS.—1, R. Fulton. 2, F. T. Wiltshire. *hc*, R. Fulton; F. Crossley. *c*, W. Massey.

DRAGOONS.—1, G. South. 2, H. Beldon. *hc*, T. Wiltshire; R. Fulton; T. H. Frean.

ANY OTHER DISTINCT VARIETY.—1, H. Yardley. 2, H. Draycott (Red Swallows). *hc*, H. Beldon; H. Yardley; H. Draycott (Frillbacks); J. Cox (Magpies). *c*, T. H. Frean (Silver-laced Fans and Magpies); Hudson and Burnip (Blue Magpies).

SELLING CLASS.—1, F. Clarke (White Jacobins). 2, E. Walker (Carriers). *hc*, H. Beldon; T. H. Frean (Fantails). *c*, E. Walker (Pouters); R. D. Borne, jun. (Sandy Antwerps); Mrs. Woodcock (White Trumpeters); J. C. Ord; S. & R. Ashton (Archangels); W. Massey (Carriers); R. F. Payling (Yellow Turbits).

RABBITS.—*Any Pure Breed.*—1, B. Hudson. 2, A. H. Easton (Lop-eared Tortoiseshell Doe). *hc*, S. G. Hudson (Silver-Grey Buck); J. J. Stott (Tortoiseshell Doe). *c*, S. Hardcastle; J. G. Quick (Lop-eared); C. King (Fawn Buck). *Heaviest.*—1, W. Kitchen. 2, W. Jeffray (Black and White Doe). *hc*, P. Booth (Sandy and White Doe). *c*, J. Pearson (Tortoiseshell Doe); H. Frith (Black and White Doe).

The Judges were—for *Poultry*, Mr. Edward Hewitt, of Birmingham; for *Pigeons*, Mr. Tegetmeier, of London; and for *Rabbits*, Mr. Massey, of Spalding.

CHELMSFORD POULTRY SHOW.

THIS Show, held on the 12th and 13th inst., was highly successful, there being upwards of 450 entries of poultry and Pigeons. Annexed is the prize list, but we must defer further details till next week.

DORKING (Coloured).—*Cockerel.*—1, L. Patton, Bishop's Hull. 2, J. Smith, Shillinglee, Petworth. 3, Dr. Campbell, Brentwood. *c*, Dr Campbell; H. Dowsett, Pleshey, Chelmsford; F. Parlett, Great Baddow. *Pullets.*—1, L. Patton. 2, Mrs. E. Wheatley, Ingatestone. 3, Dr. Campbell. *hc*, J. H. Roper, Barham, Claydon.

DORKING (Any other variety). — *Cockerel.* — 1, R. W. Richardson, Beverley, Yorkshire (Silver-Grey). 2, O. E. Cresswell, Hanworth, Hounslow. *Pullets.*—1, O. E. Cresswell. 2, Dr. Campbell (Silver-Grey). *hc*, C. Turner, Chelmsford (Silver-Grey).

GAME (Black-breasted and other Reds).—*Cockerel.*—1 and 2, Rev. F. Watson, Kelvedon, Essex (Brown-breasted Red). 3, W. C. Phillips, Worcester (Black-Red). *Pullets.*—1, S. Matthew, Stowmarket. 2, D. Ashworth, Halifax. 3, J. Jeken, Eltham, Kent. *hc*, Rev. F. Watson (Brown-breasted Red). *c*, J. Longbottom, Halifax.

GAME (Any other variety).—*Cockerel.*—1, T. Dyson, Halifax (Duckwing). 2, J. Brasington, Dresden, Stafford (Duckwing). 3, J. TRUMPETERS.—1, P. H. Jones. 2, E. Sheerman. *hc*, J. J. Hazell, Great Bromley; E. Sheerman. *c*, Mrs. Paget.

ANY OTHER VARIETY.—1, P. H. Jones (Turbits). 2, H. Draycott (Frillbacks). *hc*, Lady F. Bushby, Henleage, Kingston Hill (Blue Runts); S. A. Wyllie (Ice); Mrs. Paget (Owls and Ice). *c*, S. A. Wyllie (Runts).

JUDGES.—E. Hewitt, Esq., Sparkbrook, Birmingham, and W. B. Tegetmeier, Esq., Muswell Hill, London.

WETHERBY POULTRY SHOW.

THIS Show was held on October 1st, and in most respects was a success. The *Geese* and *Turkeys* were large and good, and the *Spanish*, especially the chickens, very fine. The *Dorkings* were, however, the leading feature of the Show, and were all that could be desired as regards size, colour, and quality. *Game* were poor. The winning *Hamburghs* were better. Some very good *La Flèche* and *Crève-Cœurs* were shown; also Golden-laced and Black *Bantams*, though the Game were not quite so high in quality. There was a handsome pair of White Angora *Rabbits*.

COCHINS.—1, W. & F. Pickard, Thorner. *Chickens.*—1, G. Duffield, Thorner.

SPANISH.—1, W. & F. Pickard. *Chickens.*—1, W. & F. Pickard. *hc*, J. Cook, Bishop Wilton.

DORKINGS.—1, T. E. Kell, Wetherby. 2, O. A. Young, Driffield. *hc*, T. E. Kell. *Chickens*—1, 2, 3, and *hc*, T. E. Kell.

GAME.—1, J. Watson, Knaresborough. 2, T. Hawkes, Hunsingore. *hc*, E. Birkenshaw, Wetherby. *Chickens.*—1, J. Walker. 2, T. Hawkes. *c*, T. Ridsdale, Kirkby Overblow.

POLANDS.—1, T. Crossley, jun. *Chickens.*—1, W. & F. Pickard.

HAMBURGHS (Golden).—1, J. Walker. *Chickens.*—1, J. Walker. 2, J. Margerison, Collingham. *Silver.*—1, J. Walker.

HAMBURGHS (Pencilled).—1, O. A. Young. *Chickens.*—1, J. Walker.

BARNDOOR OR CROSSBREED.—1, O. A. Young. 2, Mrs. Gunter. *Chickens.*—1, Mrs. Gunter.

ANY OTHER DISTINCT BREED.—1, J. Walker (Black Hamburghs). 2, J. Dyson, Wetherby. *Chickens.*—1 and 2, Mrs. Price, Aberford (La Flèche and Crève-Cœur).

BANTAMS.—*Silver or Gold-laced.*—1, O. A. Young. *Black.*—1, J. Walker, Haya Park. *Any other Variety.*—1, T. C. Taylor, Ontlands. 2, J. Walker (Game). *Chickens.*—1 J. C. Taylor. 2, O. A. Young.

GEESE.—1 and *hc*, Lord Wenlock. 2, O. A. Young. *c*, J. Simpson, Spofforth Park.

DUCKS.—1, Mrs T. E. Kell (Carolina). 2, W. Burley, Wetherby. *Ducklings.*—1, O. A. Young.

TURKEYS.—1, O. A. Young. 2, Mrs. Gunter.

The Judge was Mr. E. Hutton, Pudsey, Leeds.

RABBITS AND THEIR JUDGES.

MR. JAMES DIXON, in your last number, takes me to task for certain remarks I had made on the so-called judging of Rabbits at the Whitby Show; but at the same time, knowing that I was only "*one of many* witnesses," he discreetly takes care not to deny one single statement I advanced. He has done something easier—he has replied illogically and transparently evasively.

Take Mr Dixon's first remark. He quotes the following words of mine quite correctly—"The Judges positively got through (I do not say judged), twenty-one Rabbits in a trifle short of two minutes," and then he immediately adds, "instead of there being twenty-one pens, there were only eleven. Fourteen pens were entered, and three, I think, were empty." Now, if this is not creating a General on purpose to kill him, I do not know what is. Mark this—I said nothing about pens, even according to his own quotation of my words. I said twenty-one Rabbits, and this I adhere to, and yet Mr. Dixon would lead any hasty reader to suppose I had made a gross mis-statement. Many of the pens held pairs (which I mentioned with disapproval in another part of that letter); but I suppose even Mr. Dixon will not deny that he has to judge of each individual Rabbit before he decides which two make the best pair, so that my charge that the Judges got through twenty-one Rabbits in the preposterously short time of less than two minutes remains unshaken. For, be it observed, he does not deny that I am right as to time. Mr. Dixon simply wants to convey the impression to your readers that he only had eleven Rabbits to judge, and therefore that the time was sufficient, though he would fail to make any Rabbit-fancier believe in such an absurdity.

Further on, Mr. Dixon makes a remark which I had to read three times over before I could believe my eyes. He says, "Had there been a large entry, of course we should have measured them." I verily had always thought it to be the manifest duty of a judge to conscientiously balance the merits of the specimens submitted to him, let them be few or many, and, indeed, any plain man would say it was all the more inexcusable if there were few not to devote the necessary time, and use the necessary means to ascertain which was best, as the task would be so much lighter. If this is to be understood as the doctrine of the Judges, they will soon lessen the entries with a vengeance.

Mr. Dixon remarks, "He does not say that the prize was not given to the best Rabbit, but that we certainly did not know, and as clearly did not care. These remarks are quite uncalled for, unless he could show that we had erred in judging, which I am quite sure we did not." In answer to this, I would say that I had no narrow views in writing that letter, but took the matter up in justice to the fancy generally. As, however, Mr. Dixon makes the assertion that the Judges did NOT err in judging, I meet that bare assertion with a flat contradiction, supported as I was in my opinion by nearly a dozen experienced Rabbit fanciers, some of whom had often been judges themselves, and among whom there was not the least difference of opinion as to which was the best Rabbit, and we had spent an hour among the Rabbits before the Judges came round to spend their less than two minutes. The Rabbit pronounced best at Whitby was at Long Sutton last Wednesday (Oct. 6), but took no prize, while the one coming second at Whitby took first at Sutton, as "Best of any breed;" but the Committee there had very properly engaged a special judge for Rabbits. If, however, Mr. Dixon and his colleague will endeavour to have the two Rabbits brought together and judged by two real Rabbit judges unknown to either of us (as might possibly be feasible at Leeds or York, next December), I will gladly, if proved to be in the wrong, pass £5 through your hands to any charity that you may think most deserving of support.—ONE OF MANY WITNESSES.

SPURIOUS HONEY AND FRAUDULENT BEE-KEEPERS.

SOME time ago a correspondent asserted in your columns that the Stewarton hive produced the finest honey in the world, an assertion rather too extravagant for your intelligent readers, for they well know that neither the shape nor material of a hive can improve the quality of the honey it may contain. I am not in this letter going to say one word for or against the Stewarton hive; I wish merely to lift my voice against a fraudulent practice of some bee-keepers in Scotland, and perhaps some in England too.

A few days ago there came from Glasgow to Manchester three Stewarton hives, supers full of beautiful comb—doubtless the gift of some gentleman in Glasgow to three of his friends here. It was my good luck to taste the honey or syrup those supers contained; I say syrup, for it was nothing more nor less than sugar and water which had been given to the bees and stored up by them. I remember some honest bee-keepers in Lanarkshire, some years ago, expressing their wonder to me how the Ayrshire men managed to send to the Glasgow market so

early in the season those shallow boxes of honeycomb which they saw offered for sale in the shops. They never dreamt that the simple process of mixing sugar and water left them so far behind; I could not understand it myself till I tasted the honey mentioned above. Sugar costs 4½*d.* per lb. and requires 1 lb. of water to make good syrup for bees, thus the syrup costs about 2¾*d.* per lb. How much weight is lost in the manufacture of comb I cannot accurately say, neither can I tell what price the manufactured comb sells at; doubtless there is considerable profit. It matters not to me whether 6*d.* or 1*s.* 4*d.* per lb. he realised; but unhesitatingly do I condemn the practice as dishonest, for sweetened water never becomes honey, even though it be twice swallowed and disgorged by bees. It is dishonest to knock a man down with a view to steal his purse; it is as dishonest to take the purse without the knock-down, and the trick of selling syrup for honey is equally dishonest, unless the buyer be told that the honeycomb is spurious, or artificially made. If the trick be not exposed, and the practice put an end to, the day will soon come when it will be difficult to sell genuine honey and honeycomb. I shall be glad if the honey merchants of Glasgow see these remarks, and taste the honey in the comb before they venture to purchase it; and judges of honeycomb at the agricultural shows would do well to taste the honey before they award the prizes. One bee-keeper crossed the border to a northern English town, and for three or four years in succession carried back the prizes given for honeycomb. He told a friend, who told me, that sugar and water enabled him to win the prizes.

It does not follow that, though some of the Stewarton hives are made use of for purposes of deception, all are. Doubtless many of the Ayrshire bee-keepers use them honestly and well for the collection of pure and unadulterated honey.—A. Pettigrew, *Rusholme, Manchester.*

MANAGEMENT OF BEES.

I am puzzled at the statements relative to the treatment of bees, from which, until enlightened as to the line of procedure, we should imagine they were as harmless as flies and did not possess stings, whereas they are very pugnacious and not to be trifled with. One is surprised to learn that the interior of hives is examined, queen bees taken out, other queens put into the hive, combs that are cracked made straight, part of the honey taken out, and bees transferred from one hive to another, without any apparent difficulty. One person asserted that in October he removed the bees from a hive full of honey to an empty hive, took all the honey (not fair dealing), and fed the bees with sugar and water, from which they soon stocked the hive with combs and honey; but he does not say how he effected the transfer of the bees from hive to hive. I have been told that bees will not by driving be made to quit a hive filled with honey for one which has none. I wish to remove the bees of one hive into another which has numerous improvements, and should be obliged if yourself, or any of your correspondents, will kindly inform me the best way of doing this. I presume if the comb and honey taken from the one hive is put upon the floor-board of that into which the bees have been removed, it will greatly aid them in stocking the hive.—Inquirer.

[A skilled bee-master does with the aid of frame hives, really treat his bees pretty nearly as if they were as harmless as flies, and you are by no means the first who has been puzzled as to how it is done. Example is in these cases so much more effectual than precept, that if you will send us your address we will endeavour to introduce you to the nearest master of the art with whom we happen to be acquainted, and would advise your not grudging a moderate journey in order to witness his manipulations. In the meantime, we reprint the following advice given by Mr. Woodbury in reply to a correspondent who, in 1862, found his bees like your own, very pugnacious and not to be trifled with. "'A. W. B.' does not appear to have done so much amiss for a first attempt. He obtained what he wanted, which is a great point, but he appears to have mortally offended his bees. Had the matter been managed more adroitly they would have manifested a much more forgiving spirit. Let him by all means envelope himself in a bee-dress, and arm himself with his lighted fumigator; but in mercy to himself and his bees exchange his buckskin for indiarubber gloves, such as are worn by photographers, and take with him a sop for Cerberus in the shape of some sweetened water. Commence proceedings by slightly raising the crown-board at the back, and blowing under it two or three good whiffs of smoke; then close it down, and wait a minute or two while the bees are filling themselves with honey. Next lift it boldly off, and stand it safely on one side, so as not to crush any bees which may adhere to it, and liberally sprinkle the interstices between the exposed bars with sweetened water. Should the bees take this in good part without commencing an attack the operation may be at once proceeded with; but if their pugnacity be not quite subdued a second subsidy of sweets should be accorded them, and the crown-board replaced for a few minutes to give time for their acceptance of the proffered bribe. All these manipulations are based upon the fact that when bees are alarmed they immediately fill themselves with honey, or such other sweets as may be at hand, and that if we can once induce them to do this they become as inoffensive as house flies. No provocation short of absolute crushing will induce them to sting." There is no difficulty whatever in driving bees from a full hive into an empty one in the manner described in page 60 of the last edition of "Bee-keeping for the Many;" but it would be a miserably bungling attempt at assisting them if you placed the contents of their old domicile higgledy-piggledy on the floor-board of their new one. A satisfactory transfer can in point of fact scarcely be effected except into a frame hive in the manner described in page 72 of our present volume. If, therefore, frames are not among the numerous improvements appertaining to your new hive, we should advise its remaining unoccupied until it can be stocked by a swarm in the usual manner.]

OUR LETTER BOX.

Chickens not Thriving (*Norice*).—As a rule, this is the time of year when fowls require watching, and when a little alteration in food by way of stimulant is very beneficial; but it has been so warm, that such treatment would be superfluous. Are they in a damp place? Is the diminution of the hours of sunshine felt? We advise you to do away with the buckwheat, the sharps, and the potatoes. The latter may be given as a change and a help at times, but to adopt them as regular food is neither profitable to you nor wholesome for the birds. Give them some bread steeped in strong beer. When a bird seems to become worse, remove it from the others, and give it some pills of camphor, two for a dose, each the size of a pea. Give them lettuce whenever you can, cabbage when you have nothing else to give; but they will not eat lawn mowings, and they only make a mess in the pens. Quadrupeds will eat them, but fowls will only eat them when they can pick them, and they cannot pick them save when growing.

Middleton Snow.—The first prize for a Black Hamburgh cockerel, we are informed, was awarded to Messrs. Mason & Walker, and not to Mr. Charles Sidgwick.

Points of Silver Duckwinged Game Fowls (*G. D.*).—The Silver Duckwing must have no brown patch on the wings, and the feathers that are straw-coloured in the ordinary Duckwings, must be pure white in the Silvers. The hen must have no robin or wheaten breast.

Food Needed by Fowls (*H. T.*).—You do not know yourself the quantity of food the fowls gather, and we cannot, in the absence of such information, give any other than a general answer to your question. You must be guided by their consumption and feed accordingly. In warm weather like this they obtain much food from the surface of the earth. In very dry, cold, and frosty weather they find little or nothing. Now the food may be decreased, then it must be increased. The best food to give is barley, but in hard weather it is necessary to substitute Indian corn, as the small birds steal the barley. They cannot swallow the Indian corn. The best quality of food is always the cheapest, and there is none so dear as the indifferent samples that cost less money

Furnace Game Fowls (*A Subscriber*).—There are no other points that differ from any other breed of Game but the colour. You will find that in all the poultry books.

How to Distinguish a Gander (*E. R. P.*).—We have great faith in the opinions of old women when the sex of Geese is in question. They say that if Geese are put in a pigstye, shed, or other confined place, and a dog is thrown in to them, the Geese will raise their heads and withdraw, the gander will drop his head, stretch out his neck, and hiss at the dog. Others say the bag that hangs between the legs is double in the gander, single in the Goose. Some say the neck of the male is thicker and clumsier than that of the female. The sure and infallible way is to examine the bird by handling, there can then be no doubt. Pressure below the vent will reveal the sex.

Points in Partridge Cochins (*Colpe*).—The points of Partridge Cochins are the same as in others, except that the colour is different. The comb should be medium-sized, well serrated with numerous serrations, and scrupulously straight. The danger of a large comb is, that it is almost always crooked. The less yellow tinge there is in the plumage of these birds the better it is; they are prone to this defect. The cock must have a thoroughly black breast. Any mixture of buff is a disqualification.

Crève-Cœurs' Feet Distorted (*Idem*).—The Crève-Cœurs would not be disqualified, and it would only be disadvantageous in very close competition.

Weak Swarms and Stocks (*A. Crowley*).—The bees are certainly worth saving, and it will tend to prevent confusion if you unite the inhabitants of adjoining stocks. The union should be effected by driving both colonies into an empty hive, and afterwards inducting them into the domicile which they are intended permanently to occupy, as stated in reply to "M. J. V." in page 218.

Proverb (*Gallus*).—The proverb you refer to is probably the following, indicating that young specimens of the animals mentioned are preferable for table.—"Chickens chirping, Pigeons peeping, Rabbits creeping, are best eating."

WEEKLY CALENDAR.

27	W		54.9	38.7	46.8	27	46 6	41 4	53 9	9 1	22	16 4	300

From observations taken near London during the last forty-two years, the average day temperature of the week is 56.9°; and its night temperatnre 39.4°. The greatest heat was 69°, on the 22nd, 1863 and the lowest cold 17°, on the 23rd, 1859. The greatest fall of rain was 0.96 inch.

VERBENA VENOSA, AND HOW TO PROPAGATE IT.

WITH all that Mr. Robson states respecting Verbena venosa I fully agree. It is a most useful and effective bedding plant, and, in my opinion, is the only Verbena worth the trouble of growing for bedding purposes. It endures all sorts of rough weather without being in the least tarnished, and retains its colour to the end of the season when beds of all other Verbenas are blanks. I have often, for I have grown it for more than twenty years, wondered why it is so seldom to be seen. The reason, no doubt, is the supposed difficulty in propagating it in sufficient numbers; and Mr. Robson's statement that not more that one in a thousand will strike, if treated in the same way as other sorts of Verbenas, proves that I am not far wrong in thinking so.

Here we have not the least difficulty in striking it from cuttings, either in the autumn or in spring; but there is another mode of propagating it which I sometimes adopt, and that is by cuttings of the roots. When I take up the old plants I carefully save the long roots—sometimes 2 feet long—which run just under the surface, take cuttings 3 inches long from their points, and insert them round the edge of the pot in the usual way; they are kept in a cold frame all winter, and in February or March placed in the striking pit or frame, where they will soon commence growing, and they make strong plants by turning-out time. The old plants may, instead, remain in the beds until March, and cuttings may be taken off then, and placed in heat at once.

Another method is to cut the roots in pieces with two joints, lay them thickly on the soil in pots, covering them half an inch. They will soon root if placed in heat, and will throw up shoots from every joint.

To obtain a number of plants, principally to take cuttings from in the summer, I always sow a pan or two of seed in spring, and when the seedlings are strong enough I prick them into 2½-inch pots, and keep them under glass till June, when they are shifted into 3-inch pots. By the middle of August they are fine, strong, bushy plants, and from them I take my cuttings, instead of from the beds, which produce cuttings very sparingly. I have at the present time a number of pots of cuttings put in during August and September in a cold close frame; all are struck and growing freely, without, I believe, a single failure.—John Greenshields, *The Gardens, Sarsden.*

TREATMENT OF YOUNG VINES—GOLDEN CHAMPION GRAPE.

I think the complaint of this Vine not doing at present what was expected is owing to what Mr. Thomas Record observes in page 241—it has been exhausted by excessive propagation.

Might I call the attention of the readers of "our Journal" to the treatment I have adopted for all new Vines I purchase from a nursery, and I never yet failed? I turn out the Vine from the pot; if the roots seem in a good condition I repot into pots two sizes larger, using plenty of broken oyster shells and bone dust, with any kind of light sandy garden soil, and grow the Vine in a greenhouse with plenty of air one season. This will restore the lost constitution of the plant, fit the latter to be planted in a vinery, and make a fine Vine, producing better fruit than one planted at once in a vinery as received from a nursery. Should the roots not appear all in good order, carefully take away the soil, and if not full of life wash them, and cut away the bad parts before potting. I should adopt this method rather than inarch a Vine out of health, be the stock what it might.

In striking Vine eyes for my own use I use no heat, but place them in pots in the Vine house; few fail, while if I put in the eyes of any new Vine which I obtain from a nursery there is seldom an eye that grows. Does not this prove the vitality is exhausted—dead to a certain degree? And this is brought about by the constant excitement used by nurserymen to produce plants. Again, eyes can be taken to produce fruitful Vines, and others which are unfruitful from the first—*i. e.*, would not produce fruit soon in a small state.

Some twenty years ago I planted some eyes of the Early White Malvasia, Kienzheim, or Grove End Sweetwater, known in Sussex as Lashmer's Seedling. I give all the names by which I know it. The eyes from a fine robust Vine, taken from spurs that produced fine Grapes, proved very prolific; while those eyes taken from fine strong canes which did not bear, were 30 per cent. inferior in producing Grapes.

Referring to the article I wrote on "Grafting Vines to Promote Hardiness" (page 219), permit me to say some of the Grapes will be sent for inspection to the Fruit Committee of the Royal Horticultural Society, and I trust the readers of "our Journal" will excuse my answering letters by post. My business requires all my time, but, on the other hand, what I have observed during twenty-five years of Vine cultivation shall be communicated in the pages of "our Journal."—R. M. W., *Mount Pisgah, near Sheffield.*

[You are quite right not to answer letters privately. Those who write to our correspondents in defiance of the request to the contrary we publish weekly, must have a very weak notion of propriety, and no thought except for their own convenience.—Eds.]

AUTUMN RAMBLES.

Everybody is on the move in autumn; some for pleasure, some for business, some because they have nothing better to do, and not a few because others, from whom they cannot break away, will go. So I but followed the general fashion when last month I wandered away from my quiet vicarage for a fortnight's run; mine was one of business—real, honest business. But then I have ever a fancy for lightening the work by a little recreation, and while others would be content to rest quietly after the work they had in hand was done, I am for a ramble off

to some garden in the neighbourhood, where I am always sure to hear and learn something which may be of advantage not only to myself, but perhaps, through "the Journal," to others also; and although when I sit down at night I feel perhaps a leetle bit tired, yet I know that it is a fatigue not without service to myself and others. Amongst the places visited during the fortnight was the old city of Norwich, a bustling, thriving place, very different from the dull drowsiness that generally characterises cathedral cities; very different from Canterbury, Ely, Rochester, Winchester, &c., where all the life there is seems so respectable and solemn, that nobody is ever in a bustle, and the very rooks in the close caw as if they thought they ought not to be like their noisy, racketty brethren elsewhere. In Norwich, on the other hand, all is life: "its merchants are princes," its streets are ever busy, and in the neighbourhood you see marks of what all this has achieved in the evidently well-kept seats, whither the more eminent citizens resort after the day's toil is over. Three of these residences I visited, each different in character, but all of them very interesting, as evidencing that wide-spread interest in horticulture that so characterises us as a people, and that, I believe, to an extent not equalled by any other European nation.

My first visit was paid to

J. J. COLMAN, ESQ., CARROW HOUSE,

on the banks of the river Wensum, and in the immediate vicinity of those extensive factories which are known all over the world. The house is situated on the side of the road, and one does not gain at first sight any idea of the beauty of the place or the extent of the grounds; but the moment you enter you perceive at once that you are at the residence of one of those men of wealth who delight in spending, not in hoarding; and in this instance exquisite taste, which is not always the case, has ministered to the expenditure. From the back windows of the sitting-rooms you gain a pretty view of the pleasure grounds and the country beyond, with the river winding pleasantly through it, the house being situated on rising ground. The garden is immediately underneath. The beds are cut out of the grass, and are neither too numerous nor too large, and notwithstanding the trying season they were all in good condition, save the yellow Calceolaria, which here disappoints, as it does in most places, and will have to give way for Golden Feather Pyrethrum, or some other yellow bedding plant. From this the ground again rises, and you catch a sight on the opposite eminence of another smaller arrangement of beds, among which one of Coleus Verschaffelti shone brilliantly. On the left-hand side is a range of vineries with a centre house for plants. In some of these the Grapes had already been cut. Muscats of Alexandria were in full size, though not then coloured sufficiently, and Black Alicante was very good. The borders seemed to have been recently renewed, and round them outside ran a row of Perilla nankinensis.

From this pleasure ground, which comprises about two acres, you pass a little to the left to the kitchen and fruit gardens; though here, as in a good many places, flowers encroach upon kitchen ground, and the *dulce* as well as the *utile* are mingled together. There are glass structures here as well, one of them an orchard house; but when I asked the gardener about it he shook his head, and did not seem to value it very much, although it was capable of being heated. Both fruit and vegetables seemed to be in very good condition, except, of course, the wall fruit, which here, as everywhere this season, was a total failure.

But after all my greatest treat was perhaps the last, for on returning from the kitchen garden my eyes rested in a north border on as fine a collection of Auriculas as I have seen in any private grower's hands for a long time. The plants were good and in fine condition, and all the leading varieties were to be found in goodly numbers. To me they were full of interest. The Auricula was one of my earliest loves (Lothario that I am to speak of one!) and the very coyness she displays, the care she requires, the manner in which she repudiates all neglect, tend to give her a very warm place in one's heart. Chrysanthemums, Roses, Pinks, &c., are here all cultivated; for although Mr. Colman rejoices in his parterres and his houses, he does not, like a good many, snub the florists' flowers. I wish there were many more like him to protect one's favourites. The grounds altogether comprise about four acres, and seldom have I seen gardens better disposed or more abundantly stocked.

When I said Mr. Colman was one of those who spend and do not hoard, I did not mean that he spent all on himself. Witness the schools close by built by the firm, and intended solely for the children of the workpeople. Their numbers may be estimated by the fact that there are from 300 to 350 of their children in the day schools. The education is not gratuitous, but the sum paid weekly is returned to the children in the shape of prizes every half year, the teacher being paid entirely by the firm. It is a noble instance of that large-hearted charity which distinguishes so many of our wealthy merchants. Would that it were universal!

My pen has run on, and I must reserve notices of the other two places for another week, only adding that anyone visiting Norwich would do well to pay this garden a visit, and I am sure he will meet with a courteous reception.—D., *Deal.*

MEMORIAL TO MR. JAMES VEITCH.

HAVING had a visit to-day from a few gardening friends, just as your Journal arrived, we discussed the suggestion of Mr. Thomson, respecting a memorial to the late Mr. James Veitch. Our opinions agreed that something should be done to perpetuate the memory of this lamented horticulturist, and after considering the contents of Mr. Thomson's letter, choice fell upon the latter suggestion of his, and which we are glad to see is so favourably taken up by you. Such a form of showing respect, and doing honour to the memory of this energetic man, would annually stir up the spirit of enthusiasm in all those who are working for the good of horticulture. But why not place a suitable monument over his grave also? The respect of his personal acquaintances would be best shown in that way; but whichever way it is done, I shall be most willing to assist in the good work, if needed.—THOS. RECORD, *Lillesden Gardens, Hawkhurst.*

[If the funds subscribed be sufficient to provide a suitable monument, as well as an annual prize medal, there could be no objection to carrying out both suggestions. This, however, must be left to the decision of the Committee to be formed for realising the suggestion.—EDS.]

SEEDLING ROSES.

THE autumn of 1868 was most propitious for the ripening of Rose hips. I never remember having seen so large a crop on Hybrid Perpetual Roses. All the fine varieties, such as Charles Lefebvre, Duke of Wellington, Lord Clyde, Xavier Olibo, Alfred Colomb, Duc de Rohan, Lord Macaulay, Jules Margottin, Louise Peyronny, Madame Clémence Joigneaux, Madame Alfred de Rougemont, and even that very double Rose Madame Vidot, with a host of others, bore a crop of well-ripened hips.

I am induced to record the effect of that remarkable and almost tropical summer, as it may be many years before its like be again seen, and also to note the most successful mode of treating Rose hips, so that a crop of seedlings may be insured. Last year, in the month of October, about two bushels of hips were gathered here from the most choice sorts of Hybrid Perpetuals; they were at once placed thinly on mats in a vinery, and fully exposed to the sun. This treatment seemed to ripen them thoroughly, for by the end of the year the seeds seemed filled with their white kernels firm as a nut. In January the hips were all crushed with the fingers by boys, the husks partially removed, and the seeds mixed with sand rather moist, and still kept in the vinery. In March they were sown in drills crosswise on a spent hotbed of the previous season, the surface mould, about 6 inches in depth, being formed of light loam and old cocoa-nut fibre. About the end of April the young plants made their appearance so thickly as to look more like a crop of Mustard than Roses. They had no sooner shown themselves than a host of birds, thinking them, I suppose, delicate morsels, attacked them, and would soon have devoured them all. They had a feast of some thousands before their attack on them—only one day—was discovered. The young plants were at once made safe by netting.

About the end of May, the plants, having made their rough leaves, were transplanted into beds raised above the surface with leaves and litter, so as to give a gentle heat; and on these beds a coat of loam and decomposed manure was placed, in which the little fellows were planted, some short grass from the lawn being strewed on the surface to keep it cool. The weather was cloudy, and no shading was required; but few failed, and some hundreds when not more than 4 inches high put forth a blossom, so that one could almost fancy the Rose an annual instead of a long-lived shrub. It was curious to

observe that all these prompt-blooming seedlings produced double flowers of all shades of colour and very interesting. This is, however, reckoned not a good harbinger, as they seldom prove robust-growing, or give in after seasons flowers of a fine character. In the month of July the seedlings were severely attacked with white mildew, which, if it had not been arrested by copious dressings of soot, would have destroyed them all. When transplanted they were computed at twenty thousand, rather more than less. Many of the weak growers have "gone to the wall," but plenty are left.

I have many years since given my method of treating Rose hips, but have thought it would be interesting at the present day to repeat it, as many young Rose-growers may not be aware how easily Roses are raised from seed. Seedling Roses are always full of interest, for although not one in a thousand may be worthy of a name, so numerous and good are our varieties, yet as no two are likely to resemble each other, they keep alive a pleasant hopeful feeling.—T. Rivers.

LATE GRAPES.

Seeing your reply last week (page 311), on late Grapes for a vinery, and among those recommended, Mrs. Pince, I beg to state I purchased a guinea plant when it was first sent out; it is now a good strong Vine. I had twelve bunches on it this season. I have not one perfectly-set bunch in the twelve, not much more than the half of the berries perfect, the other small seedless berries. I do not condemn the Grape, for I hear of some having it good, but if it do the same next year I am resolved to do away with it.

The Editors say they regret they cannot recommend a better light Grape than Trebbiano. I confess we are very short of good late white or golden-coloured sorts forming to Lady Downe's fitting companions. There is Thomson's new White Lady Downe's. I saw good-formed bunches of it at the International Show at Edinburgh, but could not speak of or against its merits; but there is another seedling from Lady Downe's raised by Mr. Melville, at Dalmeny Park, which was exhibited at the Edinburgh Show, and highly thought of by many, but, singular to say, repudiated in the south. It is called Melville's Golden Prince. I have been eye-witness to the growing and habit of this Grape, and believe it will prove the most fitting companion to the Lady Downe's of any Grape yet raised. It will undoubtedly be very much larger in the bunch than Lady Downe's, as it shoulders well, and apparently will hang as well. It has a firm flesh no doubt; but where shall we find a late-hanging Grape without? The Golden Prince is a much finer-flavoured Grape than the Lady Downe's, having a distinct Muscat flavour, the Muscat being one of its parents.—William Bibrell.

THE LARVA OF THE COCKCHAFER, THE "VER BLANC" OF THE FRENCH.

I see in the Journal of last week that your correspondent "Y. B. A. Z." says it is a matter of question whether this pest lives on the roots of grass or on the earth itself. I never heard that it was a question, but I can give pretty positive proof that it is not an earth-feeder. Some years ago, when I was at Versailles with my friend Mr. Standish, we saw whole quarters of Wellingtonias destroyed by this abominable pest. M. Remond, in whose nursery they were, pulled up one or two, and the bark was gnawed off all round. This year I was in the garden of M. Jamin at Bourg-la-Reine. Quantities of his Strawberries were dying, and in clearing away the earth the marauder was found, having cut right through; while, at Fontainebleau, my friend M. Souchet was obliged in his new garden, where he wished to grow Rhododendrons, to dig the soil completely out and make a regular fortification round, so as to keep out the intruders, for they gnawed through the roots, and indeed frequently destroyed good-sized shrubs. Indeed, we might *à priori* argue that it was so, for what else are those strong mandibles for?—not, we may be sure, for eating earth.

The rook is our great friend in destroying these pests. In this neighbourhood they used to be very abundant, the Maple trees being completely stripped by them; but since the great increase of rooks at Eastwell Park and other places in the neighbourhood, they have greatly decreased; so that, notwithstanding that "keeping rooks," as the small boys call their occupation in spring, may be an expense to the farmer, they are his true friends, destroying numbers of these grubs. The larvæ of the Tipulidæ have been very numerous this season, destroying our Lettuces, Cabbages, and Endive. There is no remedy for them but hand-picking, I believe.—D., *Deal.*

GYMNOSTACHYUM PEARCEI AND VERSCHAFFELTI.

Of the many lovely plants introduced of late years, no two are more worthy of notice than these. I have found them invaluable both for the decoration of the stove and the dinner-table.

During the summer I have visited several large gardens, and I was very pleased to hear how highly they were spoken of, and to see such care bestowed on them. The foliage is so exquisitely marked with a thick crimson network, and they can be so easily grown, that when they become known they will be universal favourites.

I grow my plants in large pans with plenty of coarse charcoal for drainage; soil, peat, silver sand, and cocoa-nut fibre refuse, with a little charcoal mixed. In this they succeed admirably, and very quickly make large plants. The flowers, also, are very pretty. A valuable property is, that they succeed well in baskets of my own construction. I suspended one here and there about my stove. A few weeks ago whilst shewing a gentleman round, he said he had never seen Gymnostachynm Verschaffelti grown in baskets before, and that the colour was more distinct than in plants grown in pans. He said every leaf was a complete bonquet.

G. Pearcei is the coarser species, having a tendency to grow more upright than G. Verschaffelti, and the colour of the leaves is very deep. G. Verschaffelti has succeeded the better of the two with me in baskets; the foliage is more closely veined, but both are gems, and attract the eye directly one comes near them. Their appearance is very chaste and beautiful.—F. P. L.

GARDENS IN EAST KENT.—SYNDALL PARK,

The Seat of W. Hall, Esq.

The picturesque county of Kent, with its range of chalk hills, in some parts overlooking the wide-spreading and undulating surface of the fertile weald, and at others rising into precipices, washed by the murmuring surge, offers a rich and varied scenery, of whose beauties the eye never tires. The northern slopes of these hills are in many parts intersected by valleys, which run onwards till they gradually open out into the low-lying marshes that bound the greater part of the north coast of Kent.

One of these valleys or dales forms the western boundary of Syndall Park. From this dale the park rises somewhat abruptly to a considerable elevation, on which are the mansion and principal gardens. It is probably owing to the fact that the most important fronts of the mansion face the south, east, and north, that no part of this sunny western slope is included in the dressed grounds.

The gardens, in which great alterations and improvements have been effected during the last few years, consist of three distinct and separate parts—the glass houses or forcing garden; the pleasure grounds, consisting of lawns, terraces, and flower garden; and the kitchen and fruit gardens. A slight sketch of each department will be offered in the order in which they are named.

The forcing garden may be described as a parallelogram extending from west to east, with the houses facing the south; it is so completely enclosed by a wall as to be quite shut off from the ornamental grounds, to which it is very near. A hip-roofed range 280 feet long by 15 feet wide, is the chief feature here. The formality of its surroundings prevents its being viewed externally from an ornamental point of view, but for general utility and fitness for the purpose to which its several compartments are applied, no exception can be taken to it. It is divided into two parts, of which one is employed for the cultivation of plants, the other for that of fruits. Entering from its western extremity we come first to the Orchid house. The collection of Orchids is being gradually formed, and most of the plants are too young to call for any special mention. All appeared healthy; the fine and abundant pseudo-bulbs of the present year's growth, which were hardly matured at the time of my visit in August, fully attested the vigour of the plants and the care exercised in their treatment. A flourishing Passiflora quadrangularis covered the back wall.

The next house is a stove containing some magnificent plants. Amongst the most conspicuous were a fine Martinezia caryotæfolia, Maranta illustris, Maranta splendida, and a very fine beautifully-coloured specimen of the magnificent Maranta Veitchii. There was also a fine specimen of the striking Caladium Belleymei, and a very fine Phytelephas macrocarpa. Of other specimens claiming a notice, amongst a host of choice plants were Pavetta borbonica; the beautiful Screw Pine, Pandanus elegantissimus; Cyanophyllum magnificum, and Anthurium regale. Nor must I omit to mention some fine plants of the leading kinds of Achimenes in bloom.

The first objects that attracted my attention on entering the next compartment were some good examples of Eucharis amazonica in splendid bloom; the purity of its colour, and delicacy of its perfume, render this beautiful plant a general favourite. The plants were growing in a cool house of large dimensions, being probably as large as the stove and Orchid house combined. Its centre is traversed by a pit or raised bed, in which some large Camellias, a huge Brugmansia, and other plants, were flourishing. The centre of this bed is occupied by a circular basin and fountain. Some plants of the pretty Panicum variegatum were in hanging baskets, suspended from the roof. This beautiful variegated Grass is one of the most useful and ornamental plants in cultivation, its creeping and branching habit of growth, and its peculiar property of emitting roots and branches from every joint, render it useful in many ways, and it may be trained in any form according to fancy. The best method is to fill a pyramidal or globe-shaped wire trellis with moss, and to fasten it to a pot in which two or three plants of Panicum are growing; all that is then required is abundance of water and constant attention to the training, for the more closely the young shoots are tied-in to the moss, the more quickly do they become attached to it by their roots. A fine specimen may also be formed in a few weeks by mixing a few handfuls of light rich soil with the centre mass of moss, and planting a number of young plants in the moss itself. A Tecoma jasminoides trained to the roof was also noticeable for the profusion of its flowers. The back wall was entirely covered with Passifloras and Camellias, with the exception of the space required for a door leading into a fernery.

This fernery is a square building having a span-roof glazed with rough plate glass, and resting on walls of solid masonry. That ample light is thus obtained was fully indicated by the healthy appearance of the Ferns. The house is quite plain, and has side stages, and a square flat central stage, all of slate slabs. The group of Ferns in the centre is tastefully arranged in the form of a raised mound, whose highest part is crowned by a fine Cycas revoluta. Ferns are also planted under the stages amongst fragments of rock; and suspended from the roof are many different kinds in baskets.

Leaving the plant houses, we come next to two vineries, one a Muscat house, and the other containing a number of the leading kinds of Grapes. The whole of the Vines have made fine rods, and will, doubtless, carry some fine fruit next season, which will be their first fruiting year. The next compartment is a fruiting Pine stove, containing a splendid lot of plants, principally Queens. Beyond this is the last house of the range, 80 feet long, filled in the winter months principally with Azaleas. The site of this house was formerly occupied by one of smaller dimensions, in which grew a Black Hamburgh Vine. When the old structure was removed the Vine was allowed to remain, and it now spreads over two-thirds of the trellis of the new house, presenting a singular appearance, for owing to the new house being much wider than its predecessor, the stem of the Vine stands out in the centre of the house away from the sides. The crop was one that would have delighted the heart of an advocate of the extension system, for here were three hundred fine bunches of Grapes on one Vine, thoroughly developed, in the highest state of excellence, and without the slightest flaw in berry, bunch, or colour. I need hardly allude to the healthy appearance of the foliage, as it will be quite apparent to all who understand Grape culture, that a Vine carrying a crop of such high excellence must necessarily have not only healthy foliage, but a vigorous root action. Such a splendid sight as this Vine presented would convert almost any unbeliever in the merits of the extension system, for surely the crop of a single rod, even if its ten or twelve bunches have attained an extraordinary size, can never be of such interest, or make such a demand on the skill of its cultivator, as a Vine similar to that growing here. I noticed, too, a number of strong young Vines in pots, comprising most of the leading varieties. They are an important feature in this establishment, as the earliest Grapes are obtained from pot Vines. The house is connected with a door of the mansion by a glass corridor, by which means the entire range is available to the family in all weathers. The sides of the corridor were principally filled with Orange trees loaded with fruit, and along with them was a fine specimen of Chamærops humilis. The supply of water is abundant, and the arrangements in connection with it are excellent, as each house throughout the range has its separate tap.

After leaving the principal range, an object of interest presented itself in the shape of some model pits of precisely the same shape as the larger houses; in fact, they may best be described as miniature hip-roofed houses having a passage under the hip, with a pit in the front part, having pipes for bottom heat, in which plants can either be plunged in pots or planted-out. There are four of these pits, which are used for producing Melons and Cucumbers on trellises, and the earliest crops of Grapes from pot Vines. The method of supporting the Melon fruit growing on the trellises adopted by Mr. Gifkins, the gardener, is so novel and ingenious, as to be worth describing. A circular piece of sheet tin about 9 inches in diameter is made slightly concave, and its centre is perforated with some small holes to prevent the accumulation of moisture. My meaning will, perhaps, be plainer, if I compare this part of the support to a cream-skimmer minus its handle. Two long flat pieces of tin about an inch wide are soldered to opposite sides of its rim, these flat side pieces or handles having a hole punched at every half inch throughout their length; and two pieces of stout wire having a hook at each end complete this simple but very effective apparatus. When a Melon needs support an end of each wire is hooked through one of the holes in the sides, the support is slung to the trellis wire by the other hooks, and the fruit is placed in the support, which can be raised or lowered at will by means of the holes in the sides.

In a line with the pits just referred to are the succession Pine pits, full of vigorous plants, in various stages of growth. A third range of pits, having the ordinary sliding lights, used in spring for producing forced vegetables and flowers, were filled with well-coloured examples of Golden Coleuses, Achimenes, crimson and yellow Celosias, and various other useful plants, The whole of the glass buildings in this enclosure are efficiently heated by one of Ormson's tubular boilers. Against the wall at the south side of the enclosure opposite the houses, are two useful sheds formed of a wooden framework, covered at top with canvas shading, and open at the front and ends. These sheds were filled with Camellias, Ericas, and a variety of New Holland plants. The collection of Azaleas in pots is healthy and extensive; most of the plants were fine symmetrical pyramids.

In addition to the area occupied by the glass buildings, considerable space is also devoted to beds of those classes of flowers most useful for supplying cut blooms, such as Carnations, Liliums, Gladioluses, and Roses.

A door in the south wall opens into the dressed ground; from this point a wide expanse of lawn dotted with Pinuses, and clumps of huge old Oaks and other deciduous trees, sweeps by the south front of the mansion round to the terrace and flower garden at the east front. The south lawn is belted with groups of shrubs and plantations of Rhododendrons. Under some of the Oaks there were from thirty to forty large Camellias, growing in tubs; they were very noble specimens, all of them being nearly 12 feet high. The dark green hue of the glossy foliage of these huge plants was very beautiful; but when such foliage forms a background for the multitude of blossoms of which they are already giving promise, the effect must be splendid.

The flower garden, occupying the entire length of the terrace, is composed of two sets of beds precisely similar in design, each of which fills nearly half the space of the terrace. Each design may be described as an elongated scroll, forming a number of semicircles, and sweeping boldly and gracefully round at its ends, having a large oval bed in front of its centre, while circular beds of a proportionate size are placed opposite each semicircle. The whole of the beds are laid out on turf; they were well filled with plants, and the effect was gay and pleasing. Water is conducted to the terrace by pipes underground and the beds are quickly watered when necessary by a hose and jet. A small conservatory is attached to the south front of the mansion, and it is there that the large Camellias find a home in the colder months of the year. Two large logs of wood, one on each side of the conservatory, were covered with several varieties of the new Clematises, which were perfect masses of floral beauty, one of the logs over which climbed

Clematis Jackmanni, Prince of Wales, and Rubella, must have had on it fully five hundred expanded blossoms.

The kitchen garden is in a valley in the park at a distance from the dressed grounds; it consists of a walled garden of about 1½ acre; and an adjoining plot, enclosed by a fence, probably covers about 3 acres. In the walled garden were good vegetable crops, some beds of Alpine Strawberries, with abundance of fruit; Cob Nut and Filbert trees laden with nuts, and on the walls plentiful crops of Green Gage and Orleans Plums, and Morello Cherries. A pump stands in the centre of the garden; it is supplied with good water by pipes from a pond at the head of the valley.

On a vacant space of ground between the pond and the walled garden is a Peach or orchard house, 98 feet long by 5 feet wide, heated by pipes. This house is worthy of notice from its being built on a hanging level, so that one end is considerably above the level of the other; another singular feature is the use of slate slabs for the front wall, in place of brickwork.

Near the orchard house is a range of cold pits 50 feet long by 9 feet wide, divided into four compartments; these are devoted in spring exclusively to the production of early Potatoes, which are followed by a crop of Melons, of which large numbers are required, and I have no doubt the supply is quite equal to the demand, for this range contained a crop of at least a hundred fruit, all swelling to a large size, and many of them approaching maturity. Scarlet-fleshed kinds are most sought for, and among the many varieties grown here Scarlet Gem takes a leading position.

Mr. Gifkins evidently has the gardens well in hand, and I heartily wish him success in that most interesting work to a gardener, the gradual development of the gardens under his care, from roughness and sterility to the highest possible state of order and productiveness.—Edward Luckhurst, *Egerton House Gardens, Egerton, Kent.*

IRESINE HERBSTII.

I am pleased to see "D., *Deal*," speak so highly of Iresine Herbstii as a decorative plant. I have grown it two seasons with good effect; it withstood the drought of 1868, and continued to be an object of interest till killed by the frost. With a little attention to pinching and pegging, it can be used for front, second, or third rows in ribbon planting; neither the summer sun nor autumn rains seem to have any deleterious effect upon it. The cold and wet of the early part of this summer made it somewhat late before it could become thoroughly established, but the fine late autumn has amply made up for that deficiency, as the colour and the size of the foliage are now all that can be desired; and I question if we can find anything in habit and colour of foliage to compete with it.

A great recommendation in favour of Iresine Herbstii is the facility with which it can be propagated, as the smallest piece will easily strike, and quickly become a plant, which is a great consideration where only a limited space is allotted for growing bedding plants for planting out.—Rustic.

SOOT AND MILDEW.

Some time in last July a large number of fine Hybrid Perpetual Roses in pots were here (Sawbridgeworth), so infested with mildew as to be white, every leaf being covered with it. Happening to walk out one dewy morning I found them, to my surprise, black. On looking at them more closely I observed the change of colour caused by a coating of soot adhering to every leaf, and on inquiry I learnt that Mr. Perry, our man Friday among the Roses, finding flowers of sulphur quite useless in arresting this Rose pest, had, as a sort of *dernier ressort*, applied soot while the leaves were covered with dew. This was allowed to rest on the leaves for five days, and then, lacking a shower, it was washed off with the syringe placed close to the plants, and used with as much force as possible. The leaves at once assumed that dark green so agreeable to the cultivator, and all the buds opened freely, giving flowers of more than ordinary brilliancy, as if the soot had not only killed the mildew, but had acted as a powerful manurial stimulant, which was undoubtedly the case. Before applying the soot the blossoms should all be cut off, leaving only the buds.

In some cases the mildew was not all destroyed, and so, after eight or ten days, a second dressing of soot was given, which, after a few days, was washed off by a heavy shower, leaving the plants in a beautiful state of health. Since the first operation, as above described, large numbers of Roses in the open quarters were dressed in the month of August with soot. In all cases it has arrested mildew, nearly destroying it. Within these few days (October 6th), the first plants dressed were again attacked with mildew, and are now black with their sooty coat; this will be washed off in a day or two.

A short time since I had some Peas (sown in July), dressed with soot; there was no mildew on them, but I thought it might prove a preventive. The dressing was given when the morning dew was thick on them, but owing to the glossy nature of their leaves it would not rest on them, but all settled on the soil. This might have some effect. At any rate the Peas are bearing a fine crop, and are most luxuriant in their growth. I think it quite probable that soot as a remedy for mildew is very old, but I do not remember having seen it recommended. It may be applied to many things besides Roses; it can do no harm. It must be borne in mind that soot to cure mildew should be dry and fresh.

October 11th.—On having the Roses, which were dressed with soot on the 6th, syringed this morning, so as to wash it thoroughly off, I find every leaf clean, and of a dark green.—Thomas Rivers.

SAXIFRAGA SARMENTOSA CULTURE.

This plant seems to be among the forgotten ones, for I never see its name mentioned, and I wish to recommend it for pot culture. Under proper treatment it produces pyramids of bloom 1½ to 2 feet in height, and more than half as much through; it is then a beautiful plant for conservatory or table decoration, and few plants will bear close inspection better than it, with its prettily-spotted flowers and variegated foliage. Pot the runners at different times in the spring in a compost of equal parts of turfy peat, loam, and leaf mould, with sufficient sand and broken bricks or charcoal to make it light and porous; shift them as required, giving the last shift about August, when they will require 8 or 9-inch pots; and keep them always in a greenhouse or airy pit, except when they are wanted for forcing. They can easily be forced. By forcing some and retarding others, they can be had in bloom all spring and during a good part of the summer. Take off all runners as they appear till the plants show flower; then stop the runners at the pot's edge, and they will make a pretty fringe to cover the pot. They require care in watering at all times. The plant dies after flowering.—J. W., *Oxton, Cheshire.*

NUNEHAM PARK ONION.

As Mr. Cutbush invites reports on the Nuneham Park Onion, I give you my small experience of the matter. On the 26th of February I sowed four rows of White Spanish, four rows of Strasburg, and three rows of Nuneham Park, each row being of precisely the same length—viz., 24 feet, the rows I foot apart, and side by side with each other. The following is the result:—Four rows White Spanish weighed 19 lbs.; four rows of Strasburg, 33 lbs.; three rows of Nuneham Park, 33 lbs., the same weight precisely of the four rows of Strasburg. The Nuneham Park Onions are rather flattish, something of the Tripoli shape, pale-skinned, and mild in flavour. I know nothing yet of their keeping properties, as I never grew them before, having been induced to do so this year from the remarks and advertisements I read in this Journal. I intend trying their keeping qualities with the Strasburg, and if they stand the test I shall grow no others in future, unless, indeed, some others turn up to beat them again. I may add there was not a thick-necked Onion in the lot.—Joseph Metcalf, *Templeogue, Co. Dublin.*

WATER RENDERED CHALYBEATE.

From the well here we used to draw the water by means of a windlass and bucket, with much inconvenience, consequently I substituted a pump and iron piping. Now, this has rendered the water very unpalatable, and although it is still clear, it oxidises the sides of a water bottle if allowed to remain overnight, yet it will be perfectly clear upon pouring out. Again, even upon pumping all the water out of the suction-pipe, so as to procure some direct from the well, it is strongly and unpleasantly chalybeate. Would you have the kindness to tell me the best means of remedying it at the least expense?—J. M., *Worth, Sussex.*

[The pipes should have been vitrified, or lead pipes used,

and the water that stood in them pumped off previously to drawing from the level. We should be glad if some of our readers would state their opinions, as the matter is of general importance.]

ROYAL HORTICULTURAL SOCIETY.

October 19th.

Fruit Committee.—At the meeting held this day, George F. Bleukins, Esq., was in the chair. The Rev. George Kemp having offered two prizes of £3 and £2 for the best six bunches of Grapes, grown in the open air without any protection whatever, a very spirited competition took place. There were eight exhibitions of Royal Muscadine, and only one of any other variety—viz., the Black Prince, which was quite unripe. The Royal Muscadines were in almost every instance good, both in appearance and flavour; the first-prize lot of Royal Muscadine, which came from Mr. Miller, gardener to J. F. Friend, Esq., Northdown, Margate, especially so, and finer than some of the same variety exhibited from the neighbourhood of Paris, thus proving that our own climate is capable of producing nearly as good Grapes as many parts of France. The second prize was awarded to Mr. Tranter, Upper Assendon, Henley-on-Thames, also for Royal Muscadine. Mr. Foster, Leigh, Essex; Mr. Earley, Digswell; Mr. Garland, Killerton, Exeter; Mr. Hepper, The Elms, Acton; Mr. Lynn, Hedsor; and Mr. Smith, Turnham Green, likewise competed. It was announced that the Rev. G. Kemp would offer similar prizes for out-door Grapes at the last October meeting next year.

W. Looke, Esq., Clove House, Seend, Melksham, Wilts, sent specimens of a very curious and interesting sport from the Citronelle Grape. This resembled in its peculiarity of colouring the old Aleppo, or Variegated Chasselas, some of the bunches being produced black, some green, others with one half or a few berries green and the rest black, some striped, or one half of the berry green and the other black, altogether presenting a singular appearance. The flavour of these berries did not differ from the Citronelle, which is a small white Chasselas with a pleasant Sweetwater flavour. Mr. Eckford, gardener, Coleshill, sent specimens of his seedling Grape, called Coleshill White Hamburgh. In appearance it somewhat resembles Buckland Sweetwater, with the texture of the Tokay, having no point of resemblance to the Hamburgh class of Grapes. The Committee did not consider it worthy of introduction.

Mr. Woodward, gardener to Mrs. Torr, Garbrand Hall, Ewell, sent a very splendid dish of Sir Charles Napier and another of British Queen Strawberry, ripened in the open ground on plants forced early in spring, and afterwards planted out. These would have been creditable enough in June. A special certificate was awarded. Mr. Richards, gardener, Stoke Park, Slough, sent three magnificent fruits of Smooth Cayenne Pines, weighing upwards of 24 lbs. These were well grown, and noble examples of cultivation. A special certificate was awarded. Mr. Hepper, gardener to J. B. Walmsley, Esq., The Elms, Acton, sent a dish of Plums, produced on the wood of the current year's growth, a sort of second crop. Mr. W. Paul sent specimens of Pond's Seedling Plum, produced in the same way. Messrs. Harrison & Sons, nurserymen, Leicester, sent a branch clustered with fruit of Harrison's Late Cluster Plum, which in appearance resembled the old Muscle Plum. It proved of very bad quality, although it may be useful as a very late tart Plum. Henry Webb, Esq., sent some fine fruit of Urbaniste and Beurré Diel Pears. Mr. W. Paul sent fruit of a Pear received from America as Tyson, which very much resembled the Seckle, although much larger and coarser. Mr. Chaff, gardener to A. Smee, Esq., Wallington, sent some noble specimen fruits of Lord Derby Apple, a good, useful, early kitchen sort. Mr. Denning, gardener to Lord Londesborough, Grimston Park, sent some fruit of an Apple known locally as the "Elmender." It was not possessed of much merit.

Mr. Miller, gardener to J. F. Friend, Esq., Margate, sent a fruit of a hardy ridge Melon, which proved of very fair quality. Mr. Lee, The Gardens, Blenheim Palace, Woodstock, sent fruit of a very pretty red-fleshed Melon, which was possessed of no particular merit. Mr. Carr, gardener to P. L. Hinds, Esq., Byfleet, Surrey, sent a fruit of the Avocado Pear, a tropical fruit. It is of the size of a small Melon, oval in shape; the skin deep green, coloured a little on one side, and spotted with dull red all over. The flesh, which is about an inch in thickness, is of a soft pasty character, of a pale yellow colour, covering one large seed in a kernel, like a Plum. As a dessert fruit it is uneatable. As this is the first time this fruit has been ripened in this country, Mr. Carr was specially commended for its production.

M. Le Conteur, Belle Vue, Jersey, President of the Royal Jersey Horticultural Society, sent some uncommonly large Onions, which had obtained the first prize at the Society's Show held in Jersey. They were considered to be the Globe Tripoli. It was ordered that one of them be cooked, and again submitted at the next meeting. They were highly commended by the Committee. Messrs. Ratley & Silverlock, seedsmen, 412, Strand, sent examples of the new Onion called Bedfordshire Champion, which bears a close resemblance to the old Globe. Mr. Hepper, Acton, sent a brace of Cucumbers, the produce of a cross between Masters's Prolific and Manchester Prize. Mr. Hepper also exhibited a small dish of Dillistone's Early Pea.

Messrs. Veitch & Sons, Chelsea, exhibited a great variety of Beets, examples of which were cooked for the opinion of the Committee. These included Notting's Dark Red, Pine Apple, Dell's Crimson, Cattell's Crimson, Osborn's Red, Dark Red Egyptian, Veitch's No. 2 and No. 3. The finest-flavoured and best variety proved to be Veitch's No. 2, which was awarded a first-class certificate. Messrs. Veitch also exhibited samples of Scarlet Brazilian, Beck's Improved Seakale, and Spinach Beet, the leaves and stems of which variety only are used.

Mr. Wm. Paul, nurseryman, Waltham Cross, sent a collection of twenty-five varieties of Potatoes, many of them very fine in appearance; a special certificate was awarded. Messrs. Sutton & Sons, Reading, also sent a collection of fifty-three varieties of Potatoes, comprising most of the leading sorts, and some extremely handsome. It is impossible, however, to judge of Potatoes by their appearance alone. A special certificate was awarded.

Floral Committee.—The number of plants sent on this occasion was unusually small, no doubt owing to the inclemency of the weather.

Mr. B. S. Williams sent a fine group of Orchids, to which a special certificate was awarded. The most noticeable was a species of Aerides, in the way of A. suavissimum, but with more colour in the sepals. A plant of the latter was sent for comparison, but it was thought not sufficiently expanded in flower to judge of the difference between it and the new sort. In this group was also a fine plant of Angræcum eburneum, with a long spike of flowers; Odontoglossum bictonense, with two handsome spikes; Lælia Perrinii, Calanthe vestita rubra, Miltonia Morelliana, Lycaste Schilleriana, the curious Oncidium ornithorhynchum, Pleione lagenaria, Zygopetalum crinitum and Z. Mackayi, Barkeria Skinneri, with four spikes; Vanda tricolor insignis, and some good forms of Lycaste Skinneri.

From Mr. Denning, gardener to Lord Londesborough, Grimston Park, Tadcaster, came three finely-flowered plants of Vanda cærulea, the largest specimen being a very fine example of successful cultivation, the plant being feathered with foliage to its base, and having three spikes of flowers, containing forty-eight expanded flowers, which were finely coloured, and one bud. The Floral Committee recommended to the Council that the Lindley medal should be awarded to this fine example. One other specimen had twenty three expanded flowers, and one eight expanded flowers. With them came a well-flowered plant of Cattleya exoniensis, and to this and the Vandas a special certificate was awarded.

From Mr. Wilson, gardener to William Marshall, Esq., Clay Hill, Enfield, came Odontoglossum Rossii var. Warneri, a large-flowering form of this handsome species, having pale sepals with large dark spots, pure white petals, with a yellow crest, and pale rosy purple colouring, which was awarded a first-class certificate; and a cut specimen of Lælia elegans Wilsoni, which was thought to be inferior to others in cultivation. In regard to O. Rossii var. Warneri, it was thought by some to be possibly identical with Odontoglossum Warnerianum.

From the Royal Horticultural Society's gardens came some well-flowered plants of Odontoglossum grande and Lælia Perrinii, and a pan of Pleione Wallichiana beautifully flowered, to which a special certificate was awarded.

Mr. Thomas Moore, of the Botanic Gardens, Chelsea, received a first-class certificate for Athyrium Filix-fœmina Elizabethæ, a very handsome seedling form of the Lady Fern, brought for the purpose of showing how varied are the forms which will come from seed.

From Mr. Eckford, The Gardens, Coleshill, came zonal Pelargonium Purity, in the way of Madame Werla, and having a pure white flower of fine form, with a carmine ring round the eye. It was regarded as a very good variety, but thought to be not distinct from other kinds in cultivation.

Messrs. Standish & Co. sent a plant of their Ascot Yellow Perpetual Picotee, to show the excellence of its habit and freedom of bloom.

From Mr. H. J. Barlow, Vine Cottage, Plymouth, came blooms of a seedling double Fuchsia, with scarlet tube and sepals, and a blotched crimson and rose corolla with curious serrated edges.

Mr. J. E. Dwelly, Marlborough, sent blooms of a white Hollyhock, but in very poor condition as shown.

General Meeting.—J. Bateman, Esq., F.R.S., in the chair. After the election of one new Fellow, the Chairman pointed out the leading plants exhibited, remarking of the Pleiones that in time of flowering and appearance they are the autumnal Crocuses of the Himalayas. They require heat with plenty of moisture while making their leaves, and then to have a dry season and a cooler house for flowering. Dr. Hooker had mentioned in his "Himalayan Journal," several other species besides the five known to us. Of Vanda cærulea from Lord Londesborough's gardener, Mr. Bateman said he did not remember the plant having been ever exhibited in such beauty before, and fine as the specimens were which Messrs. Veitch had shown, they were not as the specimens exhibited on the present occasion. The cultivation of this Vanda, like that of the Pleiones, was not understood, for the majority of Orchid-growers failed with it, and had a doleful tale to tell after three years. At Lord Londesborough's it was grown in a corner of a house facing the north-east, where there was little sun but plenty of light. Dr. Hooker in his "Himalayan Journal," had given an account of finding it in great beauty and profusion in Oak woods near an Indian Stonehenge. Mr. Bateman then read an extract from Dr. Hooker's work describing the position it was found in, and the size of

the panicles of flowers. After brief allusion to Cattleya exoniensis as being unequalled in the delicacy of its flowers, Mr. Bateman drew attention to a beautiful specimen of Barkeria Skinneri, from Mr. Williams, and stated that the great secret of success in the cultivation of this plant, is to grow it on pieces of board so as to expose its roots to the air, not in earth, which is an abomination to it. A new Cypripedium, from Costa Rica, was then noticed as being of good habit and producing as many as forty or fifty flowers on a stem, but unfortunately not at one time, for before a second flower comes out the first is on the point of departure. The Avocado Pear, Messrs. Sutton's Potatoes, and the Currant Tomatoes shown at the previous meeting, were then briefly referred to, Mr. Bateman remarking of the last that they were most excellent.

Mr. Blenkins drew attention to a seedling Walnut, from Mr. Cox, which had been exhibited last year, but which had on this occasion arrived too late to be submitted to the Committee. The nuts were more elongated than the common, the shell very thin, and the flavour good.

The next meeting will be held November 16th, on which occasion prizes are offered by W. Wilson Saunders, Esq., for collections of winter bedding plants in pots or boxes, and by the Society for large-flowering and Pompon Chrysanthemums, for cut blooms of Chrysanthemums, and for plants in pots bearing decorative fruits.

WAYSIDE JOTTINGS.—No. 2.

Shortly after my visit to the locality described in my last budget of notes (see page 138), I was induced to examine another piece of bog land nearly a couple of miles from the shore of the Solway Frith, about a dozen acres in extent, and known as Hanging-Show Moss, situated towards the western extremity of the extensive parish of Holme Cultram.

On approaching the Moss I was much struck with the geological features of the surrounding district. All round were to be seen sandy eminences or hummocks, in shape not unlike the segment of a sphere; between their bases lay strips of bog land, apparently landlocked among these hills in such a manner as to render the drainage of them a matter of difficulty as well as of expense. The contrast between the botanical productions of the hills and of the intervening bogs was very marked.

In the narrow sandy lanes were large quantities of the wild Pansy, the flowers being of all shades of colour from deep violet to almost pure white, and intermingled along the hedge-banks in the most pleasing manner. The hedges themselves were gorgeously bedecked with the bright yellow blossoms of Furze and Broom, striving as if for the mastery, and entirely throwing into the shade the straggling patches of Hawthorn, of which the original fence had no doubt mainly consisted. I do not recollect ever before having seen the Gorse in such profusion of blossom, and I fully sympathised with the feelings of Linnæus on seeing this common English shrub in bloom for the first time. Among other plants conspicuous in the hedgerows was the common Burnet Rose (Rosa spinosissima); while deeply rooted among the loose sand of the hedgebanks were some fine specimens of the Storksbill (Erodium cicutarium). In one place not far from the hamlet of New Cooper, I found specimens of a small cruciferous plant, not at all common in the neighbourhood—the Teesdalia nudicaulis; and at the next turn of the lane I discovered another plant, to which I was almost equally a stranger—Thymus Acinos, or Basil Thyme. Of this last I could only find a single patch of not more than half a dozen plants.

On arriving at the Moss, I found some labourers at work digging peats for winter fuel. Observing that I was busy collecting herbs, one of the men came gravely up to me, and begged that I would prescribe for him, as he declared himself quite a martyr to rheumatism. I had great difficulty in persuading the simple-minded turfcutter that I was not a compounder of potions of the Dr. Coffin type, but merely an inquirer into the works of Nature as presented in the Moss from which he was cutting peats. In an abandoned peat-pot hard by I pointed out to him where the pretty little Marsh Violet (Viola palustris), was in blossom, and asked him to compare it with the common Dog Violet, growing on the bank by his cottage door, with which he persisted that it must be identical.

Leaving him to resume his work, I strolled across the bog, which was very plentifully sprinkled over with the shining leaves of White Rot (Hydrocotyle vulgaris), Cotton Grass (Eriophorum), of at least two varieties, and Marsh Cinquefoil (Comarum palustre). The pretty but diminutive blossoms of the Cranberry (Vaccinium Oxycoccus), were tolerably plentiful in one part, while the star-like tufts formed by the fringed leaves of the Sondew (Drosera rotundifolia), not yet in flower, were to be seen in another. At the lower end of the Moss, again, like a clump of low Willows, was a considerable bed of Myrica Gale, or the Bog Myrtle, the leaves of which emit a strong and not unpleasant odour when crushed in the hand. The Little Bog Stitchwort (Stellaria uliginosa), grew in some of the more spongy parts of the bog, the examination of which yielded me a degree of pleasure which amply compensated me for the exertion of walking some four or five miles to pay it a visit.—H.

DELAWARE PEACHES.

Among the first Peach orchards planted in this State were those of Mr. Ridgway, near Delaware City, in 1833; Major Reybold's, in 1838; and Mr. Spearman, in Newcastle County, in 1838.

Mr. Todd, of Dover, planted the first orchard in that vicinity, in 1840. During that season one orchard of about forty acres realised a profit of about 9000 dollars, and this fact started the great Peach excitement, which still exists, and so far has resulted in the planting of about two million trees in Delaware and on the eastern shore of Maryland. They consist of the following varieties:—Hale's Early, Troth's Early, Early York, Crawford's Early, Reeve's Favourite, Old Mixon, Ward's Late, Fox's Seedling, Crawford Late, Delaware White, Patterson's and Freeman's White, and Smock Yellow. The Peaches ripen on these trees in the order given above, and therefore a good supply is kept up from about the 20th or 26th of July until nearly the close of September. After planting the trees, the ground is cultivated in corn for three years, but after that the trees shade the earth to such an extent that it will not pay to plant any kind of crop. The ground, however, has to be well cultivated every year, and manured, if the trees are expected to bear well and live any length of time. It has often been stated that the trees will not bear to any extent more than four or six years; but the most intelligent and experienced gentlemen in the business say that the trees will remain profitable for fifteen or twenty years, and that the orchards which die out in six years do so because they have not received proper care and culture.

Land is now selling in Caroline County at from 10 to 25 dollars per acre.

The orchards in Delaware occupy from 40 to 1000 acres each, and when the trees are from six to eight years old, from 3 to 4 bushels of Peaches will be gathered in a season from each tree, but the general average is about 2 bushels which in a season like the present will realise from three to three and a half millions of dollars. On 150 trees of Early Troth, planted near Middletown, 700 baskets were realised this season. The shipments from this station amount now to 5000 baskets per day. About 120 of the orchards in Delaware were sold at an early date to speculators, at from 40 to 50 cents per basket, in Kent County, and 50 cents Newcastle County, the owner of the orchard having the Peaches picked and delivered at the nearest station.

So far as the early Peaches are concerned, the parties who sold their orchards have had the best of it, as those who shipped their Peaches to a market have not realised much profit, and in some cases they suffered a loss. The Peaches were small, in consequence of the great number on the trees and the dry weather, and thus they were sold at a lower rate than usual. The Peaches to be shipped after these, and from then until the close of the season, will be large and fine, and then the grower expects to realise his profit. Mr. S. Townsend, below Middletown, has 40,000 trees of the different varieties, and all of them are as full of Peaches as the limbs of the trees will bear.

It is estimated that at least 3000 men, women, and children are now engaged in Delaware in gathering the crop. Men are paid 1 dollar per day and boarded, or 1½ dollar if they board themselves. Women and children receive about half of the above rates. Employment is also given to a large number of persons in various parts of the country in the making of baskets and crates, the former costing from 20 to 35 cents each, and the latter 20 cents each.

The Peaches reach Philadelphia and New York in better order than in former years, in consequence of the recent improvements made in ventilation, particularly in the cars belonging to the Philadelphia, Wilmington, and Baltimore Railroad.

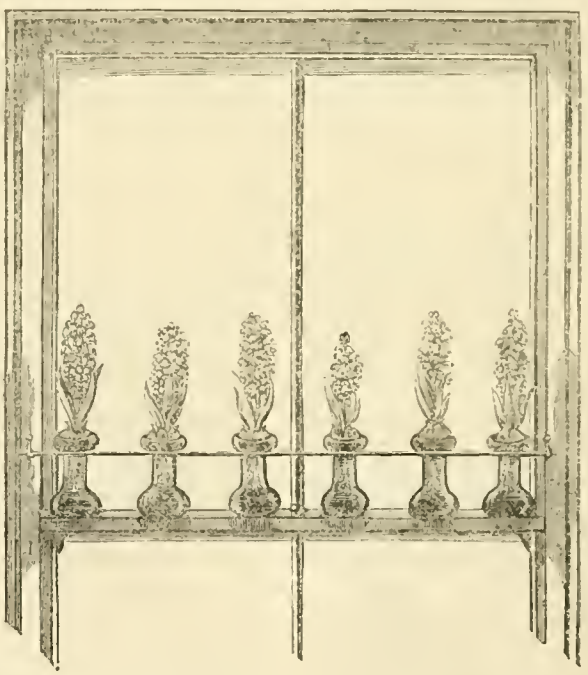
To give the reader some idea of this great business, we procured the following statement of the number of car loads sent

over the Delaware Railroad to New York, on one day; Laurel, 1 car load; Seaford, 2; Bridgeville, 4; Greenwood, 2; Georgetown, 2; Milford, 6; Harrington, 6; Canterbury, 2; Camden, 10; Mooreton, 3; Dover, 8; Brenford, 3; Clayton, and stations on the Delaware and Maryland Road, 20; Sassafras, 4; Blackbird, 1; Townsend, and from stations on the Kent and Queen Anne's Road, 11; Ginnues, 2; Middletown, 10; Armstrong, 5; Mount Pleasant, 3, and Willow Grove, 1; making a total of 103 cars, each carrying 16,000 lbs, each basket weighing about 32 lbs.

Since the commencement of the present Peach season, about 700 cars have passed over the road, conveying to market over 11,000,000 pounds of Peaches. Each car carries 500 baskets, each basket holding about five-eighths of a bushel. In addition to the Peaches sent from this State by rail, thousands of baskets are sent to Philadelphia and other places by steamers passing through the canal, which passes near to some of the orchards, and by vessels plying in the rivers and creeks throughout the State. The whole yield this season throughout the Peach-growing region is estimated at 5,000,000 baskets. Notwithstanding this immense amount, it is said that a large number of acres of ground now devoted to agricultural purposes, will be planted in Peach trees next fall, as it is thought new markets will be opened at more distant points, as railroad facilities offer, and improved methods of keeping Peaches are introduced.—(*Philadelphia Ledger*).

SOMETHING ABOUT HYACINTHS.

In one of Thomas Hogg's gossiping books about florists' flowers, published about 1822, he devotes a chapter to the Hyacinth, and at the close of it gives a list of 155 sorts as representing the best flowers in cultivatien, and of those 155 flowers 124 were double, and only 31 single. At that time the popular taste ran after double flowers, and it is only within the last fifteen or twenty years that the single flowers, with their much denser and larger spikes, have come to be better regarded than the less symmetrical spikes of the double kinds. In the list of the double kinds I find many that are to be met with still in some of the old-fashioned bulb lists of the present day, but of the thirty-one single kinds only very few. Within the last ten years there has been a perceptible difference in the number of double flowers imported into England, as they have fallen off considerably; while the increase in the demand for single kinds has multiplied to a large extent. If anyone needs a proof of this, let him look over a stand of twenty-four or eighteen Hyacinths staged by Mr. W. Paul, or Messrs. Cutbush & Sons, and not more than three or four double varieties will be found among them. The single varieties, as a rule, have the largest, the fullest, and the showiest spikes of blossoms, while they are generally more decided in point of colour, having more attractive and definite hues. It is for these reasons the single kinds are preferred to the double.



Just now—

> "When sad autumn comes
> stealthily creeping,
> With its ruin of russet and
> grey"—

is a fitting time to present a few words respecting the cultivation of the Hyacinth in glasses, &c. Well and truthfully has it been said, that "of all the delightful recreations that can dispense their kindly charm through the domestic circle, there is scarcely one so pregnant with the highest and purest enjoyment as the cultivation of a few Hyacinths in water. From the commencement of the pleasant process till the last flower decays, it is an almost daily recurrence of joyous surprises—the ceaseless unfolding of new beauties." I cultivate a number in glasses yearly, and from the time that the autumn'e

> "Red leaves fall in sorrow around us,"

the sure precursor of winter's approach, and through the period of its sometimes blustering and fierce, and yet necessary reign, up to the time that young spring comes forth to

> 'Write love's fair alphabet upon the sod
> In many-coloured flowers,"

each day may be said to bring its special interest; for in their continuous development there is so much of fresh revelations of undreamed-of charms, that the task of tending them, to one touched by a genuine and genial love for flowers, never falls to the low level of irksomeness.

I annually grow about eighteen Hyacinths in glasses, and invariably place them all in water at the same time. I have tried different times in the hope of insuring a succession of bloom, but it has happened that those placed latest in the glass were among the first to bloom. I have also ceased to put the bulbs in the water so early as I used, and now do not think of putting them in till the middle or end of October. Fresh rain water is to be preferred, and the glass should be so filled that the water only just touches the base of the bulb. Rain water should not be employed unless it is quite fresh, or otherwise it soon becomes putrid, and causes the roots of the bulbs to decay. If there is no alternative but to employ hard water, it can be exposed to the action of the sun or external air for a time, so much the better. My experience has taught me that hard water used directly it is taken from a well is apt to cause the roots to become a mass of pulp, highly offensive, and fatal in its effects. Two or three lumps of charcoal placed in the glasses about two or three days before they are occupied by the bulbs, in order to allow of the charcoal becoming saturated and sinking to the bottom, will keep the water from turning rank, and prevent the necessity for its being often changed. Some of my best flowers have been in glasses, the water of which was not once changed. Place the glasses in a dark and rather cool situation until the roots have nearly reached the bottoms of the glasses, when they can be brought to the light. A month or six weeks' imprisonment will bring the roots to this stage of development. The most airy and lightest part of a sitting-room, but as far from the fire as possible, is the best position for them. When the bulbs have been in the water about a week or ten days, the base of each should be examined, and any decaying or slimy substance removed. As the shoot of growth increases in size, evaporation will take place, therefore the water should be replenished at intervals, care being taken that what is supplied is not lower in temperature than that in the glass. The foliage of the plants should be kept scrupulously free from any dust or dirt; a small piece of sponge will remove this with but very slight trouble. When the flower spikes begin to show themselves the glasses should be kept filled to the rim with water, as at the point of flowering the bulbs absorb a great quantity of moisture.

I need scarcely mention, that as the Hyacinths grow they must have all the light and air possible, to prevent them

from "drawing." I find nothing better than a window ledge or a table near it, and if a bay window so much the better. My own glasses I place on the window ledge, and halfway up the window, at the junction of the sashes where the fastening is placed; here they do admirably, only when the sun becomes warm they should be shaded from its action, or removed in the middle of the day. Where there is not width of bar enough to support the glasses at the junction of the sashes, as in the case of my own window, then a brass rod can be used, to pass along by the neck of the glass, and drop into a rest on either side. I append a rough sketch of my own contrivance, in the hope of making it clear to your readers.

This arrangement certainly prevents the bottom sash from being raised, but it does not in the least interfere with the top sash coming down. At this stage the great points in the cultivation of the Hyacinths are—a plentiful supply of water, protection from hot sunshine, and the continual raising of the support as the spike of flowers increases in length.

Beyond giving a list of varieties I have found to be specially adapted for cultivation in glasses, I have done with the cultivating process. Alas! how poorly such a system of cultivating the Hyacinth appears to be understood! Let anyone take a walk about the suburbs of London during the spring months, and observe the poor, neglected, starving specimens of the Hyacinth that meet the eye at almost every stage of the progress, and he will readily understand how much a better knowledge is required. If these remarks can aid the dissemination of this knowledge, and can be made the means of inciting some to pursue this pleasant pastime, this paper will not have been written in vain. The following varieties are fine, varied, and moderate in price:—

DOUBLE HYACINTHS.

Lord Wellington, waxy blush, very fine.
Bloksberg, pale lilac, striped with blue.
La Tour d'Auvergne, pure white.

SINGLE HYACINTHS.

RED.

Duchess of Richmond, bright pink.
Emmeline, delicate blush, striped with pink.
Gigantea, pale flesh.
La Dame du Lac, blush, suffused with pink.
Madame Hodgson, light pink.
Norma, waxy flesh colour.
Robert Steiger, fine deep crimson.
Sultan's Favourite, flesh, striped with pink.

BLUE.

Baron Van Tuyll, deep glossy violet.
Bleu Mourant, dark blue.
Charles Dickens, dark porcelain blue.
Emicus, dark blue, light centre.
Grand Lilas, delicate azure blue.
Leonidas, clear bright blue.
Mimosa, dark blue purple.
Orondates, pale porcelain blue.
Prince Oscar, striped deep blue.
Regulus, shaded lavender blue.

WHITE.

Alba Superbissima, pure white.
Anna Paulowna, blush white.
Cleopatra, creamy white.
Grandeur à Merveille, waxy French white.
Grand Vainqueur, pure white.
Madame Van der Hoop, pure white, extra fine.
Mont Blanc, pure white, very fine.
Seraphine, creamy blush.
Themistocles, pure white.
Voltaire, blush white.

YELLOW.

Anna Carolina, clear yellow.
King of Holland, pale yellow, shaded with reddish orange.
Heroine, pale yellow.

—Via.

POMOLOGICAL GLEANINGS.

We have seen some specimens of the Dalrymple Damson mentioned in the following extract of a letter. The Damsons on the branch mentioned were like a cluster of Grapes. It is much larger, but less flavoured than the common Damson, and is evidently very hardy.

"The fruit off the branch is grown in the full sunshine. The small branch is from a tree which loses the sun at 10.30 A.M., and the other branch is from a tree planted on the edge of a wood, and under a Beech tree, and, therefore, never sees the sun, excepting very early in the morning at midsummer. Whatever this Damson may turn out with you, it is a most valuable variety here (St. Boswell's, N.B.). It is very dwarf in habit, an enormous bearer, my trees giving from 1 to 1½ bushel each. It is late in ripening."

WORK FOR THE WEEK.

KITCHEN GARDEN.

Give air freely to *Cauliflower* and *Lettuce* plants under glass; indeed, the sashes should merely be used to throw off rain, for the plants will do all the better if kept hardy. Take advantage of the first sunny day, when the ground is in a dry state, to earth-up *Celery*. The *Mushroom* beds made in September will now be bearing; it is a good plan to sprinkle or syringe the surface of the bed a week or so before the Mushrooms make their appearance, more especially in Mushroom houses where a fire may have been used occasionally. This is far better than watering after the Mushrooms have come through. The water, however, must not be allowed to penetrate the manure, but merely to soften the soil. A sowing of *Peas* on a well-sheltered dry border may soon be made, and do not spare the seed, for it will be some time exposed to the depredations of mice.

FRUIT GARDEN.

The present time is the most favourable for lifting and root pruning such fruit trees as are growing too luxuriantly to produce fruit; and as the autumn is the season generally fixed upon for making new borders or renovating old ones, it is well to remind those about to plant fruit trees of the danger everywhere apparent of making borders too deep as well as too rich. When we see in practice how small a space of border is requisite to support fruit trees in health and productiveness for a number of years, we might be anxious to know how it happens that such unnecessary expense is incurred to do a positive evil, if we were not aware that in many instances it arises from a desire to do the work overwell, and with a misconception of what is necessary to maintain that moderate amount of growth by which alone we may expect permanent results. The border should not be deep—a depth of 18 inches is ample. The soil should be maiden loam of a moderate consistency; no dung whatever should be used, and the roots should be prevented from passing below the border by a considerable depth of rubble or rough paving stones placed so as to leave cavities between them. This border should dip from the wall, so as to throw off surface rains and be well exposed to the sun; and further, I would only make the border 4 feet in width at first, and afterwards extend it as required.

FLOWER GARDEN.

The weather is still favourable for executing alterations, and when these are in hand they should be prosecuted with the greatest possible dispatch. Planting, or the removal of large evergreens, cannot be finished too soon, for it is of the utmost importance that the plants should be afforded some chance of making fresh roots before the trying winds of March set in. See to even small plants being secured against wind, for these are often much injured by being blown about after planting. A small stake and a few minutes' work would prevent this. As soon as the leaves have fallen secure a stock of Briars for budding upon. Let the roots be well trimmed, cutting back closely the strong ones, for these, if left, will be of little use except to furnish an endless supply of suckers. Choice plants in the parterre can no longer be depended on for display; it is therefore desirable at this period to look over the masses and beds, and see if there be any choice plant of a tender character which it is desirable to secure for next year. Such may be potted with a ball and wintered in a cold pit. As the winter approaches, protection of some kind should be provided for tender plants and shrubs; almost any material is eligible if it will in a considerable degree throw off wet. Canopies for this purpose should be so contrived as to admit of one or two sides being opened at pleasure. If only one, it should be placed on the north or west side—certainly not on the south, as the excitement occasioned by fits of sunshine is apt to prove very prejudicial. The covering or canopy should by no means be allowed to touch the plant, and the greater the space allowed between it and the plant the better it will afford protection. It is bad practice to bundle the shoots together like a broom in order to make them occupy a more limited space. More injury is occasioned by confined dung in a majority of cases than by lowness of temperature. Hoodings of straw so formed as to overlap the protecting material beneath are very good and simple protectors, and if rightly contrived may be removed with as much facility for ventilation as the top of an ordinary hand-glass. Oilcloth will also make a good protection when formed into a kind of cone, on the sides of which a small flap or two may be made to open without admitting rain. Before the application of any top covering I would advise that an inch or two of the surface soil around the collar should be removed and replaced with dry cinder siftings, the newer the better, or, where it can be had, cocoa-nut refuse. The latter should be piled as high up the stem as the plant will admit, taking care not to choke too many of the lower leaves; and if the canopy is so contrived as to overlap this mound the covering will be

complete. The only care that remains is to give air in favourable opportunities, particularly avoiding cutting winds, which in all probability do more harm than frosts. The planting of bulbs must now occupy attention. For those of Gladiolus choose a warm thoroughly drained situation; work the soil well by deep digging, and add plenty of rotted manure. Elevate the bed or patch a few inches above the ground level; plant the bulbs 5 or 6 inches deep and 6 inches apart, surrounding them with 1 inch of sand before covering with soil; protect during the winter against excessive wet and frost with a thick layer of sawdust, old tan, dry litter, an old carpet, thatched frames, or tarpaulin. The last three coverings must be removed during favourable weather, and the former coverings should be entirely cleared off when the plants appear. In small gardens, where the ground is required for spring-flowering bulbs, plant two or three in a 6 or 8-inch pot. As soon as the beauty of the spring flowers is over prepare for the reception of the Gladiolus bulbs; in planting out great care must be exercised in removing them from the pots, so as not to disturb the roots. In wet, cold soils the bulbs would be safer if stored in pots during the winter and planted out in May. When the blooming is over the bulbs may either be lifted in patches, potted, and treated during the winter as already recommended, or allowed to remain in the ground, and protected as described above. Established patches produce a finer display than the bulbs would if annually disturbed and broken up.

GREENHOUSE AND CONSERVATORY.

Plants past their best should be replaced at once by something of a more showy character. When the principal collection of Chrysanthemums comes into bloom a selection should be made of the best and most useful sorts, for there are many worthless varieties in cultivation, and it is better to grow duplicates of really good kinds than to retain such as are but indifferent merely for the sake of having a long list of names. Give timely attention to providing a succession of bloom with which to keep the conservatory gay, and avoid as far as possible the expense of forcing, which is injurious to most plants. Be careful not to let plants in bloom suffer from want of water, giving weak clear manure water to Chrysanthemums, Salvias, Camellias, &c., and use every means to preserve the beauty of specimens in bloom as long as possible. Damp and mildew are the great enemies to be guarded against at present in conservatories and greenhouses; but these must be sharply looked after, especially in the case of plants which have not ripened their growth well and are in a rather soft state. Very little water will be required here at present, but the plants should be carefully looked over about twice a-week, so as to make sure that nothing is allowed to feel the want of it. If not already done, have plants tied into proper form with the least possible delay, for it is difficult to tie a plant so that it will not look somewhat stiff and unnatural, and the sooner all this kind of work is done the better the specimens will look when in bloom. —W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Grubs.—We are glad "J. W.," at page 298, approves of shallow planting, which we recommended. Once, when every plant seemed going, we pricked out shallow, then planted with a trowel in a shallow drill, so that we could fasten the plant well afterwards, and we almost entirely escaped. This, however, is not the experience of the market gardener alluded to last week, whose plants were devoured in the seed beds. Our own experience so far confirms the observation of "J. W." We are quite as much obliged to "Y. B. A. Z." for his corrections at page 307. We have no doubt that the grubs we have ourselves seen this season are the larvæ of the crane fly, but it is possible that, leather-jacketed as they are, they may, as our correspondent believes, be the larvæ of some dart moth. We have seen few of the crane flies, or daddy-longlegs, this season, but in previous years we could often have swept them up in a cool morning in shovelfuls. They seemed to have a fancy for benumbing themselves on smooth stone pavement. One of the difficulties in being quite sure of the enemy is that different food and different coloured earth make some difference in the appearance of the grubs.

Scarlet Runners.—Our Peas are nearly over, and we shall seize the first opportunity of taking away the stakes, turning over the ground where the row stood, and putting in some temporary plants of the Cabbage or Lettuce tribe, as all may be useful before the cold days of spring leave us. Our Dwarf Kidney Beans are still fair, but are yielding to the more fleshy Scarlet Runners, which are still quite green, and a mass of pods of all ages. Frequently one sharp night destroys all, so we have a lot of dry litter in readiness, which we shall throw over them when we expect a sharp night. With this precaution we have often had them out of doors far on in November. Our last Dwarf Kidney Beans under a little protection are setting and swelling their pods well. These often help us in the beginning of the dark days without any artificial heat. Care is taken now that the ground shall receive all the benefit of the sun to warm it.

Globe Artichokes.—These never came in earlier than they have done this season, owing, no doubt, to the mildness of the winter. The crop was far beyond the common, both for dishes and for preserving as bottoms; but all at once, even though the ground was not very dry, the yield seemed to cease a few weeks ago much earlier than usual, and the leaves to decay, leaving nothing but the bare flower-stalks, which were cut down and charred, or turned to ashes. The stools seem in good condition, but the young leaves scarcely show as yet. We find, however, on scraping the ground with our fingers they are all right. We began to fear that we had allowed them to bear too profusely, but we think now they will do well next year, and grow strongly enough. We shall ere long place a mound of dry earth over each stool, and then a little litter. Meanwhile, as one dread enemy, the white Convolvulus, had established itself in the ground, we have had the latter carefully forked over, and every root we could see taken out, and as the comparative inconspicuousness of the stools left wide spaces between the rows, after dunging the ground for the benefit of the stools, and scattering some burnt earth and ashes over the surface, we have planted Lettuces thickly down the centre between each row of stools. On each side of these Lettuces we spread a thin row of our burnt heaps, and we observe that not a slug, snail, or grub has yet dared to cross them.

In many families Globe Artichokes are little cared for, but in others they are considered a great delicacy. For ourselves, though not disliking them when well cooked, we consider them chiefly useful when a pleasant conversation is desirable during dinner.

We shall soon be obliged to fall back on the *Jerusalem Artichoke* tubers, to take their place, but we used so many last season, that we did not want to begin with them too early, either for dishes or soups, a great many being required for the latter. A piece in which we thought we had not left a root, came up almost as strongly as a piece carefully fresh planted. When the tubers are seldom used, a small piece of ground may suffice for years, and without the trouble of transplanting; but when used often and prized, a piece should be planted every year the same as Potatoes. Then the tubers cook more regularly from being all of the same age. We are rather surprised that pheasants here interfere little with the tubers, as in the north we have helped to plant them largely in open spaces in woods, and there the pheasants dug up the roots for themselves. Probably it may be they obtain something more substantial in the south, in the way Barley, Peas, and Indian Corn. When once speaking of the abundance of rats to an employer, we accidentally remarked that in a place where we once lived, a rat was a rarity. "A very good reason," retorted he, as he bolted off triumphantly, "a very good reason, they knew they would have starved there, as you would have done had you stayed much longer."

On clearing off Beans, &c., between bushes, we shall fork the ground over after rough-pruning, and plant thickly with any winter Greens left in the seed-beds, as they may be useful in spring, and if not wanted, are easily cleared off. It is always better to have enough and to spare, instead of having to make everything go as far as possible.

FRUIT GARDEN.

Much the same as before. We have gathered the greatest part of our fruit, as even late Pears began to fall, and they keep better if they are not frosted, and several mornings this week the thermometer was very near the freezing point. Our dwarf bush Apple and Pear trees that showed in their foliage a certain brownish tint, the result of the drought of last summer, are now to a considerable extent losing that dingy appearance, and as usual are bristling with fruit-buds. Of a few growing rather strongly, we shall nip the roots a little as soon as the fruit is all gathered. Root-pruned thus early, the trees will not suffer, and if we should have a fair amount of sun for a few weeks, the leaves, so long as they remain at all green, will

help to mature the fruit-buds. If the leaves flag we shall syringe or shade. During the summer we dwelt somewhat in detail on summer pruning, or rather pinching, as a means of regulating the growth and fruitfulness of a tree; but in addition, when we wish to concentrate as much fruitfulness in little space as possible, a little root-pruning will also be necessary.

To many enthusiastic holders of small gardens, this root-pruning is a matter they cannot master, though almost as simple as head or branch pruning. They look upon it, however, with something like dread, and for their sakes we shall mention some of the modes of securing fruit on trees soon after planting, and so as to render root-pruning seldom necessary.

We will first take the case where station planting is resorted to, and means are taken, either by flags or concreting 15 inches or so below the surface, to prevent the roots going down. Good concreting should be about 3 inches thick, and be made of clean gravel six parts, and one part of powdered quicklime, with just enough of water to lay it down of a thickish consistence. Then let it be made smooth and be allowed to dry before the earth goes on. Such stations should not be less than 5 feet in diameter. The bottoming is made to prevent the roots going down, as the deeper they are the greater the tendency to luxuriance of growth, and the shallower the roots the more within atmospheric influence, and the greater the tendency to the production of fruit buds. If such trees need root-pruning, it is easily applied beyond the concreting. The stations should at first be fully a foot above the ground level in the centre, as even with mulching the height will always be lessening. Trees intended for dwarfs, if thus planted, will yield fruit quickly, but will grow rather slowly, as the extreme of growth and the extreme of fertility are ever opposed to each other.

Many who have no great depth of soil, and that soil rather poor, are anxious to have dwarf trees without any bottoming, concreting, and as little as may be of root-pruning. In such a case we would fork over the shallow ground, collect the best surface soil into flat conical heaps, at least 15 or 18 inches above the general level, and this being made tolerably firm we would spread out the roots carefully 6 to 8 inches below the raised surface. In very inferior soils we have obtained fine, healthy, fruitful trees by this means, and that with little more trouble than giving a mulching of a barrowload of rotten dung every season, for if it was applied early in summer it was generally out of sight before the next summer came. The mulching kept the roots moist and near the surface. If the soil was very poor, we would add a little sweet rotten dung mixed with it, but if at all fair we would put no dung at all in the soil about the roots, but apply all the manure to the surface. In fact, in all old kitchen gardens we would prefer a barrowload of fresh soil from the sides of a road, &c., to any manure mixed with the soil. No plan could well be simpler, and results demonstrate that it will succeed.

One, perhaps, wishes for special reasons to obtain small maiden plants, and does not care for fruit for two or three years, but wishes to have good-sized fruitful trees established as quickly as possible. In this case we would not trouble ourselves at first with bottoms or raised stations; we would manure the soil and plant on the level, much as a nurseryman would do, who wants trees to sell instead of to fruit. We would encourage our trees by mulching and watering for a couple of years or so, so as to obtain a nicely furnished balanced top, whatever the mode of growth adopted; and then, as the growth most likely would be tolerably vigorous, in the end of the second or third season, say early in October, we would carefully take up the trees, losing as few roots as possible, never allowing a root to dry, and replant every tree so taken up before beginning with another, spreading the roots out carefully on a raised knoll, covering with about 6 inches of soil, giving a little fresh soil if possible, and applying the dung given in the shape of mulching. We have seen numbers of trees thus treated, that continued luxuriant enough to be healthy, and were fruitful for many years without needing any root-pruning, and but little pruning of the head. Of course there was the trouble of carefully lifting and replanting; but in such young trees that involved less labour than would appear at first sight. The object of the mode was first to secure rapid growth to form a tree, then permanent fruitfulness with but little trouble. When this mode was practised under our advice, and where drainage even was objected to, we had the ground deep-stirred to the subsoil, but the subsoil and the lower strata left as they were before; the trees continued fruitful, the opening of the subsoil carrying off stagnant water, and the mulching on the surface keeping moisture near enough the top to prevent the roots going down in search of it. Though well aware of the importance of drainage to prevent stagnant water lodging, we are convinced we are not sufficiently aware of the importance of deeply stirring the subsoil as an assistant to, nay, even as a substitute for deep drainage, and though aware of the importance of bottoming platforms or borders where there is a thin soil over deep, close clay, &c., we rather think that if called upon to form a large plantation of dwarf fruit trees, we should be satisfied with draining off stagnant water, deeply stirring the subsoil a season before planting; and then, if we could obtain no fresh soil, we would be content with collecting the best surface soil in mounds, and keeping the roots moderately moist, enticing them near the surface by mulchings. Last season mulchings would hardly prevent, in such a case as ours, the roots from becoming too dry; but the circumstances were exceptional, as will at once be seen when we state that for two months we had no clean water to go to, and were forced to cover up what we could not water.

Something will be gained if our readers see that by the simplest modes they can effect their object; only as respects fruit trees let us advise them to bear in mind, that of various modes, one may be as successful as the other when thoroughly carried out, but that the mingling of plans will often be attended with failure; also let them remember the simple fact, that the nearer the surface the roots of a fruit tree are, the more will it be studded with fruit buds, and that if the surface be kept rich and moist by rough mulching, the roots will be less likely to go down deeply in search of water. The mere raising of a mound does not necessarily cause it to dry sooner, and more especially if the surface is stirred or covered. In raised flower-beds we have often found, that from the very depth and openness of the soil, less water was required than in the case of those on the level.

ORNAMENTAL DEPARTMENT.

We are sorry the weather is becoming so much colder. The flower-beds and borders are still so fine, that we would like them to continue a month longer. As yet we have not taken up anything, but next week we must move cuttings, so as to have a place in a cold pit ready for Calceolaria cuttings; for, after all, discarded as they are in many places, the best tricolor Pelargoniums make a poor substitute for them, and as yet we find that nothing meddles with them. Proceeded with housing and potting, and expect a very busy week.—R. F.

COVENT GARDEN MARKET.—October 20.

Markets are still very dull and heavy, foreign importations being in excess, and trade for inferior goods being quite at a standstill. Large arrivals of Potatoes both coastwise and by rail, best qualities maintaining former prices.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*Mrs. M. S.*).—Brown's "Forester."

Seedling Antirrhinums (*A. D.*).—The plants are much too close together. We would thin out every alternate plant, moving with a ball, and either plant in a bed 6 inches apart, or in their permanent quarters. When too close together they become weak and bare at the bottom. The others we would not plant out until March, and then remove them with good balls, watering if the weather be dry. You will have a splendid bloom next year.

Pruning Roses (*Idem*).—To save the plants from being broken by winds, you may peg the shoots down, and dispense with pruning altogether, or merely remove the points of the shoots, or the pegs might be pulled up in March and the Roses then pruned. In this way they will be likely to escape injury from late spring frosts.

Roses for Northumberland (*W. B. R.*).—If you refer to No. 194 of this Journal, you will see a communication from the Rev. W. F. Radclyffe on the subject. It is too long to extract, but you can have a copy sent to you by post if you enclose four postage stamps with your address.

Climbing Devoniensis Rose Lifting (*Sandy Soil*).—This Rose, lifted a month ago and potted, may now be planted out against a south wall. The moving a month ago will not destroy the tree, though the shoots are somewhat shrivelled. It ought to have had a light sprinkling with water overhead, which would have kept the wood plump, moderate waterings being given at the roots.

Woodcut Engraving (*Agnes*).—Plants and every other object can be portrnited in a woodcut. We recommend you to have some lessons in wood-engraving from Mrs. Buchanan, 18J, Fleet Street, who would readily instruct pupils.

Cinerarias Diseased (*G. P.*).—From your description we should say your plants are infested with the orange fungus or mildew. It is very unusual on Cinerarias. Give more air and light, and dust the leaves on the under side with dry lime and flowers of sulphur in equal proportions.

Wintering Pelargonium Stella (*A Constant Reader*).—To make standards they must have clear straight stems or strong shoots of the required height. If the stem is not straight it should be brought as nearly as possible to a perpendicular direction by securing it to a stake. All the side shoots on the stem up to the desired height should be cut off closely. The plants may be wintered in a dark cellar in dry sand, picking off all their leaves, examining them occasionally, and removing any mouldy parts. Frost must be excluded. Let the plants be dry before placing them in the cellar. If put in wet they will certainly become mouldy. Remove from the cellar and pot, placing in a gentle hotbed. They would be better wintered in a greenhouse.

White Bedding Plant (*A. B.*).—The common white Sweet Alyssum would suit your purpose, but white Verbenas would be better. If your Pelargoniums and Calceolarias are strong, white Feverfew would also do if well pruned. The Alyssum is much stronger-growing than the Variegated.

Bignonia radicans not Flowering (*Idem*).—Prune away a lot of the small little shoots, leave those of moderate growth, merely nipping the points out, place them close to the wall, and give the sun a chance to ripen them. If these shoots are ripened, they will throw out short flowering shoots from the buds. If the plants make weak wood, thin them and give rich top-dressings.

Forming an Oval Bed (*M. D., Balham*).—To make an oval when the length is given, divide the long diameter into three equal parts. From the two inner points describe two circles, which circles will form the ends and main bulk of the oval. The points where the two circles meet, or cross each other, will form the centres to connect the ends and sides of the oval. A gardeners' oval is generally thus formed on the ground. The longest diameter is marked out by a cord. It is then bisected in the middle by the shorter diameter, it being thus divided in two. Then take the half of this short diameter and divide that into three equal parts, and set off the length of one of these parts from each extremity of the diameters. Place a cord round these pins, but so loosely that when stretched with a stick it will come to the extremity of the diameter. We generally do one side, then turn the string and do the other side. This is, perhaps, the easiest plan when length and breadth are given. Thus if an oval is 90 feet long, and 60 feet wide, the third of half the short diameter is 10 feet, and, therefore, the pins must be 10 feet from the ends of the diameters.

Packing Ferns (*E. L. J.*).—They would travel best in a box or case, each plant being placed in water so as to have the soil well wetted, and then cover the root with damp moss secured with twine or matting. Place them in the box (a shallow one is best), layer by layer, filling up the intervals with dry moss, and placing a layer of moss between. Any kind of dry material will do for packing in, as chaff or anything light. The tree Fern trunks, the *fronds* being cut off, may be packed in a similar way, and in a long case as required. Though they may come to hand somewhat enfeebled they will speedily recover in a genial temperature and moist atmosphere, soaking the root part well and sprinkling the stems with water twice or thrice a-day.

Fountaine's New Method of Growing Fruit.—The Rev. John Fountaine has sent us specimens of Transparent Gage, Reine Claude de Bavay, and Braby's Green Gage Plums, as well as two Nectarines. The last-named were small, but the Plums were fine, and all excellently ripened and full-flavoured.

Seed Potatoes (*L. Wren*).—We prefer for sets middle-sized whole Potatoes, after cutting off their crowns, either to small Potatoes or cuttings of large ones. We sent your query to a well-known Potato-cultivator, but have not received his reply.

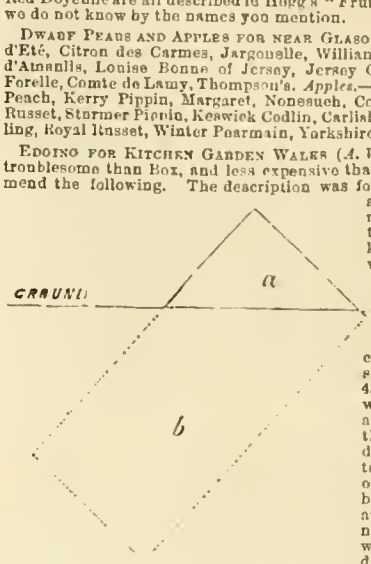
Seedling Potato (*R. Headley*).—In shape the tubers resemble those of the Fluke. They are like them also in flavour, but are more mealy.

Keeping Walnuts (*M. E. Cartwright*).—Put them in layers alternately with damp sand, in jars bunged tightly and kept in a cold cellar.

Pears (*J. Huish*).—Forelle, or Trout; Sucrée Vert, or Green Sugar; Beurré Duval; Doyenné Blanc, or White Doyenné; and Doyenné Gris, or Red Doyenné are all described in Hogg's "Fruit Manual." The other two we do not know by the names you mention.

Dwarf Pears and Apples for near Glasgow (*S.*).—*Pears.*—Doyenné d'Eté, Citron des Carmes, Jargonelle, Williams's Bon Chrétien, Beurré d'Amanlis, Louise Bonne of Jersey, Jersey Gratioli, Monarch, Hessle, Forelle, Comte de Lamy, Thompson's. *Apples.*—Cellini, Early Julien, Irish Peach, Kerry Pippin, Margaret, Nonesuch, Court of Wick, Syke House Russet, Stanmer Pippin, Keswick Codlin, Carlisle Codlin, Dumelow's Seedling, Royal Russet, Winter Pearmain, Yorkshire Greening.

Edging for Kitchen Garden Walks (*A. W.*).—For an edging "less troublesome than Box, and less expensive than terra cotta," we recommend the following. The description was forwarded to us some years ago by Mr. Robson. "For many years I have been in the habit of using common kiln bricks as an edging to walks through dark shrubberies and similar places. These are laid in a diagonal position—one edge and one flat side presenting each an angle of 45° to view, or, in other words, they are laid with an angle-edge upwards, thus — and, being placed deep enough in the ground to allow only about 2 inches of the angular side of the brick to be seen, its appearance is pleasing, and it is not easily moved; even a wheelbarrow driven over it does no further damage than chipping the angles off a little; and sweeping and all the other ordinary work of cleaning a walk only improve its appearance."



a The corner of brick forming the edging.
b The buried portion of the brick.

Vine Grafting.—"A Reader" would be obliged by "R. M. W." stating what degree and source of heat he has used in the production of the Grapes he mentions; if such Grapes are grown upon pole Vines, in borders or pots, and how many rods from each Vine stool, and whether rod and spur or long rod—that is, successional rod—pruned.

Aspect of Vine Border (*E. M.*).—Of the two, east and west, we should prefer an east to a west aspect, as the east is the drier. Borders with a west aspect are very apt to become saturated by the autumn rains coming from the westward.

Mrs. Pince's Muscat Vines (*A. F.*).—Lift them and plant them in the vinery where they can have heat. They will ripen their wood there, which they do not do in your orchard house.

Vine Leaves Blotched (*A Vexed Grape-grower*).—We have examined the Vine leaves carefully and can find no trace of any disease on them. We thought we saw traces of red spider, but even with the help of a magnifier we could not discover it. The blotched appearance of the leaves whilst the wood is green, we attributed to scalding—the effects of accumulated hot vapour in the house—from air-giving being delayed in the morning; but it may rather be the result of your treatment. "We have used sulphur and tobacco-paper for fumigating (grow flowers and Ferns in the house), and in no instance has the sulphur fired. The bed we believe to be in good condition and well drained." What puzzles us here is, that you say nothing about the Ferns, as very slight sulphur fumes are soon felt by them, and the heat that would consume the tobacco-paper, though without burning in a flame, would be too powerful for the sulphur fumes to be safe. In fact, sulphur fumigation should never be practised where there are growing plants. If the plants were near the floor they might escape, whilst the leaves near the roof were affected. We shall judge that one of these caused the evil, if the house was most affected near the apex. The "Vine Manual" will suit you, and may be had from our office, by post, for 2*s.* 8*d.*

Ashes *versus* Tan for Plunging (*E. G.*).—Ashes we consider the better, as they are drier and have an advantage in not harbouring worms. They answer equally well for plunging pots in or for banking-up outside the frame to keep out frost. Tan, however, is a good material for the latter purpose.

Heating with Hot Water (*A. Z.*).—Such a mode, having return-pipes beneath the level of the bottom of the boiler, has been made to answer by having air-pipes from the lowest parts, but it ought never to be tried if it can be avoided. If the pipes cannot be raised, the boiler should be sunk so that every pipe shall be above the level of the boiler. Portland cement will do well enough for the joints of pipes if they do not slope very much. Where there is a great perpendicular pressure we would prefer lead or iron-dlings for joints. The most if not all the joints at Woodhall were made by Mr. Beale with Portland cement, and no joints could stand better.

Extent of Hot-water Pipes Needed (*J. E. T.*).—For your house

span-roofed, 18 feet by 12 feet, you would need at least 90 feet of 3-inch piping. We would prefer 110 or so. We think a terminal saddle-back boiler would suit you best, and if it has a surface equal to 4 square feet exposed to the fire it will be sufficient. For that purpose alone a small one would suffice, but it is well not to have too small a boiler. Almost every bricklayer will set such a boiler well.

Composite Glass-house (*W. T.*)—For such a house to be used in parts, as greenhouse, orchard house, and vinery, we would prefer a span-roof, and to run north and south, or in these directions, so that one side of the house might have the morning, and the other the afternoon sun. Of course, such a house will be colder, more exposed to the weather than a lean-to with an opaque wall at the back; otherwise the span is the best.

Pelargonium (*C. A. G.*).—The name is derived from the Greek Pelargos, a crane, on account of the seed vessel and its appendages resembling the head of that bird. The distinction between Pelargonium and Geranium is fully detailed at page 431 of our last volume. Camellias are best propagated by grafting, the time for doing which is from September until February. The Manetti Rose was named after M. Manetti.

Burning Clay (*W. J. D. P.*).—At page 122 of our last volume there are directions for burning clay for making walks. The same mode answers for improving clayey soils.

Moving Pampas Grass (*H. Garden*).—You may safely remove the Pampas Grass which has been planted nine years, doing so at the end of March, preserving a good ball, and watering copiously in dry weather. A young plant, however, would do better.

White Jasmine Pruning (*Mary*).—It is best pruned at the end of March or beginning of April, but the wood should be kept moderately thin and secured to the wall, so as to have it well ripened. The summer pruning should consist of thinning-out the shoots where too close together, so as to expose them fully to light and air, not shortening them, as the flowers are produced from the points of the shoots. Except in warm situations, the plants do not flower in the open ground. A wall with an east, west, or south aspect is required.

Mandevilla suaveolens Planting (*A Subscriber*).—The stem, for 3 feet of its length, would, were you to plant it in the outside border, be exposed to frost, which we fear would destroy it; besides, we do not think it would succeed, the roots being so much colder than the shoots. We have grown it well in pots, and do not see why you should not succeed well with it grown that way.

Plant for the Back Wall of a Greenhouse (*Edward Barton*).—Probably no plant is so fine for a wall as Luculia gratissima. It is not a climber, but a plant of free growth, and autumn and winter-flowering, the flowers being fragrant. It would not succeed if the roof is much shaded or covered with Vines. An Orange tree would do very well, the flowers being very fragrant, and the fruit very ornamental and useful. You would need two Orange trees and a Lemon in the centre. Those are what we advise. Hoya carnosa is a climber and suitable. The flowers are fragrant. You may obtain them of any nurseryman.

Planting Strawberries (*Novice*).—The plants should have the rows 2 feet apart, and the plants should be 18 inches from each other in the rows, though you may have them the first year half that distance apart in the rows, and then thin out every alternate plant. Being in pots we would not plant out until the beginning of March, taking advantage of the interval to have the ground well trenched, manured, and exposed to the action of frost by throwing it in ridges and forking it over in dry frosty weather.

Coleus Cuttings (*Idem*).—Pot them off into 4-inch pots, and they will make nice plants for table decoration through the winter, and furnish a number of cuttings in spring. A compost of two parts fibrous loam, one part leaf soil, and one-sixth of silver sand will grow them well.

Worms in Pots (*J. A.*).—The plants you name will not bear the lime water. Try the soda solution as recommended for lawns in last week's Journal of Horticulture.

Ink for Zinc Labels (*A Subscriber*).—Sal ammoniac powder, and verdigris, each 1 drachm; lampblack half a drachm, mixing with 10 drachms of water. It forms an indelible ink for zinc labels.

Liliums in Pots (*Idem*).—For three bulbs 8 or 9-inch pots are suitable, 7-inch pots being suitable for single bulbs. A compost of two parts fibrous loam, and a part each of leaf soil and sandy peat will grow them well. Fill the pots half full of soil, then introduce the bulbs, covering about an inch over the crowns. Fill the pots to the rim when the shoots have grown a few inches higher than it. All should be potted forthwith, plunged in coal ashes in a cold frame, and protected from frost in severe weather. Keep the soil moist.

Bulbs, Planting (*Idem*).—All the bulbs you name should be so planted that their crowns will be 1½ inch below the surface, and not more than 2 inches; top-dress with leaf soil an inch or so thick. It will be gone by spring.

Tweedia cærulea Treatment (*J Bayly*).—A compost of equal parts sandy fibrous loam, leaf soil, and sandy peat is suitable, with good drainage. It likes a light airy position, and to be kept dry in winter. Probably you keep it too warm. It only needs a cool greenhouse, or one from which frost is excluded.

Weeds in Gravel Walks (——).—The best plan is to asphalt the walks. It is best done in dry weather, but you may asphalt them at this time of year during dry days. It is well to have a good bottom of rubble, and then cover with 3 inches of asphalt, formed by pouring boiling coal tar over cinders bringing the whole to the consistency of mortar, and when this is spread on the walks and stiffens a little, sprinkle with gravel—spar is best—and when it will bear the roller, roll it firmly. Coal tar answers quite as well as pitch, and may be had at a cheap rate from gasworks. At some it is given away.

Vallota purpurea Potting (Y.).—The best time to repot it is early in spring before the bulbs become active, but potting may be performed at almost all times, except when the plant is growing and flowering.

Names of Fruits (*Centurion*).—Your Pears are pretty correctly named. 1 is Bon Chrétien d'Hiver; 2, Crassane; 3, Emile Bivort; 4, Duchesse de Brabant; 5, Colmar Van Mons; 6, like Belle Après Noël; 7, Doyenne du Comice. (*A Fifteen-years Subscriber*).—1, Hacon's Incomparable; 2, Beurré de Capiaumont; 3, Calebasse Bosc; 4, Beurré Diel; 5, like Beurré Brattoneau. (*Apple Grub*).—*Apples:* Tower's Glory; 2, Bath Apple; 3, Lyscorn; 4, Dutch Fullwood; 5, unknown; 6, too scrubby to recognise; 7, Cockpit; 8, Beurré Diel; 9, Marie Louise. (*W. Pethick, Bristol*).—Your Grape, as far as we can judge from the two berries sent, is Black Alicante. (*E. W.*).—These, unfortunately, had got into confusion ere they reached our hands, the numbers being misplaced, and in most cases wanting altogether, so that we have nothing to enable you to identify them. The Apple is Emperor Alexander, the highly-coloured Pear is Beurré Clairgeau, the long russety one Maréchal de la Cour; another is Beurré Diel, another Urbaniste.

Names of Plants (*Byron, Devon, and others*).—You sent leaves only. (*A. E. J.*).—Salvia Grahami. (*J. Bryan*).—1, Santolina incana; 2, Solidago elongata; 3, Polygonum affine; 4, Lavendula dentata. (*C. S., Bath*).—1, Adiantum tenerum; 2, Pellæa cordifolia; 3, Adiantum capillus-Veneris. (*W. Hodgson*).—Sphagnum cymbæfolium. (*A. Subscriber, Conway*).—Lobelia fulgens. (*A Six-years Subscriber*).—You only furnish us with leaves, consequently we are unable to give you much information concerning your unknown kinds; but Nos. 1 and 4 do not appear to be Ardisias, and the little spiny Solanum, No. 11, we do not know. We should be happy to receive the "Hoya Matotszki" when in bloom; its foliage reminds us of H. paraasitica or H. lacunosa. We should not suppose the variegated forms of Ixora javanica, Thea Bohea, Euonymus radicans, and the common Oleander to be new.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending October 19th.

POULTRY, BEE, AND PIGEON CHRONICLE.

DORKING BANTAMS.

At the Chelmsford Poultry Show last week were two pens, in the one a White Bantam cockerel, and in the other a pair of pullets, having five toes and all the other characteristics of the Dorking. The variety, for such it is, excited much attention, and seemed to be unknown alike to judges and exhibitors. One of the judges considered them merely as White Bantams with five toes, alleging that every kind of domestic fowl will occasionally throw the fifth toe. But it has been stated that "Bantams of all kinds are merely domesticated varieties that have been reared and rendered permanent by the care of man."

These birds were exhibited by Mr. G. Howes, of Longstowe Hall, Cambridgeshire. He has bred them for about eight years, during which time they have very rarely thrown birds without the fifth toe, and not more frequently than is the case with Dorkings themselves. For the most part they throw the rose comb, both the rose and single comb being common also to the White Dorking.

Mr. Howes has kindly given me the following particulars which are all that he knows of the origin of the variety, or from whence he obtained them. He remembered buying some White Bantams and some eggs, about the same time, from Cambridge and from Lichfield. The man at Cambridge says the White Bantams did not come from him. The man at Lichfield is dead. The latter was a dealer in poultry, but used to have eggs and poultry sometimes from Holland. The White

Bantams were allowed by Mr. Howes to run in a yard with Dorkings.

There is, therefore, every reason to suppose that this is a new and distinct variety of Bantams, which can be called by no other name than Dorking Bantams; and they are as much entitled to it as the Game Bantam, which is the result, in the first instance, of a cross between a small Game cock and a Bantam hen.

The birds exhibited were unusually small, even for Bantams, but they were not well shown as to condition, and the legs of the pullets did not match well.

Perhaps some of your readers may have met with this kind elsewhere, and if so, it would be interesting if they would send to you the particulars of its breeding.

The birds in question, then, may have been produced by an accident, but they have now for several years been reared and rendered so far permanent by the care of Mr. Howes.—GEORGE MANNING.

AUCTION AT THE BIRMINGHAM POULTRY EXHIBITION.

I QUITE agree with Mr. Wood that the time for the sale of birds at Birmingham is too early on the Monday, but I also think Monday is the wrong day for the sale. Clergymen will not perhaps, at least do not like to travel on Sundays; besides, there are many others living at a greater distance than Mr. Wood, who could not possibly arrive at Birmingham in time on the Monday. From this county some will be there, and will go on Monday; they will not be able to be at Bingley Hall before 2.30 P.M., at the earliest, or three hours and a half after the sale is stated to begin. Again, if the sale were fixed for Tuesday, we should have time to look the birds over on the Monday, to make our comments upon and notes for which birds we should bid; it would give everyone a more equal opportunity, and there would be a greater competition.—HENRY P. LEACH, *Woolpit, Suffolk.*

THE LONDON POULTRY SHOW.

THE adjourned meeting for the purpose of receiving a report from the Committee appointed at the last meeting, took place on Tuesday last, Mr. Esquilant in the chair. Mr. Crook, Hon. Secretary, stated he had received promises of money towards the guarantee fund and expenses to the amount of £150. The estimated expenses would be about £450, and the sum expected to be received from all sources would probably reach the sum of £420, leaving a deficit of £30. This, or any further outlay incurred would, of course, have to be paid by the Committee, besides the amount already guaranteed by each member. In this estimate the Committee had entirely ignored the prizes and entries, as they only expected the latter to pay the prizes.

After some discussion as to whether the Committee would be justified in commencing operations, so that a show might be held this year, it was finally resolved that it should take place simultaneously with this year's Cattle Show, and that £300 should be offered for prizes, also that the Corinthian Bazaar, Argyll Street, be engaged for that purpose.

The Exhibition now seems to be thoroughly started, and with every prospect of success; but we hope some more gentlemen will allow their names to be placed amongst the guarantors. It was noticed that not one Rabbit-breeder or exhibitor had his name on the guarantee or prize-list fund. We are surprised at this, especially as we have published so many letters from correspondents complaining of injustice towards their favourites. No doubt they will at once come forward with assistance, or it is likely no prize will be offered for Rabbits.

Mr. F. Crook, Vine Cottage, Forest Hill, S.E., was appointed Honorary Secretary, to whom all communications are to be addressed.

[Since the above was in type we have been informed that the Corinthian Bazaar cannot be engaged on suitable terms, but steps will be taken to secure another place of exhibition.—EDS.]

I REJOICE exceedingly to see in your columns that it is proposed to hold a poultry show in London. While all the large towns and very many small ones hold annually a successful exhibition, London alone has nothing of the kind; and yet in and around London are a host of gentlemen and ladies who take an interest in "cocks and hens."

Within a radius of thirty or forty miles of the metropolis reside several of the leading breeders and exhibitors, and at many a suburban villa may be seen from the passing railway train valuable specimens of poultry. The metropolis can boast every advantage of railway access, and also several convenient localities for a large exhibition. In London reside more than one of the best known poultry judges. Surely, with all these advantages, London may undertake what many a Yorkshire village already boasts—namely, an annual exhibition of poultry. An active and able committee will doubtless make use of all these advantages, and insure the success of a show worthy of the place where it is held.

The week of the Cattle Show seems a very suitable time, and if the locality chosen for the poultry be not far from the scene of the Cattle Show, many who come to see the latter will pay to see the former also. We may count, moreover, upon hundreds, including many of the fair sex, who would never take the trouble to visit a show of fat beasts, flocking to see some of the best poultry in England gathered together for competion in the metropolis.

In conclusion, let me state that I shall be glad to add my mite to the subscription raised for the purpose.—JOHN PARES.

OUR POULTRY SHOWS.

POULTRY shows are just now receiving a large share of public attention and support, and I wish, through the medium of "our Journal," to call attention to one or two things in connection with them, which are unfortunately on the increase, and which must ultimately, if not checked, destroy much of their popularity. I allude to secretaries and committeemen competing for prizes, and to local exhibitors being allowed to compete with the same birds for both local and general prizes. This was notoriously the case at the late Long Sutton Show, where we find a local exhibitor, who is a member of the committee, taking the very modest number of four silver cups with two pens of birds. Now, this is manifestly unfair to the other exhibitors who do not reside within the limits of certain villages near Long Sutton; and why should local exhibitors have two chances of a prize to other exhibitors' one? The time has arrived when exhibitors should make a stand against such practices, and I hope that committeemen generally will see the desirability of refraining from competing, and of confining local exhibitors to local prizes, or most assuredly our poultry shows will not hold their own, as exhibitors will not care to send their birds to any show where these practices are allowed.—JUSTICE.

PRIZES FOR HOUDANS.

IN reference to the suggestion which has been made by some of your correspondents, that a class should be reserved for Houdans separately from other descriptions of poultry, I wish to add my mite of recommendation. Certainly Houdans are worthy of the distinction, whether we regard them as egg-producers or as ornamental poultry merely: and, indeed, while about it, the Crève-Cœurs might also be similarly favoured. The object of the promoters of exhibitions of prize poultry is, undoubtedly, to interest as many poultry fanciers as possible, and omitting to give a separate class for the fowls I have named, will shut out many from participating in the enjoyment which such gatherings afford.—J. H.

JUDGES EXHIBITING AT THE BIRMINGHAM POULTRY SHOW.

I TRUST this year we may be spared the spectacle of judges exhibiting in the poultry classes at Birmingham. Without wishing to impute that anything unfair has occurred in the past, it must be admitted such a proceeding cannot be justified. The judge who exhibits is brought constantly into contact, both before, during, and after the judging, with his brother judges, and however honourable or upright he may be, there are persons who imagine that a hint may be given as to particular birds. This practice has not been in existence more than two or three years, and ought never to have been permitted.—A. B.

THE SOUTHAMPTON POULTRY AND BIRD SHOW.—The entries for this show close on Thursday, the 28th inst. We are informed this will prove one of the most successful meetings of the season.

The prizes have been greatly increased this year; several valuable extra cups are offered, and when it is considered that one pen of poultry has the chance of winning prizes to the amount of £22, there can be but little doubt of the show being well supported. The prizes for Pigeons, cage birds, &c., are good.

DEAR'S GAME CHAMPION CUP.

This cup, manufactured by Mr. J. W. Benson, Ludgate Hill, is of silver, very solid, very handsome, and is gilt inside. The form is Etruscan, and the cover is appropriately surmounted by a Game cock. On one side is this inscription:—"Dear's Champion Subscription Cup, for the best Pen of Black-breasted Red Game Chickens. Hampshire Ornithological Association." This cup will be competed for at the Hampshire Ornithological Association's Exhibition, commencing on the 9th of November next at Southampton. The cup has been subscribed for by some of the most celebrated breeders of Game, among them being Messrs. Dear, Hodgkinson, Stagg, Ames, Fletcher, Gibson, Parkin, Matthew, O'Grady, Russell Hall, Rigden, and Loe.

OAKHAM POULTRY SHOW.

It is far from a pleasant task to criticise the arrangements of gentlemen who undertake the oftentimes thankless work of getting up a poultry show; and yet these criticisms, if given and taken in a proper spirit, cannot but be productive of good. I remember last year that complaints appeared in your Journal respecting the Oakham Show. It is clear, from the notices in the prize list just issued, that the committee are anxious not to give occasion for grumbling this year; and yet I would suggest that in one respect there is room for improvement—namely, in the time the birds are expected to remain at Oakham. They must be there not later than 7 A.M. on Tuesday, the 23rd—*i.e.*, they must travel, if sent from any distance, on Monday, and they must remain until 9 A.M. on Friday, the 26th—*i.e.*, they will not return home until some time on Saturday. Only those who have shown good birds know what this means, and as an exhibitor who has won a very fair share of prizes this year, I can assure the managers that I should not think of exposing my birds to the risk such a lengthy detention involves. Why not have them in on Tuesday evening, judge them on Wednesday until one or two, and send them home on Friday evening?—A Prize-Winner.

CHELMSFORD POULTRY AND PIGEON SHOW.

Under the skilful management of a very careful Committee, this meeting has greatly increased in public estimation; so much so, indeed, that the number of pens exhibited this year was nearly double that of only a couple of years back. A single glance at the printed catalogue shows that poultry and Pigeons from almost every principal breeder in the kingdom were entered for Chelmsford. In the hope—though it indeed appears almost time and trouble misapplied and disregarded—of directing the attention of owners to the folly of forwarding birds by the last train, we again record that a very large number of excellent pens were delivered at the Chelmsford Corn Exchange considerably after midday, and consequently long after the Judges had returned their awards. As many of these pens had travelled several hundreds of miles to the Show, the money loss to the owners must have been very considerable, and the vexation still greater. We again urge, "*never trust to the last train for the transit of poultry to any exhibition.*"

Although the Corn Exchange is large and exceedingly well adapted for the purposes of a poultry show, this meeting promises ere long to quite exceed the dimensions of the building. This year, having a double tier all round, and a double tier of pens placed back to back down the centre, was unavoidable, so great was the increase in the number of the competitors; and the general appearance of the Show on entering was unusually excellent.

Grey *Dorkings* were the first class in the catalogue, and they afforded quite a treat to any breeder; they were, in fact, throughout superior. The *Game* classes were good, the Black-breasted and other Reds more particularly so. The Buff and Partridge *Cochins* were much superior to the White ones, with the exception of a few special pens of the latter. The *Spanish* were the best classes of chickens we have seen this season; and in respect to the *Brahmas*, whether Light or Dark-feathered, it is impossible to speak more highly than they deserved. Forty pens of Light Brahmas were exhibited. Although somewhat select as to numbers, the *Hamburghs* were generally good. The *French* fowls had a class to themselves, which was remarkably well filled, some of the chickens being exceedingly early and well matured. The Game *Bantams* of this year greatly surpassed any that had been shown at preceding Chelmsford shows. It was in *Ducks*, *Geese*, and *Turkeys* that the highest position was attained, and as it may interest many of our readers, we give the weights of the heaviest pens. The pens each consisted of a pair—male and female. Turkeys, 31 lbs. 9 ozs.; Geese, 44½ lbs.; Aylesbury Ducks, 16 lbs. the couple. Any of our readers who can remember the poultry of some thirty years back, will thus be able to estimate the important national benefit that has arisen from exhibitions as regards the utility of poultry for table purposes, altogether irrespective of the home pleasures of their production, and the even greater satisfaction of seeing the best breeds in the country in open competition, side by side.

The *Pigeons* were, without doubt, a chief feature of the Show, and though the bulk of them were in heavy moult, a number were in plumage that could not have been exceeded even at spring time.

Another unusual feature of the Show was a class for pairs of dressed chickens, and a similar one for Ducks. We append the weights of three pairs of each as they lay for exhibition:—Chickens, 14½ lbs., 13 lbs. 15 ozs., and 13 lbs. 10 ozs. Ducks, 10 lbs. 10 ozs., 10 lbs. 1 oz., and 9 lbs. 13 ozs.

The day of the Exhibition was remarkably fine, and the attendance was most satisfactory. We published the prize list last week.

(*From a Correspondent.*)

Dorking cockerels stood first, but these hardly seemed to be so good as I expected to find them. The pullets were decidedly better. *Game* were next. The Rev. F. Watson was first and second with two capital birds. I preferred the second one, as he appeared to be a more promising bird, but the difference was so slight that it must have puzzled the Judges on which to decide. *Cochins* were numerous and good. Mrs. Woodcock's two Buff pullets, and Mr. Sidgwick's cockerel and two pullets in the "Any variety" class, were especially worthy of notice. Mr. James was first in *Spanish*, with a splendid fellow possessing a beautiful white face, good comb, very long in the ear-lobe, and in capital feather. The second was also a very good bird, but slightly deficient in the comb and almost without a tail. Pullets were good, but the second prize was awarded to birds hardly deserving of it. Those highly commended were certainly whiter and larger-faced than their more fortunate rivals. This breed does not appear to be very fashionable in Essex, for out of the thirteen pens exhibited nine were sent from London.

The pride of the Show were the *Brahmas*, which were magnificent; they alone were worth the journey to see. Many only mentioned here would have gained a prize elsewhere. The first-prize Dark cockerel was hardly in feather, but he will make a grand bird. The Dark pullets were equally good. In the Light class a silver cup was offered for the best cockerel; this was awarded to Mrs Williamson's beautiful bird. For Light pullets, Mr. Crook was first with two which were very handsomely marked. I did not notice one bad bird in the whole of the Brahma class.

Hamburghs were few in number. Mr. Pickles took the first prize for pullets, Silvers. These would have been perfect if a little lighter. In the *French* varieties I noticed a cock which was certainly not hatched in this year, whose age was stated in the catalogue to be eight months. I was glad to see written on the ticket number, "disqualified—old bird." In the class for "Any distinct variety," pullets, were some good Polands. These arrived "too late for competition." What a pity it is to find exhibitors waiting until the last train, and after all the expense and trouble, shutting themselves out of the competition.

The Black and Red *Bantams* were a fine class, especially the first-prize bird, which by-the-by had a narrow escape of losing the prize, and, perhaps, his life. He belonged to Dr. Webster Adams, of Ipswich. On the doors being opened to the public in rushed that gentleman to see what prizes his birds had won. Judge his surprise on finding no bird in the pen. He soon commenced making inquiries, but was told it had not arrived. The doctor knew better. He hunted for the basket, which was soon found beneath the pens. There was the bird alive and well, and a little beauty he was. Had not Dr. Adams been present, he would undoubtedly have lost the prize and, perhaps, the bird. How careful ought Secretaries to be in ascertaining if all the baskets have been examined, especially when there is an empty pen. Game Bantam pullets were also good.

Rouen *Ducks* were very good; the first-prize pair were very large and in excellent condition. Aylesbury Ducks not quite so good. Some of the *Geese* were immense. *Turkeys* were a good class.

In the selling classes there were to be found some excellent birds, equal, if not superior, to some of those which had been awarded prizes.

Pigeons made a good show, far better than at any other exhibition held at Chelmsford. For Carriers, Mr. Wiltshire was first with a splendid bird. Ponters were hardly in feather. Here Mr. Fulton was first, as he was in Tumblers. Jacobins were uncommonly good, particularly Mr. A. Van der Meersch's Reds, which were first. Fantails were numerous and good; Barbs a magnificent lot; Trumpeters a very good class. In the "Any variety class" there were some beautiful birds.

This was a very well-managed Show, the birds were well fed and looked after, but I must condemn the system of allowing certain privileged people to claim birds before shows open. Before the public were admitted many birds had been disposed of. This, to say the least, is very unfair, and will, no doubt, be rectified in future years. Now, a question as to committees generally. How is it they take so

long in sending the prizes after the show is over? From some shows held more than two months ago, the prize money has not yet been sent, nor even the money for birds sold at the time. This is very unbusiness-like.—An Amateur.

TASMANIAN POULTRY SHOW.

The fifteenth annual show of poultry and song birds, held under the auspices of the Tasmanian Poultry Society, was opened August 10th in the Town Hall. The Show was one of the largest yet held in Hobart Town, and the spacious hall and ante-rooms afforded abundant space for the proper display of the exhibits without inconveniencing the promenaders.

Including those sent in for exhibition only, we counted over 270 pens and cages in the Show, a great display for Hobart Town. The exhibits embraced fowls of every class, Turkeys, Geese, Ducks, Pigeons, Canaries, and song birds in great variety, besides Pheasants, Rabbits, and miscellaneous live stock, including a kangaroo.

Beginning at the hardoor department, *Dorkings*, *Black Spanish*, *Cochin-Chinas*, *Brahma Pootras*, and others of their kind were exceedingly well represented, and many of the specimens were of the very first quality, the prize-winners in the respective classes being greatly admired. The Shanghaes especially were in excellent feather, of good colour, and perfect wonders in size. They reminded us of the first specimens of this kind of fowl shown in Hobart Town, which were entered some years ago by Mr. Thomas Paterson, a gentleman whose name we were sorry to miss from the entry list. The *Game* fowls exhibited were below the average, and for these birds, which have generally formed an attractive feature of the show, the season seems to have been somewhat unfavourable. The *Game Bantams*, particularly the Duckwings, were exceedingly beautiful, and formed a most attractive feature of the show; they were in very fine plumage, and nearly all worthy of honourable mention. There were nine pens of *Turkeys*, but we cannot refer to them as of more than medium excellence. One pen of pure white, being curiosities in their way, were greatly admired.

The waterfowl were not very numerously represented. A couple of pens of very fine *Geese* were shown by Mr. Perry, being hybrids, the produce of the African Geese imported by Mr. Graves, and the good old grey Goose of England. Mr. Perry was the fortunate purchaser of a pair of African Geese at the Peoples' Auction in aid of the Franklin Island Fund, and the noble birds shown represent a portion of the profits of his speculation. There were two or three pens of Aylesbury Ducks shown, but we cannot speak of them very highly; they were of good size and pure in colour, but their condition did not entitle them to rank as first-class specimens of this famous breed. A pair of very pretty Maori Ducks, exhibited by Mr. Alderman Belbin, attracted a great deal of notice, and were much admired. Before leaving the waterfowl, we must not omit to mention a pair of very fine Cape Barren Geese exhibited by Mr. J. W. Graves. These beautiful creatures are natives of Cape Barren, and are peculiar to the region of Bass's Straits. They are now becoming almost extinct, and it is to be regretted that some protection is not afforded to them by our Native Game Act. They are remarkably docile and affectionate, and the gander shown, who rejoices in the name of Darby, follows his owner about like a dog, and perambulated the room several times, allowing the children to pat and make friends with him.

The Hon. Mrs. Du Cane was the exhibitor of three fine English Pheasants, a cock and two hens, which were much admired.

The Pigeons were a great feature of the show, and there were upwards of seventy cages exhibited, embracing nearly every variety: Baldheads, all colours; Yellow Beards, Blue Beards, Pouters, Tumblers, Turbits, Almonds, Carriers, Archangels, Jacobins, Barbs, Nuns, Kites, and others in variety too numerous to particularise. A pair of Lachlan Pigeons, exhibited among the Doves, resembling a good deal the Crested Pigeon of the marshes, were very greatly admired. In the first ante-room there were twenty-six cages of various song birds and Parrots, and twelve pens of Rabbits.—(*Mercury.*)

RABBITS AND THEIR VARIETIES.

I have been from home, but on my return, upon looking over "our Journal," I was delighted to find so much information had been given in reference to both Rabbits and their judges; all tending, I hope, to bring about a more satisfactory state of things. If this should be the case, the result will be an increased number of entries at all shows where it is known that a competent judge will award the prizes. I have been much pleased with the valuable information given in these pages week after week respecting poultry, Pigeons, and bees, and as regards these, various points in dispute seem now to be permanently settled. For instance: the Houdan controversy respecting his red feathers, or his having only four claws, is now quite understood; and of Pigeons, the points are now fully understood, and the stamp of perfection must be upon the birds before they can be at all in favour with the judges whose critical eyes detect the least defect. I would ask, How is it that such a knowledge of the points of merit is acquired? I would give the old-fashioned but true answer—"By study of the subject." When fanciers of Rabbits can feel the same confidence as those of poultry or Pigeons in sending their pets to shows, they will be satisfied, and when as much intelligence shall be brought to bear in discriminating the good qualities of Rabbits as in the case of the feathered tribe, their owners will have to be very thankful. I trust this enviable state of things is not far distant.

I am glad to find so much interest excited on behalf of Rabbits, and am quite certain good must result from what we have seen and heard upon the subject during the last few weeks, and I feel confident that all committees for their own sakes will see the importance of appointing a competent judge for the Rabbits, irrespective of his knowledge of poultry or Pigeons, be that extensive or limited.

Some allusion at times is made to the points of excellence, and the peculiarities of different kinds. The "Lops" I am glad (as I am sure many others will be) have been ably described by Mr. Hudson, and I now venture to say a little in reference to the other varieties.

If I had to attach some distinctive words by way of appellation, to each variety, they would be as follow:—The Lop-eared I should designate graceful; the Patagonian and Belgian Hare Rabbit as majestic or noble; the Angora as showy; the Himalayan as neat; the Silver Grey as of a mercurial temperament; and the Dutch as pretty. Now, all these I keep and I have carefully noticed their peculiarities. About three hundred are born in my rabbitry every year. I shall refer to them alphabetically.

The Angora, originally from the town of that name in Asia Minor, is of a kindly disposition, and the doe very proud of her young. At times I think no sight can be more pleasing to a Rabbit-fancier than to see a pure white doe with her equally white and silky family around her. I do not quite incline to the belief that the buck of this variety is so fretful as represented when separated from the doe, neither do I feel quite sure as to the safety of the young ones just born, if the buck is left with them; not that he would destroy them in so savage a manner as bucks of other varieties, yet I think the chances are that many would be trampled to death. As the result of my experience, I recommend that the parents be separated until the young are at the least six weeks old, especially if you would have quality instead of quantity. There is not that distinctive feature as to the markings of colour as in some other varieties, the important point being length and silky quality of hair irrespective of the markings. White seems to be the favourite colour, yet it is not the point to insure a prize if the hair is not of the proper length and quality, and I have seen black and white, blue and white, grey and white all first-prize winners, possessing the other requisites—namely, length and silky quality of hair. The hair, on the Continent especially, is made of commercial importance, and I have met with both French and Germans who have done a rather large business in this commodity, and in which I am sorry to say the poor Rabbits have to be painfully interested by having the hair torn from their backs three or four times a-year. I would recommend the torturers of such innocent-looking pets to cease such cruelty, and to the attention of the Society for the Prevention of Cruelty to Animals. Perhaps the best method of removing the hair when matted, which is generally the case when many young ones run together, is by means of an iron comb (dressing comb), removing a little at a time, and in a few days the old fur will be gone, and the second will not again become so awkward to manage, especially if attended to every few weeks. Thus the Rabbits are always smooth and fit to exhibit, and the hair becomes longer with age, and may be used for a variety of purposes if the skin is properly cured.

The Belgian Hare variety is an excellent breed for table purposes, and may be reared to a large size. I have them weighing 10½ lbs. The marking is unlike that of the ordinary grey common Rabbit, as some darker shade of hair seems spread over the body, giving the animal a more rich and mottled appearance, and in general resembling the Hare. I find this breed rather delicate to rear, especially in very hot weather. The doe is prolific, eight or ten being the usual litters I have. These Rabbits are imported from the Continent, and more especially from Belgium. The doe seems rather more wild than with some other varieties, and easily frightened. I have known the new-born litters quite forsaken at the appearance of a mouse in the hutch, or on a loud peal of thunder being heard. Most of the other varieties are alarmed by the

same causes, but I think this variety more nervous than the rest.

The Patagonians I will now speak of as in some respects the same—that is, as being a large animal, yet not at all the same variety. They are at times spoken of as Flemish Giants, Ram Rabbits, &c. They attain from 15 lbs. to 18 lbs. weight, and are of two shades—grey, and the so-called cream shade. The ears are long, and not decidedly either lops or erect, but seem to hang loosely. The disposition of this Rabbit is kind, and I have often seen a small Dutch buck chase a Patagonian one round the enclosed court-yard and try to provoke the "giant," compared to itself, to fight. The does are not the most prolific, and I do not generally obtain from them more than three litters in a year. The Belgian Hare Rabbit doe and Patagonian buck produce some excellent specimens for the table, and when kept for this purpose I know of no Rabbits more profitable.

I shall, ere long, say a little about the Dutch, Himalayan, and Silver Greys.—Charles Rayson, *York Mount, Prestwich, near Manchester.*

THE HONEY HARVEST IN NORTHUMBERLAND.

This year has been somewhat peculiar with respect to bees in Northumberland. Swarming commenced in the end of May; such swarms going on rapidly threw off what we call virgin swarms, several top swarms throwing off two and three each. Here a virgin swarm is thought remarkable: hence, this season is considered an extraordinary one in this respect, and also for fly-away swarms and queens which could not fly at all, and yet we have not on the whole an average number of swarms. A sudden change in the weather at the beginning of June seemed to put a stop to swarming. Hence we have more than an average number of old stocks unswarmed, and many swarms too late to do well, yet the flower honey harvest has been good. Good supers have been taken off non-swarmers and early top swarms, and about an average number of hives were sent to the moors at the end of July and beginning of August. Two weeks of cold weather put an end to the weakest hives, and considerably lightened the whole; then for nine or ten days we had a grand bloom on the heather and weather unprecedentedly fine, but the time was too short, for the result is, that more than half the hives on the moors are lighter than when taken there, and ten per cent. of the bees dead. Those which have entered the supers have mostly only a few leaves of half-filled and unsealed comb, emblematical of good intentions being cut short by the rains which fell when the heather was in its prime. I have heard of a few supers weighing 20 lbs. and one 30 lbs., nicely sealed. These I set down for the hives which, being strong, filled their supers from the weak ones unable to defend their scanty store.—George Wilson, *Whalton.*

SPURIOUS HONEY.

I was glad to read in the number of October 14th the letter from Mr. A. Pettigrew, of Manchester, on "Spurious Honey." I am sorry to say that the practice of filling up honeycomb for sale and exhibition is very common, both in England and Scotland.

I have been a bee-keeper nearly twenty years, and I never could accomplish the massive weights of supers and bell-glasses that I see exhibited. The situation of my apiary is perhaps as good as any in Lancashire; it is on the borders of the river Tame, and there is no better land in the county. I know a person who exhibits honey, and who has taken several prizes with large bell-glasses weighing upwards of 40 lbs., and supposed to be gathered in a district which I consider one of the worst in the county, and he presumes to make people believe that bees can gather honey from land poisoned by the smoke of large towns, and amongst manufactures of the most filthy kind, such as chemical works, and where others to my knowledge have been compelled to remove their works owing to the intolerable stench. I say if bees can do well in a locality like that, they can do better than mine in a healthy neighbourhood. My bees this season have made up my nine bar-and-frame hives to about 30 lbs., and given me a bell-glass of from 5 to 10 lbs. each. I could not get more from them.

I am very glad Mr. Pettigrew is exposing the system of selling sugar and water instead of honey. I have often doubted the purity of large glasses, but I should be very sorry to charge anyone with so dishonest an action. I should like the committees of our poultry shows to offer prizes for bees and honey; their doing so would be the means of encouraging bee-keeping, which would be a profit to the working man at a very little outlay. Consider the tons of honey lost upon the heather from the want of bees being taken to it to gather the pollen. I know several working men who by their bees and honey make the rent of their house and something to spare. At the Middleton Show this year there were nine entries of bees and honey, and this department of the exhibition was an attraction to many. The first year I was judge of bees there, we had only two entries, but the number has increased year by year. The first prize this year was £3 for the best collection of bees in the hive, and £1 for the best collection of honey.—South Lancashire Bee-keeper.

REGICIDE.

I wish to ask my brother apiarians if they have ever met with a similar misfortune to that which has just befallen me.

Being about to join two hives of bees and wishing to select the best queen of the two, I proceeded to find them. Having secured No. 1, I placed her with a few workers in a small box. I then found No. 2, and as I was taking her off the comb I dropped her into the hive; the bees immediately set upon and killed her. I then, after an absence of only five minutes, placed No. 1 on the alighting-board of her own hive; she was also seized upon, and although I at once got her away from her disgraceful people, she also died in about ten minutes.

The supposition might be, that I had changed queens, but this I am quite positive I did not do, as queen No. 2 was just over her own hive when I dropped her into it, and, of course, had not left them half a minute. Can anyone account for this? Only a day or two back I introduced a Ligurian, kindly sent to me by a friend, and she was at once accepted without the slightest manifestation of resentment. Of course, after this experience I shall never attempt to return a queen until after a few hours' absence.—T. B. H.

[We should fancy that in both these cases the regicidal attacks were initiated by robber bees, which at this season seem to be constantly on the alert for plunder the moment a hive is opened, or an operation attempted. It is certainly very unusual for bees to attack their queen after a brief absence. The only similar instance which we remember to have seen recorded, was related by Mr. Woodbury, in page 366 of the third volume of our new series.]

QUEEN CELLS IN AUTUMN.

I drove two stocks of bees a fortnight ago and put them together, taking the best of the combs, and fixing the others in a frame hive. I have since been feeding them to make up weight, and the other day took off the fastenings from the combs, when to my surprise I found on one of them five queen cells with young queens in all, but no brood in any other comb. Is it not unusual at this time of the year?—M. A.

[The construction of royal cells at this season shows that both queens were killed in uniting the bees. As no young queen can now be impregnated owing to the want of drones, the survivor must be removed and a fertile queen substituted, or the stock will inevitably come to grief.]

NEW PUBLICATION.

The Animal World: A Monthly Advocate of Humanity. No. 1. Oct. 1, 1869. Price Twopence.

We welcome most heartily the above new publication. It is just to our taste, and likely to promote kindness to animals, and prevent cruelty. "The Animal World" is published by the Royal Society for the Prevention of Cruelty to Animals, a Society which since its foundation in 1824 has done an infinite deal of good by the prosecution of persons guilty of flagrant acts of cruelty, and also has prevented much evil by the fact of its existence being known, for it has been a terror to the evildoer. The costermongers, the donkey-keepers, the goat-drivers, have been taught that they cannot treat cruelly their animals with impunity. But it is not enough to punish the cruel, it is necessary to train the young to kindness. A child will tear off the wings of a fly; a boy, or girl alas! as we have known, will torture young birds; and thoroughly bad boys will ceaselessly pelt with stones poor stray dogs. Then there

is a cruelty which is not thought to be cruel, the cruelty of carelessness; as Thomas Hood truly said—

"Evil is wrought by want of thought,
As well as by want of heart."

Now, to train for good and check cruelty comes this excellent serial, which, from its size, that of the *Pall Mall Gazette*, its letterpress, and, above all, its excellent pictures and low price, will we are sure, if future numbers be equal to the first, be certain to obtain a wide circulation. The October number contains an article, illustrated, on the horse; one on monkeys, by Frank Buckland; a serial story of "The dog which found a lost child," by Mary Howitt. We have poetry as well as prose, practical articles as well as narratives, cautions against cruelty, exposure of the cruelty of the bearing-rein—in short, we have sixteen pages of useful, pleasing, and instructive matter. The Bishop of Gloucester and Bristol, who took great pains to get three humane clauses added to the Contagious Diseases (Animals) Act, contributes an excellent letter on the humane education of children.

To this first number of "The Animal World" is attached a supplement, giving a short history of the Society for the Prevention of Cruelty to Animals, and a full report of its forty-fifth annual meeting. The report and speeches will well repay perusal.

We earnestly recommend heads of families to take in "The Animal World," and be sure and let it find its way into the kitchen. Clergymen could not do better than take a monthly bundle of six (only 1s.), for their schools; first for the children, and then to be spelled through by the ploughboys and others by the winter fireside. Seriously and thoughtfully do we say, God speed the course of "The Animal World," and may its motto, from Coleridge's "Ancient Mariner," find an echo in its readers' hearts.

"He prayeth well who loveth well
Both man, and bird, and beast;
He prayeth best who loveth best
All things both great and small;
For the dear God who loveth us,
He made and loveth all."

—Wiltshire Rector.

OUR LETTER BOX.

Middleton Show (*C. Sidgwick*).—Messrs. Mason & Walker wrote to inform us that the prize was awarded, and had been paid to them.

Malt for Fowls (*H. B.*).—Malt would be too stimulating if it were given as regular food. Fowls are very fond of it, and will eat it to excess. It has the property of making the eggs taste of it, also the flesh if the fowl be killed while it remains the daily food.

Breeding from a Cockerel (*Idem*).—If the bird is desirable in other respects, his age is not the slightest objection, provided he is not less than nine months old.

Breeding from Sitters and Non-sitters (*Idem*).—It is desirable to rear poultry, although intended for table purposes only, at the least cost and with the least trouble. For this reason we always oppose the mixture of sitters and non-sitters. They are capricious sitters when they are thus bred, and many an amateur knows the vexation of being told a day or two before the chickens should be hatched, that the hen has been off her eggs all day. We cannot imagine what fowls you would like to cross, unless it were Brahmas and some of the French breeds. We would rather have the former pure, and if we wanted some other sort we would put a few French eggs under a Brahma hen, and eat the two breeds pure. We are not friendly to crosses, and have seldom seen much good done by them.

Dari Corn (*G. B.*).—We do not know the Dari corn. Some of the Indian grass seeds are called Doora. Indian corn makes birds very fat. You have been correctly informed, it makes them very fat internally, enough so to impede the action of the intestines. It makes, to use the verdict of a very learned man, neither "osmazome nor fibrine." It makes little lean, and that which it makes is dry, hard, and black. We do not admire any of these expedients for cheap feeding. We find that which costs little money yields little nourishment. We will feed our birds on good oat and barley meal, and will allow anyone to try the new discoveries—rice, damaged raisins, different foreign corns, biscuit, all the various pastes, with the conviction we shall not only have the best condition, but that ours will be the least expensive.

Feeding Brahma Pootras (*T. S. J.*).—We said "eschew potatoes" because our experience was unfavourable; they have a tendency to produce internal fat, and they almost always produce the luxury called a fat liver. When this goes on, adieu to all condition and health. The fat increases, but the weight diminishes; the skin becomes hard, brown, and dry. All the nourishment is absorbed by the liver, which increases daily, until it is almost the most valuable part of the fowl. We disapprove altogether of your mode of feeding. We should do away with the wheat and oats; we will allow you to give two meals of potatoes every week. Substitute barley or oatmeal for the potatoes and sharps. Do away immediately with your trough; you will never make heavy birds if you allow them a trough. Feed by hand, and throw the food broadcast. If they come close to you, drop some choice pieces for them. Add to the dietary we have given above some cooked meat chopped fine; in very wet or damp weather give a little ale.

Fowl's Legs Scaly and Warted (*Idem*).—It is impossible any birds can be healthy, kept on a wooden floor, and the legs and feet are the first parts affected. In a state of nature a fowl, like a Pheasant, Grouse, or Partridge, walking on the earth clasps each step by driving the claws into the earth; the foot sinks into it at the same time. If the bird wants to scratch, there is nothing to hinder. It finds food and amusement; it meets with all that is necessary for health. On a board the foot is always kept stretched out. The ends of the nails cannot penetrate the boards, the foot is kept in an unnatural position, and lameness is the result. Apply salad oil freely to the spots on the legs, then rub the places affected with compound sulphur ointment. Feed on oat and barley meal. Give up wheat and oats. Let them have a little cooked meat chopped fine, and, above all, if they are to remain where they are now, cover the boards with at least 6 inches of gravel and road sand. Give them some sods of growing grass. It is utterly impossible to have fowls healthy if they are kept on clean boards.

Fowls not Laying (*M., Chichester*).—Hens will not regularly lay in the winter; only pullets can be depended upon to do so. You should therefore keep some early pullets every year to provide you with eggs in the winter. As a rule fowls do not like oats, and we expect they do better on what they pick up than they do on your hand-feeding. That which is worth doing at all is worth doing well, and to get eggs in the winter is to do fowls well. You must feed differently. Have your oats ground fine—so fine that the meal will make dough like flour. You must take nothing from it, but grind husk and all. Give them some whole barley for a change, and once a week a few boiled potatoes. If you will feed in this way, and keep some April and May pullets every year, you will have eggs all through the winter. We look with suspicion when you say they roost in a loft, and are closely packed in a room 12 or 14 feet square. There is not room enough. There is the bad wooden flooring, the difficulty of access and egress. They should roost on the ground floor, and the more room they have the better.

Sale of Poultry (*Idem*).—With regard to the sale of poultry, we have always considered our own columns as the best medium, and we believe if they were more used for that purpose amateurs would find sales promoted by it. There are generally buyers for good birds at fair prices if publicity is given to the fact they are to be had. How often do we hear from a neighbour, "I wish I had known you had such things for sale. I have been seeking them a long time, and only bought them last week."

Dorking Cockerel Declining (*P. D'Anson*).—We fear he has some of his viscera ulcerated, in which case no treatment could save him. If he is only weak, bread soaked in ale given twice a-day, and a dessert-spoonful of cod-liver oil once daily, may restore him.

Turkeys' Legs Failing (*C. R.*).—Neither gout nor rheumatism is affecting their legs, but either painful weakness or cold contracted from a very damp or ill-fitted roosting house. A roosting house with a very damp clayey floor will cause it, or a brick, stone, or wooden floor. These are the most fruitful causes of swollen knees. Bad and irregular feeding will cause weakness, and Turkeys are very subject to large knee-joints. It seems their place of weakness, to which all mischief runs. Give them freely bread steeped in ale, and administer some camphor, two pills the size of a pea. Put some camphor in their water.

Tumblers not Flying (*E. S. Polkinghorne*).—As the plan we advised you to adopt does not seem to answer permanently, there is nothing left but to drive your Tumblers up by pelting at them, say pieces of mould or turf, or any substance which would not injure them or break windows; at the same time not letting them grow fat by over-feeding. As your house is awkward for flying Tumblers, why not try the higher class, the Shortfaces? You would find that beauty of form and feather would amply compensate for tumbling, and you could keep them confined. Or Antwerps would suit you. Remember, that only after being long shut in will any Tumblers take extraordinary flights, and these have been magnified both by word of mouth and in books.

Summer Rape for Seed (*Marian*).—Seed called summer rape is grown in Germany. It is little used in this country, and the most likely place to procure it is at Mr. Hawkins's, dealer in birds, Bear Street, Leicester Square. You would find English rape and Canary seed, with chickweed and plaintain occasionally, the best food for a Linnet.

Canaries Consumptive (*M. Y.*).—"The symptoms—panting, becoming thin, and losing colour, are those of rapid consumption, a disease to which the Canary is only too liable. It is incurable, and though its miseries may in some cases be alleviated, it eventually claims its victim. It is so certain in its attack, that no man of any experience would buy a bird with any 'pant,' knowing full well that the breeding season or succeeding moulting time would end its days. I have before expressed my opinion, that the great cause of disease in Canaries is a disordered stomach, and many ailments eventuating in a sickness, the prominent features of which are, 'the birds ruffle their feathers, put their heads under their wings, pant, are reduced to skeletons, and become discoloured,' might be averted by a timely dose of castor oil. I believe that really very little is known about the diseases of birds. I am quite open to confess that I am a poor bird-doctor, but my castor-oil bottle is the chief feature of my medicine chest, and I lose as few as my neighbours. —W. A. Blakston."

What are the Advantages of Ligurian Bees? (*G. B.*).—"Good temper, beauty, and fecundity.—Devonshire Bee-keeper."

POULTRY MARKET.—October 20.

A moderate supply and a somewhat improved trade have improved the aspect of our market. Should the present change in the weather continue we may look for better prices.

From observations taken near London during the last forty-two years, the average day temperature of the week is 54 2°; and its night temperature 37 3°. The greatest heat was 67°, on the 31st, 1854; and the lowest cold 22°, on the 28th, 1836; and 1st, 1866. The greatest fall of rain was 1.03 inch.

DECORATIONS OF AUTUMNAL LEAVES.

"'Tis but a whim—but oh! entwine
These leaves around that brow of thine.'

SO said my cousin Nelly—and I did so entwine them, and that wreath of mingled Fern and Virginian Creeper leaves was more admired—deservedly admired—than any other head-gear that night. Why are not autumnal-tinted leaves more used for purposes of personal, and room, and table-ornamentation? They can be rendered long-enduring, and

'These leaves are tinged with beauty far above
Spring's gayest hues, or brightest, freshest green:
Their blending shades of every tint are seen;
Pale amber, half transparent in the ray
Of the bright sun; brown, red, grey,
Varied in hue and form, bestrew the way.'

"Now, I dare say that you dry old Editors will pooh-pooh this, and feel disposed to put all into your Balaam-basket, and designate it 'the romantic stuff of a school girl;' but I do ask you not to pooh-pooh it, and as I am nearer to twice 'sweet seventeen' than there is any necessity to be told, it is not 'school girls'' sentimentalism, and many would be pleased with information on the subject besides—Myself.

"P.S.—I want such information as will enable me to select leaves—to be told what is their colour in autumn, and how to fasten them."

[Now, is not that truly a woman's letter? The sole object for which it was written is in the postscript, and she ventures to pen-buffet those from whom she asks aid. How near to being "old Editors" we are we do not recognise that "there is any necessity to be told," and as evidence that we are not "dry" even on autumn leaves, we add the following from an American contemporary:—

"Foreigners are deeply impressed with the autumnal splendour of our American forests. This gorgeous colouring of the ripened foliage, which is much more brilliant with us than in other countries, sets the deciduous trees in vivid contrast with the sombre-hued Firs and Pines, and makes of the most ordinary landscape a charming picture. A portion of this splendour, which in autumn is lavishly scattered abroad, we may rescue awhile from decay, and, brightening with it our in-door life, fill the dark days of winter with light and beauty.

"Since an observant American woman has taught the Parisian belles how becoming our autumn leaves are to dark-haired ladies, and thus created a demand for this foliage as a personal decoration, its wonderfully-varied tintings have been more generally noticed and admired; and many attempts are made to retain this beauty, which, when properly preserved and managed, gives elegance to the humblest apartment.

"Though a few trees may ripen their leaves in August, it is not till the middle or last of September that we can obtain them in variety; while even as late as November we must wait for some species. Then, whether we pick them from the ground, or cut twigs and branches from the trees, only the most perfect in form, and the clearest in their hues, and the most nicely shaded should be selected, being careful that each leaf has its stem uninjured.

"As soon as possible after gathering them the leaves must be pressed. If they begin to welt or shrivel before you are ready to press them, put them in water, and keep them there till they revive. See that no soil, no foreign substance of any kind, is on either side, and then with a warm, not hot, flat iron press and iron each leaf on its upper surface till it is perfectly dry; spreading it for this purpose on several layers of paper, or on an ordinary ironing-board, just as if it were cotton cloth. This over, oil each leaf on the same side on which it was ironed with linseed, olive, or lard oil, using a small camel-hair brush, or a bit of cotton batting tied to a stick, and then place them on dishes in the sunshine to dry. When dry, reject all those that have a semi-transparent or oily appearance; to prevent this, get the thickest leaves you can for your collection, and do not oil them too generously nor with a rough brush.

"If you wish to arrange the leaves in boughs, or sprays, or long garlands, procure a few knots of brown worsted, and a quantity of fine wire; old bonnet-wire cleared of its covering, or the wire from the heading of old brooms, is of the right size, and very convenient to use. When the oiled leaves are dry, assort the different kinds according to their species—that is, place the Rock or Sugar Maples together, then the Red or Swamp Maples, the English Elms, the American Elms, the White Oak, the Black Oak, and so on; because, though several species are allowable in a garland, it would be unnatural to mingle them in sprays or boughs. The only proper way, however, of bringing them together is to bind the various sprays into a large bouquet; thus the contrasting forms and hues have a good effect.

"Cut the wire into pieces of different lengths. You will need a great many 3 and 4 inches long, several a foot long, and a few 2 feet or more, according to the length of the branch or the garland you wish to make. Take the smallest leaves for the tips of the sprays and branches, and follow these with others of larger size, proceeding regularly till you have the largest leaves at the base of the branch; keeping an eye, at the same time, to the agreeable union of varying shades, and studying the marking and blotching of each leaf, so that it shall have no glaring contrast in its nearest fellows; and thus, with the greatest variety in the group, the whole are blended harmoniously and pleasantly.

"Begin your work by attaching all but the very smallest leaves to the short wires, placing the wire beneath the stem, and in such a manner that it strengthens its whole length; and then wind the worsted around both so closely and tightly that nothing of the stem or wire can be seen. Then take a small leaf and fasten it in the same way to a long wire, which is to be the main stalk of a branch. Along this dispose the other leaves naturally; bending the ends of their wires as needed, and covering all together by continuing to wind the worsted as before. Several branchlets or sprays may thus be gathered on one stalk, forming a large bough or a long garland. Avoid stiffness and flat-

ness of position; set and bend the stems in a life-like manner. For this the wire stems are a great advantage. They also contribute to the durability of the leaves, which, if preserved with no support save their own stems, are soon broken unless extreme care is taken.

"The beauty of Oak leaves is much enhanced if clusters of acorns in their cups are introduced among them. The cups must be punctured with an awl, to admit the end of the wire that is to serve as a stem, and the acorns then glued to the inside of the cups. When these are dry, wind the wire with the brown worsted as in uniting the leaves. Birch burrs must be glued directly to the wire, which it will be convenient to wind with the worsted, and form into a branch before the glueing takes place. They are a pretty addition to branches of the golden Birch leaves. The red berries of the Black Alder, and the scarlet and orange seed vessels of the Celastrus scandens (Climbing Bitter-sweet), gathered before the frost has touched them, will keep fresh and bright on their own stems a long time, and add much to the beauty of any collection of leaves.

"These boughs and garlands, arranged tastefully in vases, drooping around pictures or statuary, or hanging upon the walls of a room, seem to lend it the sunshine of a perpetual Indian summer. The most desirable leaves for this purpose are those of the Oak, Maple, Elm, Sumach, Birch, and wild Cherry; though contributions from woody shrubs and garden bushes never come amiss, if of substantial texture and smooth surface; and green leaves of Fern—fronds of the common Brake—with their long plumes of verdure, make an agreeable contrast to more brilliant colours and more fanciful shapes. Fern leaves should be ironed in the same manner as other foliage; but they need no oiling, and if not hung where the air is intensely hot and dry, will remain handsome several months.

"It is a mistaken notion that autumn leaves need varnishing. Varnish makes them brittle, and more liable to crack; while the excessive lustre that it imparts is unnatural. Oiling gives sufficient polish, deepens, clears, and preserves the colours, and keeps the tissues somewhat elastic. When the leaves get dusty, wipe them with a damp cloth. If they curl, damp them, and place the branch for a few hours between papers under a pile of heavy books.

"The changed leaves of autumn may also be used for other ornamental purposes. Small wreaths to surround unframed pictures can be made, fastening the wired stems by sewing, or by winding with worsted, to a narrow circle of pasteboard, or a ring of wire-taste; the Sumach, Elm, or Cherry leaves are best for these. And carving may be successfully imitated with Oak leaves and acorns. For this, glue the under surface of the leaves to a picture-frame of pasteboard, or of wood stained a dark colour; cut the acorns, and their cups also, in halves, and intersperse them among the leaves, glueing them in a flat position, and then varnish the whole. The same work makes a pretty front for a bracket. And little sprigs and branches of Maple, Elm, or Cherry, with their natural stems, may be ironed, and then fastened with gum tragacanth to the pretty white-wooded boxes, letter-cases, and other articles that are prepared for painting and decalcomanie; being afterwards lightly varnished, or not at all, according to fancy. Sprays of Maple or Elm, or Oak leaves and acorns, may, in the same way, ornament pasteboard or wooden slips for letter and card racks; the lining, which should be of the same shade as the leaves, being first glued to the frame.—Annie G. Hale."]

ROSES—MANETTI STOCKS—STANDARDS—NEW VARIETIES.

Although many of your readers will, perhaps, be getting tired of hearing so many different experiences in the matter of Roses, yet, as I believe there are more persons interested about Roses and Pelargoniums than about any other flowers, I will risk the chance of being tedious, and add my own observations to those which have already been called forth in your Journal by my friend "D.," late of Deal.

I will begin by saying a few words about the Manetti stock, as I have now had an experience of seventeen years with it, and have, therefore, some knowledge of its value. In the first place I am far from agreeing with those who say the Briar is doomed; because upon all strong lands the Briar is a far better stock than the Manetti, but the especial value of the Manetti is that it will suit soil where the Briar will not thrive. Light loam, sandy soils, and soils with too much peat—all can be made with proper care and attention to grow good Roses on the Manetti stock, while on the Briar these would only have a struggle for existence. Another great advantage is, that as the union of the stock and scion in the Manetti ought to be planted at least from 2 to 3 inches below the surface of the ground, it affords a great protection against frost. In the winter of 1860 I had only two standards left alive out of sixty, whereas, though all the plants I had on the Manetti, except very few, were cut to the ground, they all sprung up again and bloomed fairly the very next season.

Another advantage is, that in nine cases out of ten Roses on the Manetti stock push out roots of their own above the union, more especially the stronger kinds, such as Madame Clémence Joigneaux, Charles Lefebvre, John Hopper, Gloire de Dijon, &c. I have removed in the autumn plants only planted the previous spring, and the roots from the Rose were nearly as strong as those of the Manetti stock. I have my prejudices, too, against standards. I mean tall standards; dwarfs may be admissible, but I think a tall standard is quite the ugliest form in which a Rose can be grown, is liable to every breath of wind, and cannot be protected against King Frost. No doubt there are a certain number of positions, as the centre of a large Rose bed, where tall standards may be made use of, but I have never yet been able to admire long lines of tall single standards by the sides of walks, tied to stakes far larger than the stem of the Briar itself, and only looking well during the short period of their blooming.

Still, in strong soils, especially clay, with stiff subsoils, the Manetti stock is of no use, and there the Briar will thrive, and what is more to the point, produce finer-coloured Roses than any light soil will, however well the Roses on the Manetti stock are manured. But I look upon it that the Manetti has done more to popularise the Rose than the Briar, because it enables amateurs by means of the two stocks, whatever may be the character of their soil, to grow Roses with advantage, and it has enabled nurserymen to increase the stock of new Roses much more rapidly by grafting in heat in the spring; and a much greater number of good buds may be obtained in the same space of time from the Manetti than the Dog Rose.

I have heard some objections made to the Manetti on the score of suckers; but this is always due to bad management. In the first place, it never sends out root suckers like the Dog Rose; secondly, if the stock is planted deep enough, the eyes below the bud do not push; and thirdly, all eyes ought to be taken out of the stock before planting. As a proof how little troublesome the shoots of the Manetti are, out of a new quarter of 250 Roses, planted in the spring of this year, I only had two Manetti shoots; whereas from six dwarf standards in one of the beds, planted in the middle of some Roses on the Manetti stock, I had to remove two or three suckers from each stock in the course of the summer.

Some persons, too, have thought that because the Dog Rose is a native of Great Britain, and to be seen wild in nearly every hedge, that it must be hardier than the Manetti; but in the winter of 1860 I had the Dog Rose stocks themselves killed, whereas some large old plants of Manetti that were allowed to grow wild, in order to take cuttings from them, were hardly injured at all; and in the hedgerows about here all the old wood of the Briars was killed, and only the younger and stronger plants survived.

Having said so much about the Manetti, I will curtail my remarks on the Roses, but wish to ask, before leaving the subject of stocks, why more trial has not been given to the Céline stock, which is a very free and surface-rooting kind, a strong grower, and suits the dwarfer kinds of Bourbons better than the Manetti? I should like such kinds as Madame Vidot, Madame Furtado, and Louis XIV. to have a good trial on this stock, as I think it would much increase their strength and vigour.

Now, as regards well-known and well-established kinds, as John Hopper, Charles Lefebvre, Senateur Vaisse, &c., I can only say ditto to Mr. Burke with regard to what has been said about them. Madame Vidot and Comtesse de Chabrillant have done exceptionally well with me this year. Madame Furtado still fails to grow, and though I think it one of the most beautiful Roses grown, I am every year more out of heart with it.

We have had a great accession of strength in pink Roses lately—Marguerite de St. Amand, Princesse Marie de Cambridge, Abel Grand, Monsieur Noman, Elie Morel, and Baronne de Rothschild. The two most perfect blooms of Roses that I think I have seen this year, were both Baronne de Rothschild, which I saw when helping to judge the nurserymen's classes

at the Crystal Palace and Kensington Rose Shows, in both cases exhibited by Mr. Cant, and I think it will be a favourite Rose for many years to come; it opens its blooms well, and seems to have sufficient substance of petal to stand the sun, and the colour the most beautiful smooth satiny pink. Monsieur Noman is also a grand Rose. I myself thought there were very few good new Roses shown either at the Crystal Palace or Kensington, with the exception of Elie Morel, La France, Duke of Edinburgh, which has been good everywhere, Reine du Midi, and Pitord; but Clémence Raoux, Edward Morren, Henry Ledechaux, Julia Trouvais, Julia Treyve, Madame Creyton, Thyra Hammerick, which I believe are the best of this year's Roses, were not exhibited. I am afraid I shall have to join in the verdict which places Paul Verdier among the summer Roses only; but it is so fine a Rose with me, that I shall not give it up on that account. Alfred Colomb is, in my opinion, a better Rose than Marie Baumann, as the latter is too weak in the stem and hangs its head; it is at present a good race for the premiership between Charles Lefebvre and Alfred Colomb, but though the latter may be the finer-shaped Rose for exhibition purposes, yet the former is the more useful for the garden. After all, when in perfection, no Rose equals Maréchal Niel, and though we are told that Gloire de Dijon is the proper stock for it, yet I have seen it on the wall of my father-in-law's house in this parish, budded on the Manetti stock, make a shoot this year more than 13 feet long, and it had from twenty-five to thirty fine blooms the second year after planting, with some of the largest leaves I ever saw on a Rose; in fact, I never saw a plant in greater health and vigour.

Time and space warn me that I must bring these remarks to an end, and I will conclude by giving a list of those Roses, according to their colours, which have proved most valuable to me.

White.—Baronne de Maynard, Mdlle. Bonnaire, and Virginal, to which I add Souvenir de Malmaison, for though not pure white, yet it is one of the most useful and beautiful Roses when properly managed, but it requires a shady place, and must not be exposed to the full blaze of a midday sun, for this is the reason it often does not open well in the summer, and gives better blooms in the autumn. Acidalie is also another of the same class.

Pink.—To the six I have already named I add Cécile de Chabrillant, still one of the best and finest-shaped Roses grown, Alphonse Karr, and La France.

Rose-coloured.—Madame Furtado, difficult to grow; Madame Hector Jacquin, though not full enough, still a beautiful Rose; Madame Knorr, and Duchesse de Morny, one of the very finest Roses grown.

Cerise.—Madame C. Crapelet, John Hopper, Victor Verdier, Thorin, Madame Boutin.

Scarlet and Crimson Scarlets.—Le Rhone, La Brillante, Horace Vernet, Alfred Colomb, Marie Baumann, François Lacharme, Senateur Vaisse, Madame Victor Verdier, Fisher Holmes, and Duke of Edinburgh.

Crimson.—Charles Lefebvre, Lady Suffield, Mdlle. Marie Rady, François Louvat, Black Prince.

Dark Crimson.—Duke of Wellington, Lord Macaulay, Pierre Notting, Monsieur Boncenne, Xavier Olibo, Vicomte Vigier. Nearly all dark Roses ought not to be exposed to the midday sun.

There are some very good Roses, such as Madame Clémence Joigneaux, Antoine Ducher, Madame Caillat, and a few others, whose colour it is difficult to classify. The Roses that have disappointed me more than others this summer have been Charles Rouillard, Alpaïde de Rotalier, Hippolyte Flandrin, Exposition de Brie, and Duc de Rohan, all of which are fine-weather Roses.

There is one class of Roses especial favourites of mine, which, in my opinion, are not sufficiently grown, because they are not quite large enough for exhibition Roses, but which are the most constant second bloomers, and are most of them beautifully shaped; I allude to the Hybrid Bourbons, as Louise Odier, Louise Margottin, Modèle de Perfection, Emotion, Catherine Guillot, Baronne de Noirmont, Baron Gonella, and Michel Bonnet. These are more decidedly Perpetuals than any, except the Noisette and Tea Roses, neither of which I have hitherto alluded to, as there are so very few that are of general use, Gloire de Dijon and Céline Forestier being glorious exceptions.

I cannot conclude these remarks on the Rose without adding that I strongly recommend all the lovers of the Rose to obtain the Rev. S. R. Hole's new work on the Rose, which contains both a fund of information and amusement, and will, I am sure, prove interesting to every rosarian.—C. P. Peach, *Appleton-le-Street, Malton.*

CLERODENDRON FALLAX FROM SEED.

When well grown there is much to admire in this plant. Its noble spikes of scarlet flowers rising above its broad dark green foliage, and its easy culture, are qualities which entitle it to more extensive cultivation than at present. It is, however, not often that the dimensions of the stove will allow of more than a specimen or two being grown in order to complete a good collection of stove plants, and such is the case at this place; I therefore determined to try to grow it in an intermediate temperature for conservatory decoration. With this object in view I raised a number of plants from seed, and grew them for blooming in September and October. I believe I have perfectly succeeded, because now and for a month past a length of about 20 yards in the front part of the conservatory is decorated with the gorgeous flowers of this Clerodendron, which have a very pleasing effect when mixed with other flowers, and with foliage of a contrasting character, especially when viewed from either end. I now consider myself well repaid for the trouble I have taken, and shall raise some plants again another year; but I should also like others to grow some for the same purpose, therefore I will give a detailed account of the mode of treatment which I pursued.

The seeds were gathered from an old plant in the autumn, and in the first week of the succeeding March they were sown in a pan, and placed in a heat of 60°. The soil used was finely sifted sandy peat. When the seedlings came up (and they were not long in doing so), they were almost immediately large enough to occupy 2-inch pots, and in potting them, the same kind of soil was used, with the addition of a few handfuls of silver sand. They were kept in the same place until they were large enough to be shifted into 4-inch pots. When the plants were again established they were removed to a more airy place with plenty of light, and shaded from the midday sun, but kept close to the glass. They had a temperature of 55°, with air admitted both at the back and front of the house, air being occasionally admitted all night, according to the weather. They remained in this position up to the opening of the first flower, but they were shifted into larger pots as they required, until they were in 8 and 10-inch pots, according to size; these were their blooming pots. At the last two pottings a third of turfy loam was added to the compost, and one-fourth well decomposed cow manure finely sifted, also a few handfuls of charcoal broken fine. This mixture of soil will be found to improve the colour of the foliage, and increase the size of the individual flowers. Water the plants plentifully at the root when required, but avoid syringing the foliage in the early part of the day, or even at any time, as a good moist atmosphere will be sufficient for the plants in the comparatively low temperature in which they are growing.

The principal insect enemies are red spider and green fly. The attacks of the former will be best guarded against by moisture in the atmosphere, and never allowing the roots and foliage of the young plants to become dry. For green fly the usual means of destruction by fumigation will answer; this should be particularly attended to just before the first flower opens, because if a few of these insects pass unobserved, by the time the flowers expand there will be multitudes of them, and fumigating then will bring off all the flowers which are open.

It is agreeably surprising to notice how deceptive are the heads of bloom, for what at the first appearance of the buds seems to be a diminutive head of bloom becomes developed into a spike of large proportions and great beauty. When raised from seed, the plants do not exceed 2 feet in height, and have just enough of foliage to set off the flowers to the greatest advantage.—Thomas Record, *Hawkhurst.*

GOLDEN CHAMPION GRAPE.

I have heard many complaints of this Vine being a bad grower. Some canes planted last winter have made scarcely any growth, and seem to all appearance scarcely worth keeping. I do not think this is entirely owing to its being a weak-growing variety, as I have two Vines which were planted last winter, and they have grown vigorously. May it not be in some instances the consequence of propagating from unripe wood, to which some may have had recourse in order to meet the excessive demand? Where the growth is very poor I would

recommend cutting the Vines well back in winter and laying the stems down to the roots, to make, if possible, a shoot start from below the ground level, and afterwards to fill the hollow with light compost; roots will issue from the base of the new shoot, and a vigorous growth will be the result. Another way would be to graft on a stronger-growing variety.

Mrs. Pince, contrary to the experience of "R. M. W.," and others, grows vigorously on its own roots here; it is, in fact, the most rampant grower I have seen.—J. W., *Oxton, Cheshire.*

HYACINTHS, TULIPS, AND OTHER BULBS IN POTS.

I am well aware that the subject of the cultivation of the Hyacinth in pots is almost a threadbare one; it has been frequently handled, and yet there are always found among the readers of The Journal of Horticulture a class who are in the infancy of their gardening profession, and who are glad of any information that comes within their reach.

Next in degree of enjoyment to that derived from the cultivation of the Hyacinth in glasses, is that of their culture in pots. To judge from the specimens one too frequently meets with, there is urgent necessity always for some directions on this head with the view of attaining a higher level of cultural skill. Use 6-inch pots for the purpose, and be content with one bulb in each. Use for potting a compost of one-half of hearty fibrous loam, and the other half of equal proportions of thoroughly well-rotted dung dry enough to be readily pulverised, and leaf soil. In selecting bulbs, do not always suppose the largest give the best spikes. Varieties of Hyacinths whose bulbs are generally very large—such as Waterloo, double red; and Lord Wellington, and Temple Van Apollo, single red, invariably throw two or three spikes, which are frequently small in size, instead of giving one large and bold illustration. I like Mr. James Cutbush's test of weight rather than mere size; this is a golden rule to be observed in the selection of Hyacinths. Pot about the end of October, or early in November, and if you like make two or three pottings of the Hyacinths with a view of aiding a succession of bloom, though it by no means follows that the Hyacinths last potted will be the best to bloom. Have a good large hole in the bottom of the pot, be sparing of drainage, and put something good next the crocks for the roots to lay hold of, as they are sure to go downwards. Do not press the soil hard on which the base of the bulb is to rest—some people pound it as if they were manufacturing a pavement—and cover fully two-thirds of the Hyacinth with soil. Where there is a cool, dry, dark cellar to place them in, you are independent of the traditional coal ashes. Where there is no such convenience, set your pots out of doors in some dry place, placing them on coal ashes or pieces of slate to keep the worms from making their way into the pots, and if you have them invert a thumb-pot over each bulb before covering them with coal ashes. This is intended simply to prevent any injury to the growing shoot by contact with the wet ashes. In six weeks or so, they will be fit to be disinterred, and can be placed in a cool greenhouse or frame, and allowed to take their own way.

Unless you are familiar with plant-forcing, and have the convenience for it, do not attempt it, and accept this hint as well worthy attention—whether you exhibit or no, endeavour to grow your Hyacinths as fine as possible. I once created a sensation at a Hyacinth exhibition in the midland districts by producing some flowers that were regarded as astonishingly fine for that district. I had a two-light frame at my disposal, and over the bottom of it I placed about 3 inches of rotten manure thoroughly saturated with a vigour-giving ammoniacal liquid. I then knocked away nearly the whole of the bottoms of the pots and placed them on the manure, and as soon as the slightest appearance of colour was presented, I applied once a-day some liquid manure made from green cow dung and diluted by one part to two parts of soft water. That floricultural "dodge," though I can hardly think it was unjustifiable, gained me both the first and second prizes in two classes, and overwhelmed my adversaries with envy and surprise.

The following are excellent sorts and by no means generally expensive varieties—viz., *Double Red:* Lord Wellington, a variety that should never be omitted. *Double Blue:* Laurens Koster and Bloksberg. *Double White:* La Tour d'Auvergne and Prince of Waterloo, but the last two are by no means essential. *Single Red:* Annie Isle, Duchess of Richmond, Emmeline, Gigantea, La Dame du Lac, Lord Wellington, Norma, Robert Steiger, Sultan's Favourite, and Temple of Apollo. *Single Blue.* Baron Van Tuyll, Bleu Mourant, Charles Dickens, Grand Lilas, Leonidas, Mimosa, Orondates, and Regulus. *Single White:* Alba Superbissima, Anna Paulowna, a fine single form of the old double Grootvoorst; Cleopatra, Grandeur à Merveille, Grand Vainqueur, Madame Van der Hoop, Mont Blanc, Seraphine, and Themistocles. *Single Yellow:* Anna Carolina and Heroine.

These give some thirty-four varieties, from which a good twenty-four could be selected.

At the London and Liverpool Hyacinth Shows, the pot is dropped into a larger one, and moss is nicely laid over the top. I imagine this to be a practice coming within the range of what Mr. William Paul terms (and condemns) as "floricultural millinery;" but then, as he does it himself, he at least would hesitate to include it.

In growing Hyacinths for exhibition, look well after the foliage. There is as much art in developing good foliage as in producing good flowers; and all other things considered, a thorough judge of Hyacinths attaches some importance to it. In these terrible pitched battles with Hyacinths between Messrs. Cutbush and Paul, the matter of foliage will sometimes almost, if not quite, decide the fortunes of the day. What is worse than to see a fine spike of flowers quite hidden within a kind of leafy palisading, as if Flora had impounded it for some crime? It is almost as bad as staging a collection of cut Roses, and omitting to take off the lid of the box. I know that some sorts, and especially among the single white and blue flowers, will throw up their foliage; nevertheless, it can be kept within due bounds if the cultivation be properly looked after.

Some pots of Polyanthus Narcissus should be cultivated for the decoration of the conservatory or greenhouse. The flowers are so powerfully fragrant, as to be almost unbearable by some persons in a sitting-room, but they should always have a place in the conservatory. Do not put a single bulb in a pot, but yoke them in couples, as two bulbs in a 6-inch pot, or better still, three in an 8-inch pot. A soil similar to that recommended for the Hyacinth can be used, and similar treatment subsequently. They are very easily managed, and well repay a little trouble. The following are fine for pot culture—Bazelman major and Gloriosa, two of the best; the yellow Grand Monarque, Musat Orientalis, Sir Isaac Newton, Soleil d'Or, and a pretty dwarf-growing variety, L'Etoile d'Or.

Those very beautiful decorative plants, the Early-flowering Tulips, must not be neglected, especially as they are admirably adapted for pot culture. I know one place where these are largely grown in pots for decorative purposes, and are in flower from Christmas till the end of May. Three bulbs should be placed in a 6-inch pot, and some sand be added to the compost recommended for the Hyacinth and Narcissus, the after-treatment being similar. The bulbs should be buried just beneath the soil.

Here are some good single varieties, not too dear in price:—Couleur Cardinal, Garibaldi, Monument, Couleur Pongeau, Scarlet Van Tuol, and Vermillon Brillant, scarlet, crimson, and deep rose shades; Paul Potter, Purple Crown, and Van der Neer, shades of purple; Proserpine, Rose Luisante, and Queen of Violets, rose; Canary Bird, Gold Prince, and Yellow Pottebakker, yellow; Thomas Moore, buff; Pax Alba and White Pottebakker, white; Duchesse de Parma, Keizer Kroon, La Cour de France, Princesse d'Autriche, Queen Victoria, Rose Gris de Lin, and Rosa Mundi, edged and feathered flowers; and Bride of Haarlem, Globe de Rigaud, Joost Van Vondel, Paul Moreelse, Royal Standard, Marquis de Wesserode, and red-striped Pottebakker, striped flowers. Of the double-flowering kinds:—Imperator Rubrorum, Bleu Céleste, Rex Rubrorum, La Candeur, Rose Eclatante, and Yellow Tournesol, self flowers; Duke of York, Gloria Solis, and Tournesol, edged flowers; and La Belle Alliance, Couronne Impériale, and Marriage de ma Fille, striped flowers.

It is a good plan, just as the flowers are fully expanded, to bind them round with a piece of fine silk. This considerably prolongs the duration of bloom, especially if they be kept in a somewhat shady position.

Then the "happy and beautiful Crocus" should be represented also. The same size of pot, 6-inch, and soil as for Tulips, will suit the Crocus admirably, and six bulbs should be placed in a pot. For earliest blooming, begin with Crocus biflorus, or the Scotch Crocus, a very pretty, though small, but singularly free-blooming form, the flowers pencilled with rosy violet on a pale ground, and the Cloth of Gold. Then for suc-

cession, the large yellow; Prince Albert, Lilaceus superbus, and Ne Plus Ultra, blue flowers; Pride of Albion, and Sir Walter Scott, both striped flowers, the former heavily so, but both fine and handsome; and Mont Blanc, and Mrs. Beecher Stowe, white varieties. Crocuses are very handsome indeed in the open ground, but their beauty is much enhanced when subjected to a little cultivation.

There are yet a few other bulbs well worthy of cultivation in pots. Perhaps the earliest of all to bloom would be the pretty and delicate Early Roman Hyacinths, in whose praise too much can scarcely be written, as they blossom profusely, and continue in flower for a long time. A pot or two of the little early-blooming Bulbocodium vernum, should not be omitted; and Scilla bifolia and sibirica, both little blue-flowering gems, should be included at all hazards, though the former is somewhat difficult to obtain. I also put in a claim for Narcissus pumila, and N. Bulbocodium, the last named the Hoop Petticoat Narcissus, and both most valuable as pot plants in the conservatory; and then to bloom later, the chaste, free-blooming Triteleia uniflora.

Just a word in praise of Crocus speciosus as an autumnal-blooming plant for pot culture. It is the gem of my small garden at the present moment. I imagine that what I have for C. speciosus is but a garden variety, but showing an improvement on the original species in point of form. About its delicate blue flowers there is a sweet chasteness, while the type I possess is floriferous to a degree almost approaching singularity. This beautiful Crocus does much in the way of linking autumn to spring; it is in the van of a floral procession that with almost unbroken ranks bridges over the parenthesis of winter, and connects the past with the future, and so

"Winter, slumbering in the open air,"

can be made to

"Wear on his smiling face a dream of spring,'

even when he holds the earth in the firmest grip of his icy hand.—Via.

WELLINGTONIA GIGANTEA.

Observing in an appeal from Mr. Robson for reports upon Wellingtonias, I send you an account of those I saw at Bicton a few weeks ago. About an acre of ground is planted with them. The soil, to the depth of about 1 foot, has been thrown up into nine large mounds about 4 feet high, and upon these mounds nine trees have been planted. I could not help thinking the situation a very unfavourable one, placed as the trees were beyond the reach of any source from which they could draw nourishment beyond what the mounds contained. One of the plants was only a few feet high, and appeared to have been recently planted, but I did not ascertain what had become of its predecessor. Another showed symptoms of declining health, and the remaining seven were tolerably healthy, but did not present a very vigorous appearance. I did not ascertain their age. Their average height is 23 feet, and the diameter of the spread of branches 18 feet. They suffered from the drought of both this year and last. It is now intended to add liberally to the mounds until the surrounding ground shall be restored to its original level.

The largest and healthiest specimen of Wellingtonia at Bicton is planted on the level ground in the pinetum. It is 30 feet high, its spread of branches 18 feet, its circumference of stem at 6 inches above the ground 6 feet 8 inches.

The Wellingtonias are bearing a good crop of cones this season, and the seed is growing well. I believe they are likely to be the first seedlings raised from home-grown seeds in Britain.—A. B., *Cudsden, Amersham.*

In reply to Mr. Robson's inquiry, I write to state how my Wellingtonias are placed, and what is the soil in which they thrive. The soil is a very rich yellow loam, and the situation of the largest tree a wide piece of lawn, surrounded by numerous other Conifers. The tree was planted in September, 1851, soon after the introduction of the species into England, and its height was then 6 inches. The Wellingtonia being an expensive tree at that time, the greatest care was taken of it. It, like all the other Wellingtonias grown here, is sheltered from all winds, many of the common Firs being planted round our Conifers to shelter them from keen winds, but though we are on a hillside, we have not such keen winds as one would imagine.

We have three trees of Cupressus Lambertiana, one being 34 feet in diameter of spread, though the height is only 28 feet, owing to the tree having lost its top a few years ago; the next is 32 feet high, and 28 feet in diameter; and the third is 30 by 26 feet. Mr. Robson's remark concerning the similarity of Cryptomeria Lobbii to C. japonica is quite true; they differ but little in their foliage, but the C. Lobbii as grown here is much more bushy and compact than C. japonica. We have four trees of Cryptomeria japonica, but they have not attained the height of that which was broken at Linton Park in 1867. We have them 35 feet high, but the spread of branches is but small. There is a Picea Nordmanniana 26 feet high, and covering a space 20 feet in diameter. I do not think this species is enough cultivated; it deserves a chief place among Conifers.

Having several plants of Araucaria imbricata, would you inform me the cause of their throwing out so much gum at the base? Is it a consequence of rapid growth? The finest specimen here is 20 feet high, but there are several 15 feet high. Some seem to grow very bushy in this soil.

I will give a list of most of our Conifers and their heights at some future time.

In conclusion I must say a few words about that noble tree, Pinus macrocarpa (P. Coulteri). We have one 20 feet high and covering a space 12 feet in diameter. Its leaves are from 9 to 10 inches long, and its cones in its native country are very large, being from 12 to 14 inches long, 6 inches broad, and weighing from 3 to 4 lbs. each. "It is," says Gordon, in his "Pinetum," "a large tree with spreading branches, growing from 80 to 100 feet high, and 3 or 4 feet in diameter, found on mountains of Santa Lucia, near the Mission of San Antonia, in California, within sight of the sea, at an elevation of from 3000 to 4000 feet. It is also plentiful in other parts of California, particularly on the 'Cruste,' an ascent from San Luis Obispo on the brow of the mountain."

The Cryptomeria Lobbii which I mentioned in my former letter has only two leaders, each from 12 to 14 feet high, not four, as I stated by mistake. The tree is 26 feet high.—The Master's Gardener.

MARÉCHAL NIEL ROSE ON A CÉLINE STOCK.

I have read with much interest the interesting articles on Roses and their stocks from pens of no mean authority. All seem to be of one accord that Maréchal Niel is a very beautiful Rose, and so say I; but there seems to be some difficulty in blooming it, and in many instances inducing it to grow. As there are differences of opinion as to the proper stock for it, I beg to offer my experience. I cannot too strongly recommend as a stock for it the Céline Rose, which is a Hybrid Bourbon of very strong growth, hardy, and the cuttings will root as freely as those of the Manetti. It will grow well in all soils, but is most at home in a sandy loam. Climate seems to make no difference to it, as it has thriven wherever I have had to grow Roses. I have never found the Maréchal nor any of the Tea or Noisette Roses die on it, although I never could grow them more than a year or two on the Manetti.

I find that in light soils for most of the Tea Roses, and especially when it is desired to have a dwarf plant of Devoniensis, the Crimson Boursault is the best stock; but if the soil is at all of a clayey nature there is nothing to surpass the Briar. Of course I am referring to Tea and Noisette Roses. Let me impress upon all lovers of Maréchal Niel and Roses of the same class never to buy or work it on the Manetti stock, for that is time and money thrown away, and will only end in disappointment.—J. T., *Macsgwynne, South Wales.*

THE CLOCHE SUPERSEDED.

Yes, I venture to write these words; and little did I think, when recording my observations on the vegetable-growing of Paris, that there was so nearly at hand for us an invention that would put it into our power to produce winter salading in quite as great perfection as our neighbours; but such I believe to be the case, and that the plant-protectors of Mr. Rendle will, amongst their various uses, be found admirably suited for this purpose, far more easily managed than frames, cheap, and durable. Every owner of a garden will now have at hand materials for raising and keeping his salads. The plant-protectors will be more cleanly than the cloche, for there will not be so great a need of heaping up manure about them in severe frost—a covering of mats being, I should imagine, sufficient. At any rate, I mean to give them a fair trial this winter, and

shall hope in the spring to report progress. I imagine that we shall find these plant protectors among the most useful inventions of recent date in gardening. I saw them at Mr. Rivers's, at Sawbridgeworth, in August, and was then struck with their usefulness for Grape-growing, and since then have been led to see that they will be most useful for many purposes, amongst others that which I have indicated above.—D., *Deal.*

MR. B. S. WILLIAMS'S VICTORIA NURSERY.

If proofs were wanted of the increase of a taste for plants, the progress of the London nurseries within the last few years would be one of the best; for that progress has not been confined to one nursery, but has extended to nearly all, and although a few old, well-known establishments have disappeared to make way for the rapid development of London, the majority have only receded before the advance of buildings to reappear, at a distance from their former sites, on a greatly enlarged scale, and with appliances more complete; while in the case of others which have not been removed, subsidiary nurseries have been added at a distance from the principal one, to which they serve as feeders. Mr. Williams, however, has not been driven from his old place of business by bricks and mortar, for he still keeps it on; but probably foreseeing the likelihood of its being built in if not built over, and finding, too, that its area was too circumscribed, he formed, five or six years ago, his Victoria Nursery opposite the Archway Tavern at the foot of Highgate Hill, making it his principal place of business. Here no adaptation of existing means could be attempted; everything had to be made new, and on a scale suitable to Mr. Williams's requirements, and everything from beginning to end was carried out according to his ideas, and under his own supervision. Of the conservatory and show house, soon after its completion, an illustration was given in the seventh volume of this Journal, and its general appearance now is not essentially different, though many of the specimens are very much larger, it is better filled, and the arrangement has been altered. The value of the plants in this house alone, 105 feet by 45 feet, is at a rough estimate £3000. It is essentially a house of fine-foliaged plants, a home of grace and beauty, but not of colour, for though flowering plants are not excluded, they play but a subsidiary part. Here we find noble tree Ferns, black-trunked and aged, with graceful wide-spreading fronds, stiff-formed Yuccas and Dracænas, and Palms with their fan-shaped leaves spread out as it were to shield from the burning rays of a tropical sun. And these are mingled with dark glossy-leaved Camellias, with brighter-coloured Ferns, and with a multitude of other plants, affording by their foliage a diversity of form and hue. Most of the larger specimens are arranged in pairs on the opposite sides of the main walk leading past the fountain, and the most remarkable are Chamærops humilis and Fortuni, Dracæna lineata 14 feet high, Dracæna indivisa, Dicksonia antarctica, Cyathea princeps, C. Smithii, Cycas revoluta, and Yucca aloifolia variegata, at least 7½ feet high. A pair of the Dicksonia is especially remarkable; one plant has a trunk measuring 1 foot 9 inches in diameter at the base, and standing about 13 feet high from the ground, while there is another specimen with not quite so thick a stem, but of even greater height. Cordyline indivisa latifolia is another noble plant; its leaves are 6 inches broad, and have the orange midrib very conspicuous, but whether these are permanent characters or peculiar to the individual, remains to be seen; in the former case the plant cannot fail to be sought after.

The collection of Yuccas, Agaves, Beaucarneas, and Dasylirions along the side shelves is large, and many of the specimens are remarkable either from their size or rarity. Yucca Stokesii having a broad band of yellow in the centre of each leaf, Yucca albo-spica, Dasylirion acrotrichum and plumosum, Beaucarnea longifolia with leaves 7 feet long, a very graceful plant for a pedestal in front of mansion in summer, and Beaucarnea glauca having a large woody rootstock, are a few of the most noticeable, but there are many more remarkable in various respects. There are, besides, on the shelves numerous specimen Azaleas and Heaths out of flower, and near the entrance a very large specimen of Eucharis amazonica, invaluable for its continuous flowering, and for cutting for bouquets, and near this, in the body of the house, are four fine specimens of Yucca quadricolor. Of Lapageria rosea, two large balloon-trained specimens were producing a few flowers, and there were several large Camellias equally grown and well set with buds, especially Bonomiana and a pair of the old Double White.

The stove contains a splendid collection of Palms, several of them being very large specimens, and new introductions are amply represented; Areca Baueri, Areca Verschaffelti, Dion edule, Livistonia altissima, and some others being very large, while younger plants are numerous.

The next house contains fine-foliaged and flowering stove plants, consisting of Allamandas, Ixoras, a fine pair of Theophrasta imperialis, Crotons, a noble Cycas circinalis showing for fruit, and with some of the old fruit remaining; Mussænda frondosa, always producing its white calycine leaves; Rondeletia speciosa just coming into flower, and which will probably produce a succession of bloom up to Christmas or later; and Anthurium Scherzerianum, which, though exhibited at almost every large show this year, is still in bloom. Here too, in flower, is Posequeria longiflora, which is but rarely seen, but deserves to be more generally cultivated on account of its extremely fragrant white flowers, which are produced in long succession, the plant under notice having borne two sets of flowers since May, and is now forming buds for a third bloom. Rogiera gratissima, a recent introduction, appears to be valuable from its frequent flowering, and its flowers are pink and sweet-scented. There are in this house excellent plants of Gold and Silver Ferns, some of which are grown on sections of the trunks of tree Ferns, an idea of Mr. Williams's; and elsewhere he has Ferns of other kinds grown in the same manner, so as to allow of the fronds drooping more than they would naturally do, and, according to taste, forming miniature tree Ferns or not. At the back are a number of specimen Rondeletias, Franciscea, &c., at rest, and on shelves a large stock of young plants, both flowering and fine-foliaged.

Next comes the cool fernery, in which are remarkably fine specimens of Cibotium princeps, C. regale, a new and handsome species, having the caudex covered with shining fawn-coloured hairs; Lomaria cycadæfolia, with a thick trunk 2 feet high; Gleichenia speluncæ, the rare Cyathea contaminans, besides a large stock of young plants of various genera.

A house filled with Heaths, Camellias in 48-pots, and New Holland plants, with a large collection of the Amaryllis tribe under the stages, is the next in order; then follow the Orchid houses, containing one of the richest collections to be found in the country. Mr. Williams's success as an Orchid-grower and exhibitor is so well known, that comment on that subject is unnecessary, and, as will be readily supposed, his collection, including not only the newest introductions and many unusually large masses of older ones, is in perfect health. The time of our visit was not the most favourable for seeing a large number in flower, still in the cool house Lælia elegans and gigantea, Lycaste Skinneri, Cattleya labiata and Lodigesii, several Odontoglossums, as Alexandræ, bictonense, and grande; Oncidium ornithorhynchum, with small sweet-scented lilac and orange flowers; the fine new Dendrobium Bensoniæ; and Maxillaria venusta with pure white and orange flowers, besides some other species, were blooming, and some of them profusely. Oncidium obryzatum, which is very useful on account of its free flowering; Mesospinidium sanguineum, with pretty little red flowers; and Miltonia Clowesii, conspicuous by its rich violet lip, were the most noticeable of the remainder.

Next is the East India Orchid house, containing a very large collection of Vandas, Aërides, Saccolabiums, and Cypripediums, many of them unusually fine specimens, and all in excellent condition. Flowering in this house were Angræcum eburneum, several Cypripediums, and the pretty Dendrobium triadenium, which, though the spikes are small compared with those of other species of the same family, has the merit of blooming several times a-year. Phalænopsis rosea, another Orchid valuable for its continuous flowering, was also in bloom. Of Phalænopsis Schilleriana, though not in flower, yet ornamental by its foliage, there was a remarkably fine specimen, and large plants of Aërides, some, as A. Larpentæ and crispum, being in flower. At the end of this house, as there is with most of the others, a portion is cut off as a potting house, where plants can be cleaned, repotted, and otherwise attended to in a suitable temperature without exposure in a shed or unheated potting house. These little potting compartments are further utilised for the culture of collections of plants not numerous enough to require one of the larger houses to themselves. Thus, in the case of the East India Orchid house, the potting compartment is occupied with a collection of those curious North American Pitcher Plants, the Sarracenias, and shut off from these by a kind of tiffany screen, is a beautiful collection of Filmy Ferns, among which Todea intermedia and superba, and the rare Trichomanes reniforme, were conspicuous.

A stove filled with a mixed collection of fine-foliaged plants, and others in flower, formed an interesting feature. In this we noticed magnificent specimens of Croton variegatum, angustifolium, and variegatum pictum; handsome plants of those noble Palms Stevensonia grandifolia and Verschaffeltia splendida, and of Alocasia metallica, zebrina, and Lowii; Marantas of the newest and best kinds; Fittonia argyroneura; and under the stage Gynostachyum Verschaffelti at least a yard in diameter, a magnificent specimen, which Mr. Williams exhibited at the International Horticultural Exhibition of 1862. Dracænas, both new and old, the new Crotons, Eranthemum igneum, a young stock of Bertolonias, and a host of other beautiful-leaved plants are also grown here. There is also a collection of Pitcher Plants, Nepenthes Rafflesiana and Hookeri having very fine pitchers. Many of these are grown in baskets filled with sphagnum and a little peat, and suspended from the roof. Thus treated they have a much better effect than in pots, the pitchers at the ends of the leaves hanging down over the sides of the wire baskets. Among plants in flower were large specimens of Dipladenia crassinoda, Franciscea calycina, which blooms in long succession, Ixora coccinea, and Ixora javanica; but showy as the latter is, Mr. Williams states that it is surpassed by the new Ixora princeps. Cochliostema Jacobianum, another new plant, also deserves especial mention, as having handsome foliage as well as large panicles of flowers.

Several other houses were occupied with Azaleas of various sizes, from large exhibition specimens down to plants in 9-inch pots; Camellias in tubs imported from the Continent, and Camellias in small pots; Heaths and Aphelexes; Boronias, Genetyllis, and various New Holland plants; Coleuses, Fuchsias, Zonal Pelargoniums of different sections, and a variety of other plants too numerous to mention in detail. A collection of those beautiful but now neglected bulbous plants, the Nerines, deserves notice, even though they were not in flower, for they are so rarely seen, and some of them, as N. coruscans major, have very showy flowers.

The Pine stoves are a sight in themselves, containing such a stock of plants in all stages as one could probably find nowhere else about London; and of Vines, too, there is an excellent collection of well-ripened canes, including Mr. Thomson's White Lady Downe's.

UNITED HORTICULTURAL SOCIETY.

At the monthly meeting of this Society, held at the Green Dragon Hotel, Bishopsgate Street, October 11th, Messrs. E. G. Henderson and Son, of Wellington Road Nurseries, St. John's Wood, exhibited the following plants—viz., Achillea umbellata, a very dwarf and compact silvery-leaved plant, to which a first-class certificate was awarded as being useful for edging and surface purposes; Bouvardia jasminiflora, a new white, free-growing and flowering kind, highly scented, blooming in autumn and winter, which must be a good addition to our cool greenhouse plants, and to which a first-class certificate was given; Coleus Emperor Napoleon, with intensely dark foliage, of dwarf robust habit, hardy constitution, and said not to drop its leaves when exposed, like most of the other Coleuses, and a plant likely to prove a rival to the well-known Perilla for bedding purposes—Messrs. E. G. Henderson were requested to exhibit this again;—and Crassula Cooperi, a pretty little free-flowering plant, 2 inches in height, and which from its dense habit will be a useful plant for marginal rows.

An interesting paper on coloured-leaved plants was read by Mr. R. H. Bard, of St. John's Wood, stating the merits and cultivation of many of these.

NUNEHAM PARK ONION.

Seeing Mr. Cuthush's letter inviting your readers to give reports of the different kinds of Onions grown by them, I send the result of a trial carried out on a very small scale in a small garden in a cold district of North Wales.

The beds were 15 feet long and 4 feet wide, and the seed sown about the end of March, six rows in each bed. All received the same treatment. The crop of Nuneham Park weighed 71 lbs., of White Spanish 51 lbs, James's Keeping and Brown Globe not 50 lbs. The seed was brought from a house celebrated for their strain. Would 71 lbs. be considered a heavy crop for a bed 15 feet by 4 feet in Onion-growing districts?—Cymro.

I quite agree with Mr. Cuthush's opinion of this Onion. I believe it to be the best in cultivation. I sowed with it this spring a plot of ground 6½ yards long and 2 yards wide in a very hot and dry situation, and I have harvested in the middle of August 156 lbs. of beautifully shaped and sized Onions. The necks are now no thicker than common twine. I exhibited it at two horticultural shows this summer, and took the first prize at both of them. There were fifteen competitors at one, and nearly as many at the other.—T. C. Tunnicliffe, *Longdon.*

In 1867 I procured a packet of seed of the Nuneham Park Onion, and sowed it along with many other sorts. On taking them up I found the Nuneham Park superior to any, Danvers' Yellow being the next best.

Last year I saved my own seed, and this year sowed it side by side with Danvers' Yellow, and I have no hesitation in saying that the Nuneham Park is far better in every respect.

The seed was sown on the 27th of February in drills 18 inches apart, the plants thinned out to 6 inches in the row, and with the exception of hoeing, nothing else was done to them till harvested three weeks ago. Taking them on an average, they measure 14 inches round; some are 17 inches, and weigh 1 lb. 10 ozs.

In case there should be any doubt respecting my statements, I send for your inspection a fair average sample.—A. Donaldson, *Latimer Gardens, Chesham.*

[The Onions sent to us by Mr. Donaldson were very fine. Not one of them was thick-necked. They were flat in form like the Silver-skinned, and as mild as the mildest imported Spanish. It will not be necessary to insert any more communications on this subject.—Eds.]

GLÖEDE'S PERPETUAL PINE STRAWBERRY.

I think there has been too hasty a condemnation of this fruit. I can easily understand why it was; nevertheless, the fact, it seems to me, remains. My friend, Mr. Radclyffe, gave me half a dozen plants of it, and I felt very much inclined to throw them away this year, but they were left, and during the present month I have gathered at various times some very good and well-flavoured fruit. Had I possessed a couple of rows, I have no doubt that I should have been enabled to gather a dish two or three times. Now, it may not, and does not, deserve the name of Perpetual Pine, but if we can obtain a Strawberry that will produce fruit for us in autumn, surely it must be an acquisition. Judging from its habit, and the wiry nature of the connecting portion of the runners, I should think there must be some of the Alpine blood in it, although the fruit has none of that flavour. At any rate, I am going to try it again, and shall report progress.—D., *Deal.*

COLEUS PLANTS RAISED FROM LEAVES.

I have just exhibited a set of sixteen Coleus plants at our autumnal show, and taken the first prize. The officers and others of the Royal Jersey Society have requested me to write and mention that I have succeeded in rooting the leaves of these ornamental plants, and several of my standards had the whole of the soil in the pot covered thickly with all the various leaves of these handsome plants, the standard starting from the centre. I cannot say at present whether or not I shall succeed in raising plants from the leaves, as is the case with Gloxinia, Lime trees, &c., but I think so, as they root so strongly and healthily.

These handsome leaves make a most beautiful edging for dessert dishes, by placing the glass in an earthenware pan sufficiently large to allow of leaves being placed all round it. They root easily with a good damp bottom heat, and will, I should say, last a long time. My pans have been growing for two and three months. I believe, from what I am told, that this is a novel discovery.—R. E. Knatchbull, Col. R. A., *Jersey.*

[Mr. Wills, Ashburnham Park Nursery, Chelsea, has raised Coleuses from their leaves.—Eds.]

LIBONIA FLORIBUNDA.

Amongst the plants recommended in "our Journal" for winter flowering, I have wondered at never seeing mention of Libonia floribunda, known also as Abutilon megapotamicum and A. vexillarium. It requires so little attention, and this, added to its protracted continuance in bloom, renders it deserving of a place in every collection. It is with me a great favourite. All that is necessary to be done is to give it a little warmth in the spring after flowering, to help it into growth,

to be turned out of doors in the summer with the Azaleas, &c., and now (October) a fine plant will be the result, with every shoot completely covered with flower buds ready to burst forth at the least excitement; and the flowering once begun will continue nearly the whole of the winter.—H. Harris.

MR. LAXTON'S PEAS.

Now that the Supreme Pea controversy seems to have subsided into something like a sensible climax in your correspondent "J. W.'s" letter, I may, perhaps, be permitted, without the risk of doing Messrs. Carter & Co., and Messrs. Hurst an injustice, to state what I believe to be the cause of the extremely wide differences of opinion amongst your correspondents respecting this Pea.

The character I, as a foster-parent, have always had and given of my progeny is, that it is a second early Pea of the Prizetaker class, in height from 4 to 5 feet, and, consequently, requiring to be sown at about such a distance from row to row, and I could have wished the vendors had taken their description either from mine or from observations extending over more than one exceptional season, for I fear this has been the cause of the mistakes which the majority of those who have failed with it have made. In most cases where this has occurred, I have found that it has been treated as an early variety of the style of Sangster's No. 1, and consequently disappointment has been the result; whereas Supreme, in my opinion, has sufficient to recommend it without needing to be sent out as an early dwarfish Pea. Supreme was selected by me as by far the most striking for its deep green colour, length of pod, and productiveness, out of hundreds of varieties, the results of crosses between Laxton's Prolific and Little Gem. For earliness, I do not even consider it a competitor with modern varieties. I have, however, its early type in William the 1st, which runs about 2 feet 6 inches high, and was the earliest deep-coloured selection of the long-podded class from the above crosses. This has proved itself, both here and at Chiswick, to be the best of all the early Peas, and will in its turn, I believe, supplant most of the earlies requiring short sticks.

Of the dwarfer varieties I have many earlier and superior to Little Gem, but of these a limited number of the very best only will be allowed to make the public acquaintance; and I regret here to have to allude to the fact that so-called varieties have, without my authority or even knowledge, been publicly exhibited as Laxton's and to which it would seem I am expected to stand *in loco parentis*, as if I had not a large enough family of my own. Amongst the numerous adoptions I have in prospective from my own family, are dwarf varieties between Veitch's Perfection and Ne Plus Ultra, and many taller varieties of different breeds at present quite unapproachable for size, beauty, colour of seed, and distinctness, but as I yearly select from many hundreds of crosses and varieties, with the object of allowing only a very few of the best to see the public light, some time must elapse before these can all be in the hands of the gardening community.

In conclusion I would recommend your readers to give Supreme the same space as Prizetaker and Laxton's Prolific, and to sow as early in the year as soil and circumstances will permit, for I have found the later sowings usually neither so fine nor so productive as the earlier. The true Supreme has a roundish blue seed, and a long deep green pod, coming in a few days after Prolific, and, as one of your otherwise adverse correspondents stated, approaches Ne Plus Ultra in flavour if it is not gathered too old. The exceptionally extreme seasons of the past two or three years may, in conjunction with the above suggestions, reconcile some of the wide discrepancies between the results obtained by your correspondents, but I fear it is not given to me nor any other mortal to explain them all.—T. Laxton.

GROWING GRAPES FOR PROFIT.

Which is the more advantageous in a pecuniary point of view, the early forcing or non-forcing of Grapes for the market? Supposing one has early sorts of strong established Vines four years old, do you think forcing them in the first year (to begin) to be ripe, say, as early as June, in the second year by May, in the third year by April, giving them a rest every fourth year, would hurt them?

And supposing good Grapes to be obtained for the markets at the above periods, do you think they would pay as well as very late sorts from equally good Vines, brought in very late every year, say ripe for market from October to March, after deducting from forced Vines all expenses of fuel for forcing, and allowing the fourth year as a rest?—A. B.

[Where fuel is at all reasonable, forced Grapes will pay better than late ones, as Grapes from houses in winter have to compete with good foreign Grapes. The questions, however, are such that we should like the opinion of growers experienced with the London market.]

THE VEITCH MEMORIAL.

In accordance with a desire which has been freely expressed amongst horticulturists, that a memorial to the late Mr. James Veitch should be established, a meeting was held yesterday in the Royal Horticultural Society's Council Room, South Kensington, to take action in the matter. James Bateman, Esq., F.R.S., occupied the chair; and amongst those present were Dr. Masters, Messrs. G. F. Wilson, T. Moore, Standish, Gibson, Z. Stevens, A. Salter, J. Douglas, G. Tillyard, W. Robinson, W. Dean, J. Rust, F. Rutland, T. Monro, C. Penny, Smith, of Dulwich, &c. After some preliminary observations by the Chairman, Mr. T. Moore read numerous letters of adhesion to the projected memorial, containing propositions almost equally numerous as to the form it should take. The Chairman summarised these under two heads—practical, and memorial. Of the former, the best appeared to him to be those instituting medals or prizes either for new plants or good specimens of cultivation; of the latter, a monument or portrait. Now, a good portrait might be obtained for £50, a bad monument for £500, and where, as in Mr. Veitch's case, the family themselves were in a position to erect a monument, he was strongly inclined to the portrait.

G. F. Wilson, Esq., cordially agreed in the suggestion of a portrait as the most fitting memorial. He then moved the first resolution—That a desire having been expressed to perpetuate the memory of the late Mr. Veitch, this meeting, fully appreciating Mr. Veitch's claims on the grateful remembrance of horticulturists, and the loss his family and they have sustained, effect shall be given to this desire. This resolution having been seconded by Mr. Gibson and carried unanimously, Dr. Masters proposed, and Mr. Standish seconded, the next, that a Committee be appointed. The third resolution, proposed by Mr. W. Dean and seconded by Mr. Rust, was that the Committee be authorised to obtain subscriptions, and that Mr. G. F. Wilson be Treasurer; and the fourth, moved by Mr. Standish and seconded by Mr. Gibson, that Mr. T. Moore be requested to act as Secretary. It was further decided that the subscription list should be closed on Lady Day next, and that gardeners' subscriptions be limited to a guinea. As it was conceived the amount raised would far exceed the cost of a portrait, the meeting considered that the latter might be supplemented by prizes for good cultivation, whether of plants or fruits, and it was carried unanimously that no medal should be struck to be called the Veitch medal, but that any prize should be called simply the Veitch prize, and might be awarded in money, or otherwise, as might hereafter be decided. Several suggestions were made as to the subjects for which these prizes should be awarded and how they should be competed for, but the details were left to the Committee, and after a cordial vote of thanks to the Chairman, moved by Dr. Masters, the proceedings terminated.

The names of the General Committee, of the separate Committees for England, Scotland, and Ireland, as well as the resolutions in full, will be found in our advertising columns; and we have only to add that those desirous of sending in their contributions at once towards the proposed memorial may forward them to G. F. Wilson, Esq., Treasurer of "Veitch Memorial Fund," care of Mr. Richards, Royal Horticultural Society, South Kensington, London, W. Further, local secretaries, who have yet to be decided upon, will be empowered to receive subscriptions towards the object in view, and their names will appear in due course.

APPLICATION OF MANURES.

In No. 442 of this Journal, at page 221, is an article under the above heading, by Mr. Pearson, in which he says a correspondent lays great stress on the necessity of covering manure as soon as possible after it is spread, and Mr. Pearson calls it "mischievous, not only because it is erroneous, but because it leads to injurious practice." I, for one, would feel greatly obliged to Mr. Pearson if he would be so kind as to describe why it is erroneous, and how it can lead to injurious practice, for I am of the same opinion as the correspondent he

alludes to, and I should be sorry to continue in error. I quite agree with Mr. Pearson as to carting on ground when it is dry, for I have seen enough of the evil effects of carting out manure when the ground was wet, and also ploughing when the horses walked in the furrows up to their knees in mud. I have seen after such ploughing, the water run out at the end of the furrow in quite a stream, and I have had it remarked to me at the time, what excellent ploughs those iron ones were, for they left the bottom of the furrow so smooth that they actually drained the ground; but when spring came, and the land was ploughed up again it was nearly midsummer before it was fit to be sown. I cannot think that it is quite right to have a quantity of good rotten farmyard manure exposed to wind and sun for days before it is ploughed in; for my own part I would prefer it to be under the ground. I could mention several farmers here (in Kent), who have only enough manure spread to be ploughed in each day, because it should not be dried up by wind and sun. Of course it was carted out and left in a heap to be spread as above.

I have had sufficient proof this year that there cannot be much evil attendant on diggiug in manure soon after it is spread, for the principal part of the manure that I have for use consists of old hotbeds made of leaves collected in the park, and which, after being used, are wheeled on the garden as manure, and not being quite decomposed, the material is not very rich. One of these old beds I had wheeled into a corner of the orchard, to which I conducted the overflow from a large tank that receives the sewage from the mansion, and after giving a good soaking of the sewage, I had the whole turned over so as to well mix the sewage with the half-rotten leaves. I then had it wheeled on to a plot of ground intended for Onions, and dug in immediately, and the result was the finest crop of the Nuneham Park Onion I ever saw, not thick-necked, as some affirm it to be, but fine-necked and clear-skinned. I think it is the very best Onion we have when it is well grown. The remainder of the heap I kept for Celery, and I gave that another soaking of sewage, after which I had it put into the trenches, and the Celery does not show any evil effects, but the contrary. It is a fact known to most practical gardeners that all manures must be rendered soluble, as no solid substance can enter into a plant, consequently all solid matter must undergo a species of dissolution, and become watery or gaseous, or both, before it is capable of being absorbed either by the roots or leaves of plants; and if manure loses the water by evaporation, it must also lose a certain portion of the gaseous matter, which must be a loss to the crop it is intended to benefit. In this opinion I think I am not alone, but I should like to hear the opinions of other practical horticulturists on the subject.—W. Graves, *Mabledon Park Gardens.*

FORCING PLANTS.—No. 3.

SHRUBS.

Shrubs are of easy culture, and many, if not all of them, are suitable for forcing; but there are some which from their low growth, compact habit, and profuse blooming, are better for the purpose than others. To enumerate and treat of all shrubs which might be forced, would be tedious. I shall, therefore, only name those of acknowledged excellence.

Deutzia gracilis.—This plant cannot be too highly recommended for forcing. The flowers are pure white, and produced so abundantly as to hide the bright green foliage. Previous to forcing it should be grown at least a year in pots large enough to hold the roots without cramping them. A rather light loam, enriched with leaf soil, will grow it well. The plants should be placed out of doors in a sunny situation during the summer, and be plentifully supplied with water, pinching back any irregular shoots, so as to form a compact plant. Until August they may remain plunged in coal ashes, moving the pots occasionally to keep the plants from rooting through, and taking off any roots that make their way out. After August lift the pots from the ashes, and set them in a warm situation, watering just enough to keep the foliage fresh. The plants will go to rest early; then place them in a cold frame, though they may remain outside with the pots plunged to the rim in coal ashes; but I like them in a frame, for then the soil is not saturated by heavy rains, and comparative dryness appears to act as a sort of rest.

The plants may be forced almost as soon as the leaves have fallen, but they are the better of a month or six weeks' rest. Prior to placing them in the house I think it well to repot them, giving each a clean pot and a little fresh soil, for though we repot we need not increase the size of the pot, but we should remove as much of the old soil as we can, without destroying many of the roots, loosening the sides of the ball, and even if we slightly increase the size of the pot, we have freer growth and bloom. Neat plants may be grown in 6 inch pots, and larger plants will, of course, require larger pots; but I do not try to have any in larger pots than those 9 inches in diameter. Plants in pots of the latter size, and grown from 18 inches to 2 feet high, and as much in diameter, are fine for house decoration, and those in 6-inch pots are ornamental for the table. This is all the potting I give. They are placed in a cool house for about a fortnight, then in a greenhouse or other glass house, with a temperature of 45° from fire heat, and are bloomed in a temperature of 50°. I commence forcing the first lot of plants at the beginning of December, introducing more at intervals of three weeks up to March, so as to have a succession of bloom from January to May. After the plants have flowered they should be continued under glass in a light airy position until the middle of May, and then be placed out of doors in a sheltered but open situation, plunging the pots to save watering, giving, however, plenty of water throughout the summer, and in autumn they will be even finer plants than they were the year before, and fit for being forced again. From having made their growth earlier than plants not forced they are better fitted for early flowering. In this way they may be grown for a number of years without increasing, or but very slightly increasing, the size of the pots.

Deutzia scabra.—This, though not equal to the preceding, is very ornamental when grown as a low standard 2½ feet or 3 feet high, taking away the flatness of stages. On a stem about a foot high it forms a charming bush. It requires a year or two to bring into good form, and establish it in pots. The only difference in the treatment it requires from that of D. gracilis, is that all suckers must be kept down; the shoots after flowering being thinned out, stopping such as grow irregularly, and not commencing to force until January or February. Being of stronger growth than D. gracilis, it must have correspondingly larger pots; but the plants are all the better by being pot-bound.

The Deutzias are propagated by cuttings of the firm shoots under a hand-glass in summer, or by strong shoots in autumn inserted in a sheltered situation. They may be propagated by layers very freely.

Prunus triloba (sinensis) flore-pleno.—Of erect, stiff habit, it forms a neat pyramid, and the flowers are large and very double, white, but going off blush. It succeeds best in a rather sandy or light loam, with one-third of leaf soil or sandy peat, and good drainage. It should be under-potted; indeed, to flower it well it should be pot-bound. Its treatment does not differ from that of the Deutzia gracilis, only the plant should be placed under a south wall in August to insure the ripening of the wood, giving only enough water to keep the foliage fresh. When the shoots become crowded thin them out after flowering, stopping any which are of a straggling disposition. It flowers before coming into leaf, but is very ornamental. It is propagated by cuttings of the ripened shoots in summer.

Amygdalus persica flore-pleno (Double-flowering Peach).—There are varieties with white, carnation, crimson, and rose-coloured flowers, also one called versicolor, all very ornamental as pot plants for conservatory decoration. They may be grown as bushes or pyramids, following the close-pinching system, so as to have them compact and well furnished for bloom; but when the wood becomes weak the flowers are smaller; therefore to ensure large flowers thin out the weak shoots when the flowering is over, and by stopping the strong shoots to four leaves the weaker shoots will be strengthened. Whether the shoots are close-pinched or allowed to make shoots of some length, it is desirable to so dispose of the shoots as to produce a well-formed plant. Standards are very handsome.

The treatment given Peach trees in pots is applicable to these. The trees ought to be kept under glass until the end of May, and may then be placed out of doors in a warm situation—a south border is best—the pots being plunged in ashes, watering and syringing freely in dry weather. In August place the pots under a south wall, but do not plunge them, and water rather sparingly, so as to limit growth and encourage the ripening of the wood, but do not allow the soil to become so dry as to cause the leaves to fall prematurely. In October top-dress the plants, taking away the surface soil, and removing it to some depth from the sides, leaving the mass of roots in the centre of the pots undisturbed, and replace with turf enriched with an equal quantity of well-rotted manure. Old cow dung

is best. Make the top-dressing firm, and give a good watering. At the same time the plants may be housed, or they may be placed in a sheltered position, the pots being plunged to the rim in ashes or tan.

Forcing may commence at the end of November or beginning of December, and by introducing a few plants at fortnightly intervals bloom may be kept up from January to April. The plants may be kept a number of years in the same pots; those from 8 to 13 inches in diameter are suitable.

These Peach trees are mostly worked on the Plum stock, but the Almond is best for this class of plants. Early-forced plants should be continued under glass in a light airy position until danger from frost is past; or if they can be accommodated in a house it is well to keep them there until July or August, and then by placing them in the full sun and giving little water they will go to rest and be suitable for forcing early in November. Few plants are handsomer than Peach trees in pots in full bloom, but the double-flowered varieties surpass the ordinary kinds in the greater beauty of the flower. A temperature of 40° for a fortnight, increasing it to 45° afterwards, is sufficient. Liquid manure may be given once or twice a-week.

Cerasus japonica.—Pink, double pink, and double white varieties, all dwarf and compact. The double varieties are the strongest growers. The treatment is the same as for the double-flowering Peaches.

Spiræa Fortuni.—A shrubby plant of compact growth and white flowers, and Spiræa Thunbergiana, also with white flowers, are fine for forcing, as they furnish pretty, loose, spray-like heads of bloom for vases and bouquets, whilst as flowering plants they are very ornamental. Probably there are many others of this genus equally suitable for forcing. S. japonica I know forces well. The Spiræas are among the handsomest of flowering plants, and it is remarkable they are not more extensively cultivated. They may be grown in pots from 6 to 9 inches in diameter, according to size of the plant, using a compost of two-thirds sandy loam, and one-third leaf soil. All the care they require is to keep them in small pots for the size of the plants, to repot them before beginning to force, to thin out the weak wood after flowering, to lift them from the plunging material frequently in order to confine their roots to the pots or keep them from rooting through, and to place them in a sunny situation in August so as to well ripen the wood. The plants should be established in pots before forcing, which should not begin before January, introducing a few plants at a time up to March.

Weigela rosea and its varieties Stelzneri and Treloni are fine, the flowers being rosy pink in the species, and somewhat brighter in the varieties. Nothing, however, can be more handsome than the old sort well grown, and it has the advantage of being fragrant, hence the flowers are desirable not only on the plant, but for cutting. It succeeds under the same treatment as described for the Deutzia, but being a larger growing plant, larger pots are necessary, and yet the roots should be rather confined. Place the plants in a warm situation in August, water them sparingly, so as to have the wood well matured and induce early rest, especially for plants required to bloom early. The roots, from their close-matting tendency, sometimes choke the drainage before forcing, therefore see that the drainage is free. The plants may be forced in consecutive years, like the Deutzias, or fresh plants may be raised from cuttings in summer, either under a hand-glass or in a shady border. Small plants flower freely.

Weigela amabilis and alba, the one with pink, the other with white flowers, are also fine for early flowering, and force well.

Syringa (Lilac).—The Persian purple and its white variety, from their smaller growth, are, perhaps, the best, though the others are equally good for forcing. Plants set with buds should be taken up in November, preserving a good quantity of fibres, and placed in pots large enough to contain the roots. Sandy loam is a suitable soil. The plants may be taken up and potted as required, but to make sure, it is as well to pot as many as will be required in November, and those not wanted for immediate forcing can have the pots plunged in coal ashes in a sheltered place, whence they can be draughted into the forcing house at intervals as required. A house with a temperature of from 40° to 45° will suit them for the first fortnight, and then from 50° to 55° is the highest night temperature they ought to receive, though I have seen them placed in a stove and roasted into flower, the stalks being then scarcely able to support the heads. For blooming at Christmas, forcing should be commenced in the middle of November. The plants are usually thrown away after flowering, though they might be planted in shrubberies advantageously.

To have subjects eligible for forcing, there should be plants of various ages up to six years, so as to have them of different sizes; therefore all vacancies must be made good by putting in suckers every year. The plants should be removed every year if they grow vigorously, so as to cause more sturdy growth and the formation of bloom buds. Standard plants are very useful for varying the monotony of flat surfaces, but are somewhat difficult to form, from the tendency to produce suckers. The white Lilac is less disposed to produce these than the others, and it might be employed as a stock. Whether as standards or half-standards, respectively 6 feet and 3 feet high, with good heads they would be really handsome for conservatory decoration. How they would succeed grafted standard high on the Ash, is a subject for experiment; but it is worth a trial.

When forced, the Lilac requires to have an abundant supply of water, and a light, airy house, with bottom heat if it can be secured. Growing plants in darkness, in order to produce white flowers on purple-flowering plants, or even to make white flowers more delicate, is absurd, though it certainly is curious to see the change undergone by a plant grown in darkness day by day. When it is exposed to light, how it strives to get back its natural beauty!—G. Abbey.

GARDENING IN TEXAS.

Although gardening here does not generally receive so much labour and care as it does from many northern people—especially those who have market gardens near large cities—among the farmers of Texas, yet we have many, very many good gardens. Some of our gardens, in the variety and excellence of their vegetables, and the number and beauty of their flowers, are superior to those commonly seen in the northern States. Here, ladies often superintend and work in the gardens, and ladies generally better appreciate good vegetables, and enjoy more the beauty of flowers, than men. Previous to the late civil war, it was customary, throughout the entire south, for planters' wives and daughters to have charge of the garden. It received much of their care, and was tilled under their direction. This custom still extensively prevails in Texas. Under the superintendence of ladies, some of the finest gardens and grounds in the entire south were made. Many of those in the vicinity of Charleston and Savannah were thus formed. To specify examples in other places, we mention the Preston or Hampden garden, as it was, at Columbia, before the war; also the Magnolia Grove garden of Mr. Brown, beneath the hill on the banks of the Mississippi, at Natchez. I have seen many beautiful gardens in the northern States, but never anything equal to what these were in 1858.

To return to Texas. Our climate and soil is better suited to gardening than that of the north. Here we can grow all the vegetables and flowers cultivated in the north, also many others of a semi-tropical nature. Two crops of the same species of vegetable can here be grown in the same season. Many people in Texas consider August the most important in the year to make gardens, because many vegetables then sown or planted attain maturity, and their greatest perfection, during the cool months of autumn, such as Cabbage, Broccoli, Cauliflower, Kale, Savoys, Endive, Brussels Sprouts, Celery, &c. Then (August) Melons and Cucumbers are again planted, also Beans and Peas. Then, and in September, are sown Radishes, Lettuce, Curled and Water Cress, Parsley, Onions, Parsnips, Spinach, Carrots, Leeks, Beets, &c.

In our own garden, we had green Peas and Beans in April, green Corn in May, also summer Squashes and Cucumbers; Lettuce and Radishes in March; white Potatoes the 1st of June, and Sweet Potatoes the 1st of August. Indeed, with a little care, by planting in succession, we can have in our garden a plentiful supply of fresh vegetables for table use during the entire year. This is a great advantage, which is not generally appreciated here. Our Melons are delicious. One Water Melon, weighing 60 lbs., was sold in the market at Austin this summer. Water Melons become ripe here about the last of June, and last until frost, which generally comes about the last of November. They are remarkably healthy, and much superior in taste to those grown in the north.—(*American Gardener's Monthly.*)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Make it a rule never to allow the haulm or leaves of plants to remain on the ground when the crop is gathered. A conve-

nient place outside the garden should be appropriated to the garden refuse; and before the leaves, &c., are wheeled to the heap, let a sprinkling of ashes or charred refuse be placed over each layer, by which a heap of valuable manure will be formed. When the ground is dry proceed with digging up vacant spaces, throwing the land into ridges, that it may be effectually exposed to the influence of frost. It should be a rule to double-spit or trench land every alternate year at least; but when two crops are taken off the same place yearly, trenching should alternate with digging every time the ground is cropped. On the first fine morning take up *Beet* and *Carrots*, and spread them on the surface to dry till afternoon, when they may be removed to the storing room and there spread out again till they are quite dry, after which they may be stored in dry sand. Constant attention will be necessary for some time in examining them to see how they are likely to keep. Remove the decaying leaves from *Brussels Sprouts* and *Broccoli*, and from all other growing crops, carrying them at once to a piece of ground if vacant, where they can be trenched into the soil, sprinkling them first with quicklime to destroy the snails and slugs with which they swarm at present, as well as to hasten decomposition. Stir the soil among *Cauliflower* plants under hand-glasses, and sprinkle the surface with charcoal dust when to be had. Attend to the earthing-up of *Celery*. Take advantage of a fine day to tie up *Endive* and *Lettuce* for blanching. Turn over and rope up *Onions* on wet days. Examine *Potatoes* and any other roots which are stored away.

FRUIT GARDEN.

Prepare ground for new plantations of Currants and Gooseberries. Cuttings of favourite sorts of Gooseberries may now be made, and planted in beds manured with leaf mould and sand; the latter will aid their rooting, and the former will hasten their growth.

FLOWER GARDEN.

When the unfavourable weather has taken effect on Lobelias, Salvia patens, and similar plants they should be taken up, especially where the flower stems are killed as well as the leaves. The Salvias, however, ought to be left in the ground until the stems die down, as the roots will be thereby much benefited. The best way of keeping these plants is to place them in pots merely sufficient to hold the roots, using rather dry soil, and set them where they will be dry and cool. A few degrees of frost will be less hurtful than heat; they must receive no water until they commence growing. Scarlet and other Pelargoniums for turning out in spring ought to receive the same treatment, only they cannot be too soon taken up after their beauty is once destroyed. Although the old Chinese Rose is very much neglected as compared with what it used to be, it is by no means unworthy of a place in pleasure grounds, even with all the attractions that newer sorts possess; the more it is cut the greater will be its profusion of flowers, and cuttings put in now in an open border, leaving one bud above the ground, will strike root readily. Borders or beds for bulbs should be well drained, and somewhat raised above the general surface with some good hotbed dung, fresh soil from an old pasture, and some sand. What dry surface heath soil is to Cape and New Holland plants, virgin soil, as it is called, is to bulbs of various kinds. Use such open-textured material as fern and straw for protecting tender Roses, as the air will be diffused throughout; it will not only keep the heat in and the cold out, but prevent that stagnation which moss and all such close materials invariably cause, particularly if much rain falls. Not a day should be lost, now the weather has become settled, in making up Pink beds. So much improvement has taken place lately amongst these flowers, that amateurs, unless they have added to their collections regularly, will find themselves apparently a century behindhand. Dahlias are still blooming in many places, but rather miserably. As soon as the tops are blackened by frost take them up, otherwise they are apt to start at the crown. Cut them off about a foot long, and place them in such a manner that the sap which exudes may not run into the hollow stem; should it do so decay will be the probable consequence. Small pieces of zinc or lead attached to copper wire are best to mark them with, or the zinc may be stamped with a number corresponding with the name in the book. Plant offsets of Tulips, and arrange the best bed definitely previous to planting when the soil is sufficiently dry; the sooner the better.

GREENHOUSE AND CONSERVATORY.

As the beauty of out-door plants gives way before the storms of autumn the conservatory should be made as attractive as possible, as it will now become in some respects the only place where flowering plants can be inspected with comfort in unfavourable weather. To assist this let the requisite arrangements both as regards watering and changing the plants take place early in the day, that the effects of the watering, syringing, &c., may be removed, and an agreeable dryness pervade the house, before it is visited by the family. No pains must likewise be spared to keep the house gay by introducing plants in succession as they come into bloom, including a portion of the stove plants which have been grown expressly for this purpose. A little gentle forcing will bring the different varieties of Epiphyllum truncatum into bloom; and with the addition of Chrysanthemums, late Fuchsias and Pelargoniums, Pancratiums, Amaryllids, Mignonette, Neapolitan Violets, &c., a tolerably gay appearance may be maintained until the time when forced plants will be more generally available. Let the admission of air be well regulated, so as to preserve a gentle circulation throughout the house in mild weather without causing draughts. Fires will be necessary, not so much for keeping up the temperature, except during frost, as for the purpose of promoting a medium state of dryness in the external air, so as to make the house enjoyable in all weathers. Some of the most useful plants for house decoration during winter and spring, when subjected to gentle forcing, are the different kinds of Rhododendrons, Azaleas, Kalmias, &c., usually termed American plants. As these have now perfected their buds, plants well furnished with buds can easily be selected for the purpose. Without naming each particular kind suitable, I may remark that many of the hybrid scarlet Rhododendrons which, owing to their earliness, rarely bloom in perfection out of doors, are the best for early forcing, coming into bloom with but little trouble. After selecting the plants from the nursery have them potted in peat in as small pots as the roots can be well placed in; they may then be watered and set in a pit or empty vinery to be brought forward as required, beginning very gently with them at first in a moist heat, and increasing the heat as they advance towards blooming. Pelargoniums should be placed rather near the glass, to preserve a short-jointed and sturdy habit of growth; all useless shoots should be thinned out, and the principal shoots pegged out at regular distances, so as to maintain a due balance of shape. Thorough cleanliness should be maintained at all times in respect to stages, glass, and floors. If these directions be attended to the spotted leaf will not show itself, neither will the plants require many sticks to assist them, but a healthy sturdiness will at all times be maintained. Now is a good time to cull out from the first-struck batch of herbaceous Calceolarias some of the best plants, and give them a liberal shift, using fibrous light loam, rubbly charcoal, and sharp clear sand intermixed. These plants, with due attention throughout the winter, will make large specimens, and produce a good show in the conservatory or mixed greenhouse. The Cinerarias intended to flower as specimens early in spring should now receive their final shift. If Mignonette to stand the winter has not yet been sown, sowing had better now be deferred till spring, when a little put in early will bloom nearly as soon as plants from seed sown now, and the difficulty of wintering it will thus be avoided.—W. KEANE.

DOINGS OF THE LAST WEEK.

SOMEWHAT unexpectedly we had a severe frost on the morning of the 19th, followed by mild weather. We were not unprepared, as for several nights the temperature was close on the freezing point, and accounts in the newspapers of snow storms in the north, and the north wind, ought to have made us additionally careful. If we had expected 8° below the freezing point on a north wall 5 feet from the ground, and nearly 10° on the ground level, we certainly would have protected Scarlet Runners, &c., more than we did. We covered Cauliflower in head not sufficiently protected early in the morning, and it has not suffered. The only crops injuriously affected were Kidney Beans and Scarlet Runners; and of Pelargoniums, some good plants of variegated Alma were softened to their base. Dahlias were blackened, and we were sorry for it, as the flowers were so useful; Heliotropes were also blackened in low-lying places, but in raised beds they were little injured. A few Scarlet Pelargoniums in raised beds are still rather bright, but, of course, with the exception of masses of scarlet Salvia fulgens, the glory of the flower garden is over for the season, though now most likely we shall let the beds remain a little longer, as a few plants look well with their green and variegated foliage. A fine line of Bijou Pelargoniums is still untouched, and many blooms

are now fully open after the bright sun of Thursday. The dull days of Friday and Saturday have made the beds look duller than they otherwise would do. A fact is here worth mentioning. Scarlet Pelargoniums close to our own door, protected with walls quite close to them, have suffered more than those in the open lawn, with a rather free exposure to the wind; and another fact is, that in these exposed beds the south side is the best, the very place where the sun would beat first on the frost-hardened foliage. On the north side of the beds the foliage is nearly as fine after the nipping, but the flower trusses are almost gone; on the south side many of the trusses of bloom are wonderfully full and bright. Much, no doubt, is owing to the comparative dryness of the soil, but the sunny side being the best after such a sunny morning, is not what is generally expected after a severe frost; but here in every case the south side is the best, which we can hardly account for in connection with previous conclusions founded on observation. Calceolarias, though stiff, soon recovered. In the afternoon following the frost we took off a great many cuttings, and placed them under cover, fearing we might have a repetition, but the wind changed, and we had mildness instead of frost, and now we can go to the plants and take off thousands of fine cuttings that do not show a trace of the frosty night.

KITCHEN GARDEN.

Celery.—We do not usually earth-up our late Celery until the end of the month; but as the sun has now little power in causing the Celery to evaporate moisture, and as the frost might injure it a little, we gave a little earthing-up to the whole, except the last planted, and as we were anxious to keep it clean, we used a little sifted coal ashes and cool burned earth and ashes round the plants by means previously adverted to, and then pressed the well-pulverised earth close to the ashes. This is more necessary in our somewhat stiff soil, and especially when the Celery is grown in beds, as we generally do, from three to five plants across—a plan that on the whole saves much space and labour. If we had plenty of litter, as stubble, &c., we would never earth-up too high as respects late Celery, but pack up with material of this kind, as it blanches the plants very well, keeps the frost out, and if rounded over a bed, when once the surface is flattened and crusted, it throws off the heaviest rains. We have several times recommended highly, and not in the least too highly, the Dwarf Incomparable White, but a red sort sent to us for trial by Mr. Welch, of the Palace Gardens, Armagh, has also proved remarkably good, blanching more quickly than reds generally do, being very firm and sweet, and as yet less marked on the outsides by enemies than the white is. We shall be glad to find it stands wet and frost well; at present it seems a good variety.

Mushrooms.—We have spawned and earthed-up two pieces in our Mushroom house, shallow beds on shelves. We should like one to show its produce in about a month, having as yet a good supply in the outside sheds, as lately adverted to; but though the first of these pieces in the house kept all right as tested by the trial-stick, we find within a few days that the bed has become colder to the hand than it ought to be with the spawn working freely, which always produces a little heat of itself; and as we did not find it convenient to cover the bed, nor to heat the house at present, we put a dozen barrowloads of droppings, &c., on the space beneath. This will soon make the bed as hot as we wish it to be, and bring in the Mushrooms as early as we want them. We attribute the bed's becoming a little too cold to the mixing rather too much fibrous loam with the dung; but the dung was rather open and rough, and we used the loam to make it firmer, and to prevent its heating so violently as it would otherwise have done, as the more violently the manure is heated, the more will its nourishing properties be driven off. In our sheds more covering was placed on the beds after the frost. A Mushroom house is very useful, and for other purposes besides Mushrooms, but simple plans answer as well as the more complex and elaborate; and after trying many modes, and being successful with them all, at least fairly so, we must say we never had better Mushrooms than on ridges out of doors. Of course in winter they had to be kept warm by covering, and in summer they had to be kept cool by covering, and having that covering rather damp, instead of dry as in winter; but then there was considerable labour in covering and uncovering, much more than where there was the advantage of a house or even a shed roof to keep snow and rain from the beds.

Cauliflower.—The young plants pricked out in squares for hand-lights had the bottoms of the hand-lights put over them, and as they were in bad order the holes were filled-up with slates and tiles firmly fixed against them. In severe nights a few evergreen twigs will be laid across. The tops that seemed as if they had been riddled by shot must lay aside until we have a wet day to clean and reglaze them. A wet day is our busiest day; there is no want of in-door work for such days. We must try and prick out a frameful of plants, and place others in a sheltered position. We have succeeded well with plants placed singly in small pots, and repotted and planted-out in finely-pulverised soil in March and April, but generally we have done as well with plants pricked-out 3 or 4 inches apart and lifted with balls. In pricking-out, though the soil be pretty rich, the plants will do better and be saved from many enemies, if they have a surfacing of rough sand on the ground.

Cucumber Beds.—These require banking-up to keep them on. We rather reluctantly pulled the plants out of a two-light box, as we wanted the space for another purpose. We mention this, however, chiefly on account of a certain fact—namely, that there was a fine moist bottom heat in that bed, though it had not been touched since it was made up in March, and then, be it remarked, it was made up chiefly of green dung as it came from the stables, suitably moistened and mingled so as to keep up a long, gradual fermentation, and the bed was then surfaced with older sweet dung and tree leaves. The surfacing and the soil kept down all deleterious vapours, whilst the heat was allowed full play to rise, which it has done regularly all these months. We have seen manure turned and sweetened to such a degree, and built so firmly together, that not a breath of air could penetrate into it to support decomposition, and thus after a violent heat the flame, as it were, expired, either because there was nothing to burn, or no air could reach the material to make it burn, and it went out like a candle under an extinguisher. The making of a hotbed to last, as practised by some of our old gardeners, who looked on so many turnings and sweetenings as so much waste labour, is pretty well lost amid the improved systems of heating. Nevertheless, let it be borne in mind, that old dung hotbeds are not the worst means of securing those results which prevent even cooks having the chance to grumble. We know cases where there is abundance of fire and water, but a little dung can scarcely be had for producing fine, close, crisp Cauliflowers.

FRUIT GARDEN.

We had gathered almost all our fruit before the frost, as a few nights had been so close to, and even below the freezing-point. The leaves of the trees were rather green and flourishing for the season. Never did one night produce such a change as was effected on many trees. The crisp green leaves on one evening were brown before the next, looking as if a scorching fire had been placed beneath each tree. The men said the leaves looked as if they had been burned, and resembled the foliage of some Chestnut trees, which, being near the ground, were affected by the heat from our burning and charring heaps of rubbish. The dry heat from the fire and the dry air from the frost had acted much the same—namely, deprived the foliage of its moisture. Some time ago, when treating on ventilation in winter, and venturing on the remark, that allowing great blasts of cold frosty air to enter a hothouse would have nearly the same effect on tender plants as sending among them dry, very hot air from a furnace, we had several letters sent to us, the purport of which was to tell us we had taken leave of our senses. "Why, you might as well tell us that a tropical sun and an arctic winter would in any case produce similar results." Well, our best answer is to refer to the appearance of many hardy fruit trees on the morning of the frost. The man who noticed such a marked parching-up effect from frost, and then admitted cold frosty air freely among tender plants, has profited but little by the faculties of observation with which he has been endowed. It is pleasant to note the proofs of progress about us; but that progress would be all the more certain if our younger gardeners, the hope of the future, and in some respects the stay of the present, would not be above the habit of attending to little things and little facts, and from these drawing practical inferences. The shrivelling up of a green leaf by a trifling frost, making it like a piece of half-burnt linen, may well give a lesson that though fresh air is desirable, the air, if dry and cold, should not come in contact with a tender plant in a house before being considerably moistened and warmed.

Peach House.—Wanting room to house numbers of bedding plants for a few months, we have had the glass of this house washed with soap and water, all the remaining leaves removed, and the trees and woodwork well syringed with soap water as warm as it could be applied, using a cloth on the syringe to

protect the hand. Of course, if such water was at a temperature of 200°, it would not be above 160° or 170° by the time it reached the trees, and few eggs of insects will resist that heat. Of all cleansers we prefer warm water. The soap is also a help, and we prefer soft soap, say a common table-spoonful to five gallons of water. After thus syringing the woodwork of the trellis, &c., the wood of the trees was washed with similar water, employing large soft-hair brushes for the purpose; but as the hand had to be used beneath the twigs, the water would not be warmer than 125° or 130°. The displacing of insects' eggs under such circumstances will generally settle them. Then the woodwork of the trellis was coated with quicklime paint, so as to make that all secure. We would much approve of a wire trellis, but, though we have waited for it for years, there the wood is, and we must prevent its being a harbour for insects' eggs. As a farther security we painted the trees all over with a soft brush, and a paint formed of a little soft soap and sulphur, with a good bulk of clay. Without saying a word against Gishurst or the many other paints used, we are almost of opinion that good clay paint of itself is very nearly as good as the best of them. A little soft soap in the water used causes it to adhere all the better. The chief object of all such painting is to smother up all insect eggs if there be any, and cause them to perish from want of air, and nothing does this better than clay. As the buds begin to expand the clay begins to crack, and if it seems to hold them rather tightly a slight dewing from the syringe makes it soft. There is no danger of an overdose, as may soon be the case with some of the other compositions. Sulphur is generally an ingredient in all such preparations, but in its simple state we know of no case in which sulphur is injurious to insects. The fumes of sulphur will drive off, if not kill, the red spider, but amongst sulphur itself we have seen the spiders disporting themselves as so many sand boys.

In this house we had scarcely an insect last season, except a few green fly on Strawberries; but it is well to err on the safe side, as though most of the aphides and other insect enemies are viviparous during summer, the first invading army in the spring generally comes from hosts of eggs that have remained in a state of dormancy in winter. The surface soil was likewise scraped off, and some warm water applied over the new surface with a rose. A little flowers of sulphur may be dusted over the ground, if the trees show any sign of mildew on their tops or roots. These processes may well be gone through even as matters of precaution. We have only done this as yet with the bulk of the house, so as to cover the floor with boxes of plants; the trees on the back wall will likely remain unwashed, except for the syringing referred to, until we have a wet day. Much of the general economy of managing a garden will ever consist in the right timing of labour. Prevention in the case of insect attacks is even better than any mode of getting rid of them. We have been perfectly astonished at seeing the bills for tobacco and other killing agents used in some gardens. Better, if possible, prevent insects appearing.

ORNAMENTAL DEPARTMENT.

The clearing of our Peach house, except the back wall, and covering the floor with boxes of bedding plants beneath the trellis, and the front shelves, &c., with the same, gave us a cold pit at liberty for *Calceolaria cuttings*. This pit is too deep for our purpose, and sometimes we put fresh earth on the surface of what is left, and plant the cuttings in it. We prefer, however, doing all afresh, and so as to have a rather open instead of a close, firm bottom. We therefore take out the soil and the little rotten dung and leaf mould, place, say one large or two small barrowloads of dry litter in the bottom of each light, tread it firm, follow with 2 or 3 inches of half-rotten dung, and then with an inch of roughish sweet leaf mould, mixed with riddlings of fibrous loam, and well tread again. Next follows a layer of 2 inches of fresh fibrous sandy loam, with just a very little leaf mould and black dust from our charring heap; then we tread, level, and surface with a quarter of an inch of road sand collected in hollows after floods. In this the cuttings are inserted in rows, from 2 to 2½ inches apart, and from 1 to 1½ inch apart in the row. Sometimes there are a few failures. Last season not one cutting in two thousand failed to strike. The cuttings are firmed, and when a light is done the soil is well watered through a fine rose. Frequently before watering a little fine sand is strewed by hand along the rows, which fills up all the holes, and causes the cuttings to be very firm. This season the cuttings are rather too large, and require either to be topped or the leaves much reduced. We greatly prefer short, stubby side shoots, taken off with a heel close to the old stem, the cuttings averaging 2½ inches in length. These were clean cut at the heel, two or three of the bottom leaves removed, the top ones, if large, shortened, but the young leaves in the centre of the growing point left untouched. After the first watering the cuttings will need no more for a long time, except a gentle dewing on a sunny day, a little shading when the sun is powerful, and the sashes shut down then, but a little air given at the back night, afternoon, and morning in mild weather, shutting up closely only when frosty. These Calceolarias will be early enough if they begin to strike root about the New Year, and then we place them in earth pits in the middle of March to give them room to grow strong and bushy, so as to lift with balls in May. Last season, from inserting the cuttings until about finishing blooming, the Calceolarias were never visited by an insect. Coddling and fire-heated places have spoiled thousands of Calceolarias.

Centaurea candidissima and Verbenas.—The Cucumber bed referred to, and one of a similar kind, after being fresh turned up for a foot or two, a little fresh material added at the bottom, and a layer of dry ashes at the top, was devoted to the purpose of giving a little encouragement to cuttings of the above. We stated last season how old plants of Centaurea can be treated successfully, but old plants, except for a few centres, are comparatively useless, as the smallest plants in spring will soon be large enough in summer when planted out of doors. The smallest hits strike easily in heat in spring. It requires larger pieces to strike well in cold pits in summer and autumn. There is no difficulty in raising a fine stock from cuttings inserted at the end of July and the beginning of August; but we could not take off ours so soon, and we thought we would prefer a lot of young plants to the old ones, as taking up less room. What we put in by the beginning of September are well struck. What were inserted from the middle to the end of that month in pots in a cold pit, though all sound, are merely callusing, only a few beginning to root. These, if we could have spared the room, we would have inserted each at the side of a small pot, as the roots are so brittle. We have adopted the next best course—namely, placed two cuttings in a 3 inch pot, with a piece of slate or tile down the centre of each pot, so that the roots will not much intermingle. These, with the soil sufficiently moist, we have moved to the gentle hotbed, surfaced with dry ashes, and in them plunged the pots. In from a fortnight to three weeks we expect every pot to be filled with roots, when the pots can be set anywhere under protection, as it takes a considerable degree of frost to injure the plants. Damp is a greater enemy. To some Verbenas which were rather late, we have given a similar help. Tender kinds of Pelargoniums have been taken up and repotted; the bulk are still uninjured.—R. F.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Select List of New and Choice Pelargoniums, Auriculas, Carnations, Picotees, &c.—Catalogue of Roses, Fruit Trees, Coniferæ, Hardy Trees, Shrubs, Climbing Plants, &c.*

G. Jackman & Son, Woking Nursery, Woking, Surrey.—*Catalogue of Plants.*

COVENT GARDEN MARKET.—October 27.

A slight improvement in business has enabled us to reduce our stocks, but without any advance in price, the great bulk of fruit being of only second-rate quality, and having evidently been much injured during the late storms. Some consignments of Chaumontels from the Channel Islands have come to hand this week, but they are not fine. Vegetables are abundant and excellent.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Camellias (*W. G. C.*).—All those you mention are in the catalogues of Messrs. Veitch, Williams, Rollisson, and others.

Rockwork at Oak Lodge (*P.*).—We are informed it was constructed by Mr. Pulham, Terra Cotta Works, Broxbourne.

Seedling Pelargonium (*Peter*).—Your seedling Polargonium is very pretty, but not distinct enough from many varieties that have been raised from Mrs. Pollock to make it of any value as a new variety.

Pansies for Breeding (*Idem*).—For the darkest Pansy, Ladyburn Beauty: and the other best six Pansies for saving seed from we consider to be Comus, fine yellow; Mary Russell, fine white; Alexander Tait, fine dark self; Imperial Prince, purple self; Mr. J. Ingram, dark plum; and Alice Downie, light cream.

Pinus for Clay Soil (*Stikes*).—We think your soil needs draining. Pinus austriaca succeeds where many others fail, but if your ground were drained, there are few of the Pine and Fir tribe that would not succeed. There is no evergreen tree that would suit you.

Tricyrtis hirta not Flowering (*Tweedside*).—We can only account for the plant not flowering from its being grown in too cool a place, and in heavy soil. It likes an open but sheltered situation, and a rich fibrous loam, with a free admixture of sand or gravel, and good drainage. It is a fine herbaceous plant but recently introduced from Japan, with large branching corymbs of starry flowers, often more than 2 inches across. The flowers are finely spotted with purple.

Seedling Ipomœa (*Old Subscriber*).—Do not cut the plant down now, but keep it dry during the winter, and prune it in spring, only thinning out the shoots. It will probably flower next year. The best compost is two-thirds sandy fibrous loam and one-third leaf soil, or sandy fibrous peat, with a free admixture of sharp sand. Good drainage is necessary. Keep the plant near the glass, and give it abundance of air.

Cucumber Leaves Diseased (*Idem*).—We do not notice anything the matter with the leaves, except that they appear to have been attacked by red spider, though there was none on the leaves sent us. Heat the pipes to a temperature of 160°, and paint them with sulphur, keeping the house close: The sulphur should be mixed with a solution of 4 ozs. of soft soap to a gallon of water. The soft soap will make it adhere longer and better to the pipes. Keep a moister atmosphere, and supply the roots copiously with water.

Magnolia for West Wall (*K. W.*).—The Exmouth variety of M. grandiflora is the best on account of its free-blooming habit. No climber would succeed on an east wall on which the sun never shines; but Roegner's Ivy is one of the best.

Thorn and Holly Berries (*I. I. D.*).—The berries of the Holly and haws of the Thorn need not be buried unless you like. You may keep them until next February and then sow them, but they will not grow until the following spring. The advantages of burying them for a year are, that they occupy but little room, and the ground they would require if sown when they are gathered may be used for a more advantageous crop. The berries ought not to be gathered until they are quite red, and they should be laid in a heap for a few weeks, and pitted, say in December. They should remain in the pit for twelve months, and then be spread out rather thinly to dry. In February or March they should be sown. To pit them now and sow in spring would only be labour in vain, as few, if any, plants would appear next year, only you might take a crop off the ground next year, and sow the haws and berries the following year.

Potato Onions not Keeping (*A. H.*).—The Onions were no doubt grub-eaten before you took them up, and the decay is only a consequence. Shallots very often do the same. We know of no remedy; but a good dressing of lime and soot to the ground before planting, and blackening the soil with charcoal or wood ashes, neatly pointing them in before planting, will in most cases prevent the attacks of insects. The Onions ought to be pulled up as soon as the tops begin to turn yellow, and be well dried in the sun before storing them.

Painting Hot-water Pipes (*A Constant Subscriber*).—Nothing is better than lampblack brought to the consistency of thin paint with linseed oil and turpentine, one-third of the latter to two-thirds oil.

Manure (*H.*).—If you can obtain good stable manure for 5s. per load, you will find no fertiliser cheaper. Some artificial manures, and sewage would aid you. Read "Manures for the Many;" you can have it by post from our office, if you enclose four postage stamps with your address.

Tank-heating Pits (*F. W. G.*).—We think you can do all you desire with your tanks in the pit, and as you propose. Load will do well enough for the connecting pipes from the boiler if they do not come in contact with the fire. If they do, you had better have iron for a foot or two in length. We would prefer zinc to block tin for the tanks, and we should prefer them at least 3 inches in depth instead of 2 inches, as, though deep tanks are mere waste, it is possible to have them too shallow. Will not five divisions in a brick pit of 20 feet in length take up a little too much of the space, unless, indeed, you have thin wooden or tin divisions, to move at your pleasure? We often use a thin wooden movable division, made to slope like the rafter. We hardly know what a pit of this kind would cost, as we know nothing of its size except its length, but a bricklayer will easily tell you from its size, and then you must consult an ironmonger. We do not think block tin would last any considerable length of time.

Marvel of Peru in a Bed (*Lycia*).—The Marvel of Peru, after being raised and its tubers formed, may be treated much the same as Dahlias. They might be long bloomers in a greenhouse, but the first frost kills them. They are poor compared with the Gladiolus. Why not combine them—plant the Gladiolus in rows and the Marvel of Peru between them? and as the Gladiolus flowers begin to fade the Marvel of Peru would come in. The Gladiolus succeeds well in Rhododendron beds. We have had some fine rows, near which Salvia fulgens was planted, and as the Gladiolus went off the Salvia formed a scarlet hedge.

Turf Pits (*H. V.*).—We much approve of having your pits above the ground level. Why have two turf pits, 4 feet by 5, against a wall? Would it not be better to do away with the division, and thus save space? We think the paraffin lamps would do all you require, with the help of a mat over the glass in a severe night. We hardly know what you mean by a stove placed outside and the chimney running through the back of the pit. If an iron stove, it will not do, as a long horizontal pipe never answers. If a furnace sunk below the level, it would answer, be the pipe or flue what it might, and if your pit were from 20 to 30 feet long, we would recommend it.

Half Sieve and Sieve Measures (*W. Thompson*).—The following is the statement in Hogg's Gardeners' Year Book. *Half Sieve.*—Contains three and a half imperial gallons. It averages 12½ inches in diameter, and 5 inches in depth. *Sieve.*—Contains seven imperial gallons. Diameter 15 inches, depth 8 inches. A sieve of Peas is equal to one bushel; a sieve of Currants twenty quarts. *Bushel Sieve.*—Ten and a half imperial gallons. Diameter at top 17¾ inches, at bottom 17 inches; depth 11¼ inches. *Bushel Basket.*—Ought, when heaped, to contain an imperial bushel. Diameter at bottom 10 inches, at top 14½ inches; depth 17 inches. Walnuts, Nuts, Apples, and Potatoes are sold by this measure. A bushel of the last-named cleansed, weighs 56 lbs., but 4 lbs. additional are allowed if they are not washed. A junk contains two-thirds of a bushel.

Arrangement of a Circular Bed (*Flora*).—We ourselves do not like the white Cerastium to be backed by the yellow Calceolaria; a compact blue Lobelia would be better. If you could manage four beds we would plant as now, but with the Lobelia between the Calceolaria Aures floribunda and the Cerastium; for instance, Scarlet Pelargonium, Aurea floribunda Calceolaria, Lobelia, and Cerastium. If you can only have three, have the Lobelia next the walk. Nothing, however, is better than the Cerastium when well kept and regular. It is a good system also to change your cropping. You might, therefore, have Amantia multiflora Calceolaria for the back circle, Little David Pelargonium for the second, and Cerastium for the third. If you could have a fourth, have Purple Verbena between the Pelargonium and Cerastium.

Potted Vine in a Greenhouse (*C. E. W. C.*).—You will succeed best with your Black Hamburgh Vine in a greenhouse by setting your plant in the pot in the house from the beginning of March or the end of February, and allowing the Vine to break naturally with the general temperature of the house. You ask the size of the pot to be used, soil, &c. The Vine will fruit best in the pot in which it has grown this summer, but if it is in a pot less than 15 inches in diameter, you might shift it into that size now, ramming the soil rather hard, and then plunge the pot over the rim in litter, so as to give it for a time a temperature at the roots of from 50° to 60°, leaving the head of the Vine exposed. Fibrous loam, with some bits of broken boiled bones, will be the best soil. If the pot is of the size stated above, merely remove carefully an inch or more of the surface, and replace it with rich fresh compost.

Vines for a Cool House (*A Ten-years Subscriber*).—The house you are about to put up against your garden wall may be taken down at the expiration of your lease if the plates are not fastened to the foundation, nor to the walls. For fruit trees to succeed on the wall, the Vines ought not to be planted more closely together than 4 feet, and for the trees to succeed well after the Vines reach the top of the house, the Vines should be 6 feet apart, which is the distance we recommend when trees on the back wall are expected to fruit. If your object be Grapes, and you do not much care what is grown on the back wall, you may have the Vines 3 feet 6 inches or 4 feet apart, and occupy the back wall with Figs, which thrive exceedingly well with the Vines. In this case you will have twenty-four Vines, and eight Figs on the wall. What we, however, advise is, if you wish for more kinds of fruit trees than Grapes and Figs, is to plant the Vines 6 feet apart, and have Peach and Nectarine trees on the back wall, with a few Apricot, Plum, and Fig trees in pots on the front border. The most suitable *Vines* are, one Early Saumur Frontignan, two Chasselas Vibert, three Foster's White Seedling, two Buckland Sweetwater, two Trentham Black, four Black Hamburgh, one Black Champion, one Espiran. *Peaches:* one Early York, two Grosse Mignonne, one Galande. *Nectarines:* one Elruge, one Rivers's White. In pots on the border, but not shading the trees on the back wall—*Apricots:* two Oullins Early Peach, two Peach or Grosse Pêche, two Moorpark, two Kaisha. *Plums:* two July Green Gage, four Green Gage, four Jefferson's, one Golden Esperen, four Coe's Golden Drop, one Transparent Gage. *Figs:* two Early Violet, three Brown Turkey, and three White Marseilles. If you have the Vines and Figs only, the varieties last named will be suitable for the back wall in place of the Peach trees.

Vine Border (*West Cumberland*).—Your inside border having no communication with an outside border will grow Vines perfectly well if you be careful to keep them duly watered. Keane's two little volumes "Indoor Gardening" and "Out-door Gardening" will suit you. They can be had by post from our office if you enclose forty postage stamps with your direction.

Pruning Young Vines (*J. H.*).—We would leave for next year the most

of the 1½ foot of good wood made. Add a little lime rubbish and a few broken bones to the soil, and mulch the roots with rotten dung. See ground vinery, page 312, of our No. 446.

Vines in an Unheated Peach House (*New Forest*).—In such a house four Vines will do very well, and be no great injury to the Peaches. We do the same, still the Peaches would be better without any shade except what we choose to give. Where both are grown a compromise must be made.

Grapes Small and Seedless (*J. C. M.*).—We have no doubt, that not want of room for the roots, but their going down into the dry, sandy, rocky soil, and more especially after such a season as last year, is the chief cause of the berries of the Vines being seedless, refusing to swell, and shanking-off as they are now doing. The mulching and the watering were all right enough, though under the circumstances coming too late, and when the waterings and rains penetrated to the dry roots, the sudden excitement and the free flow of sap were too much for some of the berries, and they cracked in consequence. A 12-feet-wide border is a fair size for an ordinary house, but one 18 feet wide would be better. The walk, if important, might remain where it is, with good soil beneath a shallow layer of gravel. Adding fresh soil to the extremities would also be useful, and in such a steep border as a 4-feet fall in 12 feet in width, mulching and watering at the surface so as to encourage the roots upwards, would be a matter of importance. We can well understand how the Grapes would shank and shrivel, though the wood and the leaves seem so healthy. This is often the case when the roots go deep in search of moisture, and you state the most and best of your roots are 2 feet from the surface. If you come to the conclusion that this season's growth is an exceptional one, owing to dryness at the roots and the singular summer of last year and partly of this, then we would be satisfied with removing a part of the surface soil, and adding fresh, mulching and covering with litter in winter and spring, to encourage the roots to come nearer the surface. But for the hope that this treatment would be successful for the next season, we would at once set about a radical remedy, and carefully lift and replant the Vine roots, placing them about 6 inches from the surface, and afterwards keeping the surface mulched in summer, and protected with litter in winter. See "Doings of Last Week," page 327.

Gros Guillaume Grape (*A Subscriber*).—It is usually called Barbarossa. Any nurseryman could supply you. There never has been a yellow Cabbage Rose.

Raising Vines from Eyes without Glass (*Amateur*).—In the absence of glass your only plan will be to insert the eyes about 3 inches from a south wall, in good, rich, sandy soil, covering with an inch of fine soil. They should be inserted in March or April; or when the Vines are pruned the eyes may be put in, as they will remain dormant until the soil becomes warmed to a temperature of 50° by the sun's rays. For out-door culture cuttings are a more certain mode of propagation. Two joints are sufficient, covering the uppermost eye an inch or so with soil. They should be inserted at the foot of a south wall, or in a warm situation, and in sandy soil. You will find a receipt for Tomato jam at page 270 of the present volume.

Peach, Apricot, and Plum Stones (*Idem*).—They may be sown now, or kept in a cool place until next March if covered with 1 inch of soil. A sandy soil and a sheltered situation are most suitable.

Grizzly Frontignan in Cold Vinery (*C. R.*).—We do not think you will succeed with the Grizzly Frontignan Grape in an unheated house. We do not see why the Victoria Nectarine should not succeed against the back wall of an orchard house facing the south.

Peaches and Nectarines as Cordons (*Idem*).—We have no doubt that they could be so grown in ground vineries, whether of Rendle's or the older plan. Of course, double or triple cordons would depend on the width of the little house. We like everything new; but had we a wall at liberty, we would sooner place glass against it than be troubled with huge moveable glasses. Remember, however, we like to see these ground vineries; but cheap as they are, we think them dear enough.—R. F.

Asparagus Planting (*Asparagus*).—We recommend you to leave the plants as they are until next May; they will then be growing. Take all up and plant, watering well in dry weather. Two rows are sufficient for the beds 27 inches wide, and allow 15 inches between the rows and 12 inches from plant to plant. We presume you have alleys 2 feet wide between the beds. The width of the beds is immaterial if they do not exceed 5 feet. We prefer 4-feet beds, three rows in a bed, and the plants 1 foot apart in the rows.

Vines for a Cool Greenhouse (*Centurion*).—The six Vines most likely to suit you are—one Muscat of Alexandria, at the end where the flue comes in; one Muscat Hamburgh, one White Frontignan, one Black Frontignan, one Muscat St. Laurent, and one Chasselas Musqué. But even these will not ripen well unless, when in bloom and afterwards, you give less air than would suit the generality of greenhouse plants

Grafting Vines (*R. U.*).—The colour of the berries being different does not interfere with the grafting. Vines bearing black Grapes may be worked upon Vines bearing white Grapes, and *vice versâ*.

Vines in a Conservatory (*A Constant Reader*).—Vines are often grown in conservatories, and they are very handsome; besides, the Grapes would pay you better than anything else. You would derive more profit from them than from growing plants, and selling seeds, cuttings, and plants, which are not easily disposed of by private individuals. It requires a connection to do so profitably.

Seed Potatoes—Potato for Heavy Soil (*Idem*).—A seedsman would no doubt take your Potatoes if of a good sort, true, and a good sample; or you may dispose of them readily enough in any market. Milky White is a good second early, and Webb's Imperial a good variety for the general crop, both kidney-shaped; and for winter or general crop Paterson's Victoria.

Planting Fruit Trees (*Idem*).—The best time to plant fruit trees of all kinds is as soon in autumn as the leaves have fallen, or are partially fallen, or even from November to the middle of December during mild weather.

Gardenia florida not Flowering (*G. H.*).—We attribute the falling of the flower buds to the potting, and the check consequent on the removal from the hotbed. When swelling their buds, the plants are all the better of a slightly increased temperature, and even gentle bottom heat, continuing it until the wood is formed; then by a drier atmosphere, and plenty of air and light, insure the wood being well ripened. A temperature of from 45° to 50° is sufficient when the plants are not growing. They are spoiled by too much heat.

Sowing Solanum capsicastrum (*Idem*).—You will gain very little by sowing the seed now, though you may do so; and grow the seedlings in a stove during the winter, potting them off, when large enough, in small pots, shifting them into larger as required, hardening-off, and removing to a greenhouse in May.

Gloxinia Propagation (*Idem*).—The plants may be started in January, and when the leaves are large enough insert them, and when they are well rooted and good tubers have been formed, dry these off, and rest them for six weeks or two months; you may then start them, potting off after they have shoots about an inch high. They will make good plants by autumn; but it is better to let them rest longer. It is very likely some of the tubers will not push vigorously until late in autumn. The plants may be continued in heat, and they will grow without rest, but we do not approve of the practice. Eucodonia and Plectopoma may be treated like the Achimenes, to which they belong.

Roses, Cécile de Chabrillant, Mesdames Rivers and Vidot (*Q. Q.*).—"I am not surprised at questions about their culture, nor is 'Steevie,' my man. I read to him the query, and he said, 'they are three ticklish jokers.' If they are standards, take them up and clump them for the winter in a sheltered place, and place a little straw over the roots and round the stems in severe weather, and plant them out again during open weather in February. If they are ground plants the same may be practised. The fact is, they are more subject to fungoid diseases, and more beloved by aphides than many other sorts. Their lungs being injured by the above, or by violent winds destroying the foliage whilst sap is active, the health of the plant suffers, and the skins which should be a healthy green become of a sickly yellowish green, or speckled. When ground plants of Roses of any kind are thus totally affected, it is best to cut them down in spring, and not depend upon the wood of last year. I cut down, as an experiment, twelve sickly Chabrillants last spring, and it answered well. I have bought eighteen Madame Rivers in dormant bud, to see if pre-establishment will do good. The above three Roses, W. Griffiths, and Madame Guinnoiseau—a Rose that should not have been given up, are a quintet of beauty and perfect formation. Mr. Rivers alone retains Madame Guinnoiseau.—W. F. Radclyffe."

Clematis not Flowering (*Poplar*).—From your description of the growth, we should say your plant is of one of the freer-growing sorts, probably Clematis Vitalba, or Traveller's Joy. If so, from its very free growth it does not flower until it has attained a considerable age, and we would not interfere with it beyond thinning-out the shoots. Train them in at their full length, so as to cover every part of the wall. If you wish for flowers rather than growth, you may now dig a trench about 2 feet from the stem, and deep enough to reach all the roots. Cut off all towards the stem which go directly down, leaving those in the ball undisturbed. You may then fill in the trench with rather poor sandy soil, and this will so check growth as to cause the production of flowers, probably next year.

Names of Fruits (*S. J. H.*).—Your Apple is probably the Wyken Pippin. (*W. O.*).—*Pear:* Belle et Bonne, a second-rate dessert sort; *Apple:* Rymer. (*W. S.*).—Yours are a very difficult lot. We give some names which correspond somewhat in general character and appearance to your fruit. We are, however, by no means certain of them:—1, Winter Colman; 3, Blenheim Pippin; 4, Dredge's Beauty of Wilts; 5, London, or Five-crowned Pippin. We have many other parcels of fruits which we will notice next week. Absence from home has prevented our examining them.

Names of Plants (*G. R.*).—Ceanothus azureus.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending October 26th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.			
Wed... 20	30.121	30.028	51	36	45	50	N.W.	.00	Fine and frosty; very fine; overcast at night.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE PROPOSED LONDON POULTRY SHOW.

It is with great regret we have to announce the impossibility of holding an exhibition of poultry and Rabbits during December of this year. Everything was going on satisfactorily, the Committee had met with liberal support towards prizes and the guarantee fund, and it seemed as though the arrangement would end successfully. The show was to have been held at the Corinthian Bazaar, if the proprietor would accept the sum he first proposed to the Committee—viz, £100 for the week, and £7 10s. per day for gas. On going to make a final settlement, he stated a more favourable offer had been made to him; he therefore did not feel disposed to keep open the place till required for the show, unless an additional sum were given in the form of royalty. The Committee were even prepared to accept this further charge rather than have no show; but he stated he could not give an answer till Monday, 25th inst. Supposing the answer to be favourable, there would only be six weeks to settle everything, and make all arrangements. This was considered far too short a time to carry the show properly out. Every endeavour was made to find a suitable place, but without success. On Tuesday the Committee had an interview with Mr. Wilkinson at the Crystal Palace, and that gentleman kindly promised to bring the matter before the Directors at their meeting on Friday. Sums already paid towards the guarantee fund will be returned by Mr. Crook.

The Committee have met with great encouragement from exhibitors and others; should they not be able to hold an exhibition during the next six months, they will endeavour to do so during the time of the Cattle Show in 1870.

AUCTION AT THE BIRMINGHAM POULTRY EXHIBITION.

I QUITE indorse Mr. R. B. Wood's suggestion that the sale of poultry should be postponed until Monday afternoon or Tuesday morning, so that it would give those who reside at a distance a chance of purchasing. I know several clergymen and gentlemen who would annually go to the Birmingham Show if they could attend the sale without losing Sunday at home, and I feel sure it would be a great benefit to the funds to have the sale convenient to all.—SAMUEL MATTHEW, *Stourmarket*.

[We have several more communications on the subject, which we will publish next week. Surely the Committee can alter the day as is wished.—EDS.]

PIGEONS' EGGS UNFERTILE—WING DISEASE.

I HAVE about eighty pairs of breeding Pigeons, and in August nearly every egg laid was bad. I was very much surprised at this, as previously I rarely had a bad egg, and I am unable to account for the circumstance. I thought the cause must be the weather or the birds going into moult, for since that time the eggs have been good, though in a few instances the second pair of eggs have also been bad.

I have had several birds taken with the wing disease. I always reckon in moulting time to have a few Pigeons affected with this disease, and I can generally notice when it is about to attack a Pigeon. The course I pursue is to catch the bird, and dress it under each wing with a small quantity of unction or sheep ointment; I then pluck a few feathers from the tail and other parts, so as to enable the bird to go on moulting. I am certain that the cause of the wing disease is the bird not being able to throw out its feathers, from weakness or some other cause. With but one exception the birds I have treated as above have regained the use of their wings. The only one which has not done so is a Yellow Beard cock, though by the treatment named I expect to restore it to health. It may be known when a Pigeon is about to be attacked with the wing disease, for if the bird is closely watched it will be seen that its wings tremble very much when it is about to fly. If the birds are caught and treated as described, they will, with few exceptions, recover the use of the wing affected.—W. WOODHOUSE.

[We commend our correspondent's letter to his brother Pigeon-fanciers. Bad eggs may arise from the birds not being able to procure enough calcareous matter, or from inflammation of the egg-passage—either, therefore, from accidentally not finding old mortar, &c., or from illness. We should be inclined to think it a temporary illness. In regard to wing disease, we think Mr. Woodhouse's remedy exceedingly sensible. The sheep ointment is mercurial; dressing the wing with tincture of iodine, which absorbs the liquid deposit, is also a good plan. Another correspondent, "E. S. B.," states that he followed the advice in the Journal, given, we apprehend, by "A FOREIGNER" at page 83, vol. xv.—viz, plucking the wing feathers, but as yet there is no cure made. We recommend the application of the iodine, and change of food, with a little aperient medicine; for, except in cases of accident, the outward trouble arises from internal derangement.—EDS.]

NORTH ORMESBY ORNITHOLOGICAL SHOW.

THE third annual Exhibition of the above was held in the schoolroom, North Ormesby, on Saturday, the 23rd inst., and was a decided success, both with regard to number of entries and quality of specimens shown, as well as visitors. The entries were fully one-fourth in excess of last year, sufficiently attesting the increasing interest attaching to the breeding and exhibiting of the chief of our feathered household pets, the Canary; and the growing confidence exhibitors from a distance feel in entrusting their birds to the care of the Committee of a well-managed Show.

In Belgians the entry was small, but the quality in both Yellow and Buff very fair, the first and second prize in the Yellows being won by Mr. R. Robinson, Middle borough, and Mr. W. Bulmer, Stockton; and in the Buffs by Mr. J. N. Harrison, Derby, and Mr. R. Robinson. The Norwich were really superb, and the highest-coloured birds took the prizes. Messrs. Irons & Gayton, Northampton, first; and Messrs. Moore & Wynn, Northampton, second in the Clear Jonques, the south-country breeders bringing out their birds in perfect condition. Messrs. Irons & Gayton were first again in Clear Buffs, with a wonderful bird; and Messrs. Pennock and Blackston (not W. A. B.) second. Mr. E. Mills, Sunderland, was first in Class F, "Evenly-marked Jonque Norwich," winning easily, "hands down," from Messrs. Moore & Wynn, second. Class F (Buff Norwich, evenly marked., Messrs. Moore & Wynne, first: Dr. Ellerton, Middlesborough, second. should, we think, have both been awarded to the former. Class G (Clear-crested Canary), P. Rawnsly, Bradford, first; G. Shiel, second. Class H (Dark or Grey-crested Canary), J. Stainsby, Sunderland, first; G. Shiel, second. The Golden Lizards were not particularly good. R. Hawman, Middlesborough, first; R. Rawnsly, second: but in the Silver-spangled Lizards the first-prize bird shown by Mr. James Taylor, Middlesborough, was an exceptionally fine bird; and Mr. S. McCure, Stockton, was second with a fair specimen. The Cinnamons were good classes, Messrs. Irons & Gayton being first, and R. Hawman second in Jonques, the former being first also in Buffs: Messrs. Moore & Wynn, second. Of the Yorkshire classes we can say but little, except that they were very much like inferior Norwich. The Clear Green was a good class; and we would remind friends in the south, that by Clear Green we mean a bright pea-green long bird much bred in this district, and not the bronze-green of the Norwich type. Class S (Any other variety), was not remarkable either for numbers or variety.

But what shall we say about the Goldfinch Mules? Mr. Shiel carried all before him with two birds that were not to be approached in point of excellence or condition, and had there been a third prize it must have fallen to him as well. He is one of the very few exhibitors who show birds of their own breeding only, and he must have been singularly fortunate this season, for we hear from those in the secrets of the stable, that he has others under cover destined to lower the colours of birds of known celebrity. In condition his birds cannot be excelled, and we are reminded of a letter of Mr. Ashton's, which appeared in the columns of "our Journal" some time ago on this subject. He and Mr. Shiel must have been shaking hands together!

> "To teach his grandson draughts, then,
> His leisure he'd employ,
> Until at last the old man
> Was beaten by the boy!"

The schedule was conspicuous by the absence of a class for Jonque Goldfinch Mules, and we would remind the Committee that such could not be shown in class V (Any other variety of Canary Mule). We mention this, because we have reason to believe such was the impression. A Jonque Goldfinch Mule is precisely the same variety as a Buff one, but a different class of that variety. To constitute a different variety of Canary Mule, there must be a different bird mated with it—*e.g.*, the Linnet, Siskin, Greenfinch, &c. The awards in this class fell to two very fair Linnet Mules. The winning birds in the Dark Mule classes were good specimens, and the second will beat the first when further advanced in condition. Goldfinches, Linnets, and British birds were generally well represented.

RABBITS AND THEIR JUDGES.

HAVING been from home I have only just seen the Journal, or should have sent a short and last reply to "ONE OF MANY WITNESSES," respecting the Rabbits at Whitby.

In the first place I may say with regard to the number of Rabbits, I had no wish or intention to evade the truth. As I

read the letter I took it to mean pens, and on referring to the catalogue I found, as I stated, only fourteen pens entered and three empty. In the second place, your correspondent states that I made a remark that he had to read three times over before he could believe his eyes. It was, "Had there been a large entry, of course we should have measured them." Now, I think, anyone must admit it is much easier to decide which of two Rabbits is the better when they are side by side, than to choose the best two out of twenty or more. With regard to testing the merits of the two Rabbits, let them be shown at Leeds and York; probably they will have different and, I hope, competent judges. The second-prize Rabbit at Whitby taking first at Long Sutton, is no proof that it was the best. Your correspondent mentions Wakefield, where he says they were measured and received their full share of attention; but there, I may say, all were not satisfied, for as I passed the Rabbit pens I heard a gentleman say to his friend, "See, they have reversed the Bingley decision given only a week ago." At Bingley the prizes were awarded by Mr. Teebay, who is a well-known judge and has had great experience. Lastly, as regards the statement that we judged the Rabbits in less than two minutes, I supposed it too ridiculous for anyone to believe, but as I did not look at my watch, I cannot say what the exact time was, but certainly much more than that.—JAMES DIXON.

[Here this controversy had better close. The object of our correspondent has been attained—namely, securing attention to the appointment of efficient judges for Rabbits.—EDS.]

CANARY-LOVE REVIVED.

OLD loves are very dangerous things; you may think them obliterated, that they have died out, been stamped out—you may even come to think of them as of things that had no real existence, when, lo! they revive, they re-exist, they are again as strong as ever, if not stronger. Thus, for example, a young couple perpetrated that soft thing—a mutual attachment; but stern parents on both sides forbad it sternly, a cross-grained rich old bachelor uncle buttoned up his breeches' pockets ominously (this was considered the worst sign of all), and the youth was never to see the maiden more. He was sent off to India, where he killed tigers, gained much Asiatic knowledge, and returned in twenty years' time with nearly half a liver, and as to love, so it was supposed by himself, not the least bit of a heart, when lo! he meets the lady the day he landed, *entre nous, she* managed that, and that day month they were—married. Oh! good readers, beware of old loves, they are so very apt to become young again.

I had an old love for Canaries; it existed in its strength more years ago than I care to remember, but of one thing I am sure, that the last twenty I considered myself, as to cage birds in general and Canaries in particular, "fancy free." But it so happened that I saw a paper in this Journal about the little creatures, and in a very unguarded moment, little thinking what would be the result, I read it, and liked it. At its end was to me an unknown name—"W. A. BLAKSTON." Now, I did not know Mr. Blakston in the least, never had seen him, had no interest in his interests, and was not godfather to his "Jacky;" but I will say, and quite disinterestedly, that I was so caught by the style of writing of that Canary paper that I have read every line Mr. Blakston has since written. Such is the power of a happy, pleasant style.

But more remains to be said. I have spent this year a small fortune in cages; I have even got to the length of having a Canary room, and all owing to Mr. Blakston. I think he is the real "Wizard of the North." I do not say that he ought exactly to be burnt in a Sunderland furnace; but there—he has made me during last summer chop hard-boiled eggs daily, though if there be a smell I specially detest, it is that of a hard-boiled egg; and though I am fond of a neat garden, I have come to regard chickweed and groundsel affectionately, even if in the garden. I, who for twenty good years never looked upon a Canary other than as a little yellow bird that yelped like a lonely chicken, and even hurried past Canary shops, now peep into every cage I see, look into windows if there is a cage inside, until I am afraid the police will take me for an intending burglar, got up clerically, or as Bobby might say, "doing the parson dodge." I now go into every Canary shop I see; I go and see ladies' pets, listen to their bird's song, and criticise it; I look wise at Crested Norwich, give oracular decisions about eye marks, wing marks, and tail marks; I set up my shoulders at Belgians for sympathy's sake, not horror now; I lie and wonder and suppose how very beautiful Mr. Ashton's Lizards must be; I think of going to Canary shows, leaving word with the churchwarden, "left on urgent private affairs."

And all this is owing to the Sunderland wizard. I, who positively regarded Canary people as "a little touched, you know, but perfectly harmless," now am in the fancy; Canary love has revived, and is burning so hotly that I beg space to have my say on the subject.

First, even every scoffer must own, unless he is blind and deaf, that a love of Canaries is a very general love. The other day when in London, I could but notice how many Canaries there are in every street, especially the most private streets. In better streets I saw white-banded, neatly-turned-wristed young ladies, in summer morning dresses, most becoming of dresses, hanging their pet Canaries in the morning sunshine, over the Geraniums in the window—in back streets still there were Canaries—in shops, even, Canaries. Why, I believe, if in every town in all England, all the Canaries were on a given day let out, there would be a very observable addition to our ornithology, and that in some towns the air would be full of little yellow wings.

The love of cage birds is almost universal, and, then, happily it can be followed in all places. If you pass through a London mews you will see that Larks and Thrushes are the favourites. Why? Because coachmen and their wives, and grooms (not yet bridegrooms), are from the country, and the note of a Lark or Thrush brings all the country before their eyes. As Wordsworth says when he sung the reverie of poor "Countrified Susan" living in London,

> "At the corner of Wood Street, when daylight appears,
> Hangs a Thrush that sings loud, it has sung for three years,
> Poor Susan has passed by the spot, and has heard
> In the silence of morning the song of the bird.
> 'Tis a note of enchantment, what ails her? She sees
> A mountain ascending, a vision of trees,
> Bright volume of vapour through Lothbury glide,
> And a river flows on through the vale of Cheapside."

So, doubtless, is the case in countless instances, and a Lark or a Thrush from the country brings to country-born and country-loving hearts, in populous cities pent, much of delight. But there is in my mind a thought of cruelty which spoils my happiness, when I look at a Lark or Thrush in a cage; whereas, my little friend the Canary is not "to the manor born," but "to the cage born." For three hundred years he has been hatched in a cage; it is his cradle, his home, his castle, and he, a poor feeble flier, is happiest there.

Studying, along with Mr. Blakston's commentaries (these not dull ones), the late Mr. Brent's book, I found I had good and accurate guides. Poor Brent is gone, and I like to be able to peruse the departed. Now, it is remarkable how accurately he wrote. I refer especially to his books on Pigeons and cage birds. There are no such in existence; they are original and wonderfully correct, unlike so many handbooks which are copied one from another and abound in blunders.

To those inclined to keep Canaries, or who only keep common birds, I would beg them to remember the great difference between the common coarse-bred Canary and the Fancy Norwich, the superiority of the latter to the former is very great. The common Canary, as you may see it by the dozen in low-class bird shops, is only a vulgar little fellow; shape and plumage are both wonderfully inferior to the Norwich Jonque or Mealy, who looks a high-bred little gentleman with an unsoiled coat. He costs no more to feed than a common bird; then why should he not put the vulgarian out of existence?

There is one thing for which I especially like the Canary—that is, his happy disposition. He seems an example for man; he is content, happy, and almost always merry, grateful for a little notice, as the glance of his eye (how black and bright that eye is, especially in the Clear Yellows), the nod of his shapely little head, and the jerk of his tail, plainly indicate. Not that all are alike in disposition. I have one who was intended by nature to be an old bachelor; he is shy and nervous with other birds, and prefers being hung up a little high rather than have his cage on the table. Then, I have a very vain bird; he must be noticed or he is unhappy. I take care never to pass his cage without a word and a nod. He reminds me of an oversensitive friend, who, if you pass him hurriedly on business, or suppose you have a toothache, or do not always invite him to your parties, he takes a tiff and begs to know how he has offended you. Then, the hen Canaries differ. I have a dear little hedge-sparrow-like bird (a Hedge-Sparrow to my mind always looks kind); I may shake her on her nest and she

shows no ill-temper, she is so thoroughly lame. Another lady I possess who pecks my finger under such circumstances, and sharply too.

Enjoying to the full my out-door pets, poultry and Pigeons, yet I find full often that there are days in our changeful climate when no out-door pets can be enjoyed, or even enjoy themselves, when the cock foregoes his wonted strut, and the poor hens stand miserable, even under a dry shed; days when Pigeons prefer nesting for very warmth's sake, or shelter's sake, to facing the cold winds, or the driving wet. On such days, if one is feeble in health, too, I turn to my Canaries, to my in-door pets, who care not for rude Boreas, or drenching Pluvius. Then while I write they are near me, and I can watch their habits without loss of time. Indeed, Canaries are fit pets for tailors, shoemakers, and literary men, all followers of sedentary trades. While my birds are nesting, building, sitting, and rearing their young, I love to watch them. So I find do my children, who love to gather green food in their walks for the birds at home. What basketsfull of chickweed and groundsel have they brought home this year. Then there was the grand collection of plantain spikes to be made for winter use. How they were sought and sorted; how a small forest of them was discovered in one corner of the park, and how the *Times* newspaper was made into a bag for the reception of the plantains, and how the youngest pleaded in my absence for the privilege of laying each day a spike on each cage. To give their children happiness ought to be the endeavour of all parents, and the father that keeps and breeds Canaries adds much to his children's pleasure.

Further, there is a rare beauty in canary colour; it is like no other colour, so we call it "canary." Its beauty in the birds is best seen just before a brood flies. You take the cage down, and look into the nest where the birds sit, and clean, and clear, and bright is their colour. So pure and new do the little fellows look, they are feathered, but too weak as yet to venture out of their nest. Few young birds are pretty, I think no English birds are while in the nest, but the Canary colour effects a triumph, and young nestling Canaries are very pretty. When they leave the nest by day I notice they, like other babies, must have their day sleep, sometimes on a perch, at others in the nest. But what a change do a few days make. At the month's end I take them from the old ones, and give for three days soft meat, egg, hempseed, and bread, as well as seed, but before the three days are well over, the manly little chaps despise the baby puddings, the nursery food, and there they are eating away at the seed drawer. A little older and I allow them a bath. Just like bathing school boys they do not know when to have done, when to come out of the water. Your old Canary takes his bath, has a good clean, and has finished, but the juveniles go in and in and in again. My plan in my room as to the bath, is this—I place a shallow dish, the bottom part of one of those receptacles for eggs one buys at a crockery shop, consisting of two parts, the upper an earthen hen of doubtful breed, represented sitting, and a nest basket under her. This earthen basket—a far better thing than the deep bought baths—I put on a wooden chair in the centre of my room, if possible in the sun. I open the cages and down the birds come, and verily it is a pretty sight to see five at once bathing, others by the side, or a scrimmage as to who shall get in first, while others stand dripping wet on the chair back; while upon all the sunlight is falling, lighting up the pretty canary colour. Many a half hour's pleasure do I have sitting in my bird room, half hour's sittings after meals which aid digestion.

I find that in the moulting the birds not unfrequently have a kind of asthma or huskiness, but that I can easily stop by adopting the following plan. I smear a small pebble the size of a pea with Stockholm tar, and drop the pebble into the bird's drinking glass. This I find is better than putting a few drops of the tar in the water. I renew this daily, but usually two days effect a cure. I do not approve of much green food, except in warm weather and when the birds have young ones. I do approve, on the other hand, of bruised hempseed with the chopped egg, for I have not lost one bird this year, and I know young things, children included, need nourishing food. In saying this I am telling the decided opinion of a very successful lady fancier in my own neighbourhood, who has bred Belgians for years. My birds are healthy, but then I keep them scrupulously clean, cleaning them every day. If a bird is shown to me ill I smell the drinking fountain, and—oh, faugh! It is the same with Pigeons; the same cause, the cause of fever in mankind—dirt in some form or other. In going among humble fanciers all this summer, and hearing their mournful stories of "No luck this year, sir," I asked, "Did you scald the soft-meat pans every morning?" "Well, sir, I can't say I did." "Did you give clean water daily?" "Well, no." This is the same cause in Pigeons, though the higher bred the more delicate—dirt.

I like much my Canary pets. At present they are all Norwich, Clear, or Marked, or Crested. The last when angry look like Scotch shepherds in a gale of wind with their flat bonnets on their heads. I admire the ceaseless activity and curiosity of Canaries, how they will peck at everything new, be it a bit of string or even the head of a nail—so curious, so prying, so active in body and brain are my little feathered friends. Canaries, like all cage birds, are great sources of comfort and amusement to invalids. Doubtless my readers know what a small world confirmed invalids live in. Their room is all, and if in it they have flowers and pets they get to love them very greatly. I know how a delicate child, forbidden to join in out-door exercise save in fine weather, will delight in mixing and getting anything, bath, water, &c., for the birds, and will sit and watch them by the hour. I do not wonder how general is the love of Canaries, how they are found in front streets and back streets, how they are to be seen in the wide light halls of pretty modern villas, their cages among pots of Maiden-hair Ferns and bright Geraniums. Then under how great difficulties they are bred, and bred by hundreds (Ah! Englishmen, and Englishwomen, bless them! like to triumph over difficulties), as witness in Sunderland's smoky atmosphere—Sunderland which has its large and beautiful show in spite, nay, perhaps partly because, of the difficulties to be surmounted.

And now to bring this rambling Canary paper to a close, I end it with a "Thank you, Mr. Blakston, for reviving my Canary love; for making my little children thoughtful of little birds' wants, and watchful of their ways; for helping me to educate them in kindness—yes, thank, thank you, Mr. Blakston; and like Oliver Twist, I ask for more—for papers on each variety, for points to judge them by," &c.—WILTSHIRE RECTOR.

DEAD BEES IN CELLS—QUEENS OF SECOND SWARM BREEDING.

I HAVE just taken up a second swarm; the hive is about half filled with combs, and there is very little honey but a good deal of brood. The bees are quite perfect; some of them are ready to creep out of the combs. I want to keep the hive to hive a new swarm in next year. Will the new swarm clean the dead bees out, or will the latter do any harm? It is a common hive. If a second swarm of Ligurian bees were sent away on the day it issued, would there be a sufficient number of drones with it to insure the queen finding a mate, the parent stock having a good number of drones?—H. R.

[The new swarm will remove the dead brood, and we believe sustain no injury from its presence. The hive should, however, be carefully put away in a dry place until wanted for use. If the second swarm from a stock of Italians can be placed at a sufficient distance from any common bees, it is most probable that sufficient drones would accompany it to insure the purity of the young queen's progeny.]

SPURIOUS HONEY, AND FRAUDULENT BEE-KEEPERS.

IT is with regret that I feel bound to reply to the vague and contradictory statements made by Mr. A. Pettigrew, in your issue of the 11th instant. I leave the major part of his article to the Ayrshire bee-keepers, who, I know, are very well able to defend themselves, but I will notice the salient points, giving some explanations as I go along; and may I add that Mr. Pettigrew must himself advance considerably ere he assumes to give information to others on the subject of bees? The produce of those who work on the Stewarton system is greatly superior to his currant-bun-like combs, and much has been said against the Stewarton hive by bee-keepers who are not themselves able to take off boxes of fine honeycomb.

Mr. Pettigrew says—"Some time ago a correspondent asserted in your columns that the Stewarton hive produced the finest honey in the world, an assertion rather too extravagant for your intelligent readers." Now, it seems to me that there is something rather obscure in the last two words of the sentence. As a proof of the repute of the Stewarton hive, I may state that it has come under my direct observation (not to speak *of*, perhaps, six times as many that I know nothing *of*), that there

have been exported during the last three or four years no less than one thousand sets of these boxes, and very many of them have been sent to parties who had already possessed them, and who are readers of "our Journal." Are they then not "intelligent" because they use the hive that Mr. Pettigrew condemns? It also somewhat astonishes me that he should assert that "neither the shape nor material of a hive can improve the quality of the honey." Did he not himself give instructions in this Journal as to the best shape and material for a hive? Doubtless, the shape and material have very much to do with the quality and quantity of honey collected, but as it belongs only to those advanced in the science, Mr. Pettigrew has no use for this information, and I will not trouble him with it. He says again—"I am not . . . . going to say one word for or against the Stewarton hive." He would have done as well to have "let sleeping dogs lie," since, if I may believe my own eyes, he has already said a great deal too much.

As respects feeding bees with sugar for the production of supers, where such a thing exists by all means put it down; but it is in this, as in many other things, there are but few rogues in comparison with the number of honest men, and I am almost sure he is mistaken with regard to the three boxes in question. At any rate, it would have been better if he had expressed himself in a different manner. There is, indeed, as will be seen, a singular coincidence between the boxes he mentions and three which I myself saw. I happened to be in Glasgow some time since, and in a shop there examined a quantity of honeycomb, amongst which I was shown three boxes that were to be sent to England. There was no more sugar in these boxes than there is in my pen, but there was certainly very fine honey, and if these three boxes, and the three spoken of by Mr. Pettigrew, are the same, he is beyond doubt mistaken, and ought to apologise, or to bring forward proof that their contents really were sugar, which I am almost certain they were not. It is very questionable whether feeding bees is profitable, I am sure it is not. Sugar at "2½*d.* per lb." I will pass over, because such a weak statement can have little effect on any one who reads it. He says that Glasgow merchants and judges of honey ought to taste it before purchasing. This practice bee-keepers would never submit to, as it spoils the whole appearance of a fine box. Besides, a good judge of honey knows honey and comb without tasting. With boxes raised under Mr. Pettigrew's plan, it matters not whether they be broken into or not. Who would have thought that one who reads "our Journal," would have laid any stress on such words as "he told a friend who told me!" I think I see the cunning leer the Ayrshire man put on when he told the ignorant bodies that it was sugar and water.

In a year like this it is impracticable, unprofitable, and impossible to raise supers with sugar—impracticable because the make of the hives does not admit of feeding, unprofitable because if food is given in fine weather the bees cease collecting from the fields, impossible because they will not take artificial food when they can get honey of their own gathering. I give one case in point. I had a hive whose combs met with an accident about a week after swarming; I collected the honey in a basin and gave it to another hive, but it refused it, and not one would accept it until the honey-gathering ceased.

With regard to novices passing their opinion on honey, almost all whom I meet belonging to Lanarkshire, if I show them a first-class box of honey always maintain it is sugar; again, I have met them (men from the neighbourhood of Carluke), more than once opposite the vendors of honeycomb, and whenever a spurious article was present they maintained it was honey; the rest they said was sugar. I had a visit last year from some men of that place offering for sale honey and sugar nicely compounded together. I showed them a box of honeycomb pronounced the finest they had seen by those who had judged most of the honey in Scotland. On seeing it, one exclaimed, "What is it?" while the other maintained that it was sugar! Now I can assure the readers of this Journal that the hive from which this box was taken has stood for three seasons without ever having sugar, and that during that time it has given six supers of fine comb, each 25 lbs., besides other inferior comb, such as Mr. Pettigrew boasts so much of. I say, therefore, to the readers of "our Journal," Do not believe such statements as that the Ayrshire shallow boxes are filled with sugar and water. Deal only with respectable people, of whom there are many, and you will not be disappointed.

As regards the Glasgow merchants being judges of honey, most of them know very little about it, and how can they when but few of them even know bees when they see them? A practical man is the only competent judge. I will merely instance the judgment of a Glasgow honey merchant. At the Hamilton Horticultural Society's Show, in September last, there were entered for competition seven boxes, and out of the seven, only two in my opinion deserved a prize; but, strange to say, the best box of nearly 30 lbs. of perfectly straight worker comb, every way well finished and of a fine colour, was awarded only the third prize, whilst the second best was passed over entirely, and the first prize was awarded to a box of drone-comb, not filled, of about 6 lbs. in weight, and the honey it contained of a third-class quality, having been gathered from the wild tansy—such is commonly a little bitter and tastes strongly of pollen. The second prize was awarded to a much inferior box of about the same weight, but it had only two pieces of coarse drone comb which constituted the box, the honey being of the same character as the first and very watery.

So much for the judgment of Glasgow honey merchants, which is, in fact, no better than that of the majority of the Lanarkshire bee-keepers, who, as I said before, whenever they see a fine box maintain that it is sugar; but to give your readers a better idea of how the honey was judged, I will relate the conversation that took place between the Judge and the owner of what ought to have been the first-prize box. The Judge, "Is this your whereabouts? Have you something in the show?" "O yes, I have, I have a box of honey. You would likely see it." "Yes," was the rejoinder, "Was it the large box?" "Yes," replied the owner. "Where have you placed it?" "I think," answered the Judge, "it is third." "I think you must have made a very great mistake, as there is no comparison between the boxes," continued the owner. "Oh," replied the Judge, "it was in the dark, I could not see it." "And what were you brought here for?" exclaimed the owner. "You a judge of honey!" When the Judge again replied, "I can sell wee boxes best; besides, I did not know it was yours." "Nor had you any right to know whose they were," said the owner. "And had you examined the large box you would have seen that without cutting a single comb you could have made from it seven boxes superior to those you placed before it." Your readers can guess the rest.

And, now, let me ask, if the Stewarton boxes contain sugar and water, how comes it that there are so many unfinished ones in the market? Were they filled with sugar the owners would surely look a little more after their own interests, and not send out any empty comb, as it is well known that it takes much more to build comb than to finish it.—A Lanarkshire Bee-keeper.

Mr. Pettigrew makes some observations on the Ayrshire bee-keepers that are quite amusing. Fancy a coterie met in some quiet corner, with snuff-box circulating, and may be a glass of toddy to keep up the fun, calculating to a nicety how much sugar at 4½*d.* a-pound is required to produce 1 lb. of honey. That settled, the next thing is the large profit they will have after the syrup expedition over the border. Some short time ago I tried to sell in Manchester pure honey, collected in that locality. After trying all sorts of places, and finding it quite unsaleable, I let a druggist have it at 6*d.* per pound, which he never paid. Honey from the north—how produced I cannot tell—is saleable. That produced about Manchester can scarcely be given away.—Over the Border.

AN ACCOUNT OF A STOCK OF BEES.

During the autumn of last year I bought a stock of black bees in a common straw hive. After having put them on a stand in my bee garden, I attempted to capture the black queen by fumigating the bees. The first lot of bees which fell on the floorboard were carefully searched through for the black queen, but without success. I then reserved the bees I had taken from the stock, and again fumigated the stock, which appeared to take all, or nearly all, the bees from the hive. I was quite satisfied I had sufficient bees to form a colony, to which I at once added a Ligurian queen.

Having sufficient combs already fitted into the frames of one of Pettitt's frame hives, I placed the old stock in another part of my garden to take its chance. I then put the bees which I had taken from the stock, with a Ligurian queen at their head, upon the stand formerly occupied by the old straw hive, and so made a very good stock. You may judge of my surprise in the spring of this year when I found the stock from which I had drained nearly all the bees as strong and as good as any in

my apiary, which then consisted of about twenty stocks of Ligurians.

In April last I transferred the stock from the old straw skep into Pettitt's "hive of hives," taking care to cut out all drone brood, and substitute worker comb. On May 25th I took away the black queen, which I introduced to one of my black stocks, which happened to be queenless, and introduced a Ligurian queen in her stead. On May 26th I examined and found the Ligurian queen quite at home amongst her new subjects, and was much surprised to find all the young bees in the hive were actually hybrids, each with one distinct yellow ring. On the 18th of June I removed the crown-board, and saw a number of young Italians, but none on the wing until the 23rd of June.

This stock continued to flourish until the 6th of July, when I took away five of the combs with the queen, and made an artificial swarm. The old stock produced a new queen July 21st, which has proved a prolific one, and at the present time both stocks are very strong and well populated. The old black queen continued to produce hybrids until some time in August, when she disappeared, for the hive was found to be without a queen, and not having the power to raise another, the bees gradually dwindled till none was left.—SUDBURY.

THE EXPERIENCE OF A "BEGINNER" WITH THE WOODBURY FRAME HIVE.

THIRTEEN months ago a friend of mine happened to tell me that he was going to destroy two hives of bees for the sake of their honey. I at once told him that he ought not to do so, for I had seen a plan described in THE JOURNAL OF HORTICULTURE, by means of which the honey could be taken without destroying the bees, and I then explained the process to him as well as I could. "Well," said he, "as you seem to know all about it, I will make you a present of the bees." And this was how I commenced bee-keeping. Rather a strange beginning for one who had never seen a stock driven or a swarm hived—in fact, had never before touched either a bee or a bee hive, and yet had undertaken to drive two stocks and hive them in a—well, no less than a Woodbury bar-and-frame straw hive, as I was determined, when once I made a start, to go in for the best, and become a practical bee-keeper; for, as my father's gardener says (he is a Cheshire man), "What mon has done mon can do."

I read Mr. Woodbury's very explicit articles on driving, &c., until I could almost say them word for word. I followed them out to the letter, and was perfectly successful, and most amusing was it to me to see the bees deserting their stores and running up into the empty hive. I brought them home, along with sufficient "deaf" comb to fill six frames, in which I fastened it according to Mr. Woodbury's instructions, hived the bees, and put them on their stand. Three days afterwards I examined the hive, and as the bees had cemented the combs I removed their fastenings. I fed the bees until they weighed 26 lbs. nett, and with a feeder that some of your correspondents seem to have a great deal of trouble with—viz., a pickle bottle; and for the information of your readers, I may state that their entire cost was but 10s., as they had 20 lbs. of loaf sugar, at 6d. per lb., made into 32½ lbs. of syrup. The stock wintered well, scarcely a bee dying, and by February 5th they were carrying pollen.

As spring advanced my new pets throve marvellously, and I was thinking of taking an artificial swarm, when I found that my "new-fangled hive" and driven stock were watched rather jealously, to see what results I obtained; so this determined me to put on a super, and show the unbelievers the honey-producing properties of the "patent hive," as they termed it. This I did on the 20th of May, and it was quite filled by the 10th of June, when I raised it and put another one (minus the bars) between it and the stock hive, and the bees soon enlarged their combs so as to fill this super also, and when I took it off on the 20th of July the united supers weighed 48 lbs. nett. I showed it to all the cottage bee-keepers about here, and it was very amusing to hear their remarks upon it. "It's a grand hive is that, mister," says one; "What a pratty seet" (pretty sight), says another, &c. I have stated every particular about my hive, with the exception that, not to be behindhand, I have ordered a Ligurian queen to put at the head of it.

Now, my object in writing is to thank Mr. Woodbury for giving us new beginners every information, and also for giving us a hive both simple and easily managed. I, who knew nothing at all about bees, and have had no one to instruct or help me, except what I have gleaned from your Journal, have managed it without a single mishap, and I would say to all beginning bee-keeping, Procure a Woodbury frame hive, you will be delighted with it; the difficulties about managing it are all visionary, and with a bee dress and gloves the most nervous may do anything.—A BEGINNER.

[We shall be glad to be informed from time to time of your further proceedings.—EDS. J. of H.]

OUR LETTER BOX.

FOWLS EATING THEIR EGGS (*Constant Subscriber*).—The best plan we know to cure fowls of eating their eggs, is to place composition eggs about. They must be of hard material, so that the beak can make no impression on them. They get tired of pecking at them, and give it up. As we have seldom met with it in a farmyard where fowls have their liberty, we are induced to ask whether it is general, or confined to a few birds? If, as we should think, the latter is the case, we advise you to watch them closely, and when the culprits have laid, let a boy at once rush at and frighten them off the nest. This is a certain cure. If the offenders are only two or three in number, they may be detected by the yolk hanging about their beaks, and should be killed at once, as they learn the trick one of the other.

CALL DUCKS (*Lost J. H. N.*).—The White Call Duck should be perfectly white, with orange bill and feet. The Brown should be in colour the fac-simile of Wild Ducks. There is no fixed weight, but they cannot be too small if they are symmetrical. The body should be round, and the head round and very small, with a short bill.

DORKINGS NOT LAYING (*S. P.*).—None of your adult Dorkings will lay now; it is against nature. The pullets have probably laid their eggs, and there are none of a proper age to succeed them. If there are many about nine months old, some of them must be laying if properly fed. What is sandan-mash? What is the kitchen refuse? Is it stock-meat and such like, or is it merely wash with refuse vegetables in it? The latter is not good. Feed on barley or oatmeal night and morning, and give some whole corn, barley, or maize, at midday. A good division would be—barley four times, maize three times per week. Long experience has convinced us that is the proper feeding. Constant complaints prove to us that all the new discoveries produce disappointment, and are but apologies for proper feeding. If you will feed as we have described, we have no doubt your birds will lay.

FOOD FOR FOWLS (*D. F.*).—We do not know the meal of which you speak, and have little faith in cheap things. At the price you mention we think there must be a great mixture, and some of the ingredients must be very cheap. We believe you can buy it at 2s. per bushel, because it is worth no more. Our experience is that the best food is the cheapest, and that two equal sums being judiciously laid out in food, one on the cheapest, the other on the most expensive, the latter, though much less in bulk, would afford the larger supply of nutriment. The good food of good barley has much to do with keeping your birds in condition. As a fair test withhold it for a few days, and see if they fall off; if they do, it will be a proof your meal is not of itself sufficient.

WEIGHTS OF DUCKS, GEESE, AND TURKEYS (*Amateur*).—We have known a Duck to weigh 9½ lbs., a Goose 29 lbs., a young Turkey 27 lbs., an old one 30 lbs.

DORKING WEAK-LEGGED (*H. F. H.*).—Any young cock so weak upon his legs as to squat on his knuckles, should be kept in a dry place; but rain could not have caused the weakness you mention. If it is weakness that caused him to be knock-kneed and ungainly in his figure, we have no hope of him, nor do we think him worth saving. If it be the weakness that makes him sit down, it is merely a temporary ailment, of which he will recover. Feed him on ground oats mixed with milk, on cooked meat chopped fine, on bread steeped in strong beer; and if you think him worth it, on boiled egg chopped.

COCK CANARY UNWELL (*J. T.*).—Give this bird which snaps his bill all day, and is songless, a drop of castor oil, and hang the cage away from draughts.

WINE PRESS (*G. H.*).—One is described and figured in No. 435 of this Journal.

SALT-CAT (*A. L.*).—The salt-cat is composed of about equal quantities of a clean, unctuous loam, such as brickmakers use; a coarse gritty sand, or fine gravel, in which the grains are about the size of pins' heads, and old mortar; to this is added a small quantity of bay salt. Some persons, to make it more attractive, add aromatic seeds, such as cummin, anise, coriander, and caraway. The whole should be mixed with water to the consistency of mortar, and placed in a crock, the sides of which are perforated with many holes, large enough to admit the Pigeons' heads, and covered with a lid to keep off the weather.

HONEY FROM A FOUL-BROODED HIVE (*Inquirer*).—It is stated that the virus of honey which is tainted with the foul brood may be completely eradicated by boiling; but we have ourselves had no experience on the point; 17 lbs. of honey are not too much, as bees do not store all that is given to them. Breeding is pretty certain to recommence with the excitement of feeding; and the re-appearance of foul brood, supposing the colony to be really infected with the disease, is the too probable result.

POULTRY MARKET.—OCTOBER 27.

OUR market is more cheerful, and if the weather remain cool we may look for good autumn prices.

From observations taken near London during the last forty-two years, the average day temperatnre of the week is 51 7°; and its night temperature 35.7°. The greatest heat was 63°, on the 5th, 1852, and 6th, 1834; and the lowest cold 17°, on the 9th, 1834. The greatest fall of rain was 1.02 inch.

GRAPE-GROWING IN SCOTLAND.

ALTHOUGH the Vine is not a plant indigenous to this country (England), we have long claimed the honour of being its chief and foremost cultivators. If sunny France and Spain have been able to show us their vineyards, and to let us taste their wines, we in turn have boasted, and honestly so, of our vineries—of our Grapes. We have been able to show them such Grapes as completely to astound by their magnificence. As if to keep men and things on a sort of equality, it seems to be a settled law, that where "Nature doth most, man doth least." This law is well exemplified in the case of the Vine; for where the natural climate is the most favourable for the production of Grapes, it is there that the most miserable fruit are produced. We improve upon, or rather assist, Nature in this way—we make up for the want of a natural climate for the Vine by an artificial one. We receive the Vines from southern Europe, and send thither the fruit, as examples of our skill, so much altered and improved that the original is almost lost sight of and unrecognisable. We take credit for our successes, and attribute them all to our superior management, to the greater attention we pay to cultivation. Granted that we do all this; experienced cultivators have, however, proved that it is more easy to produce good Grapes in this country than in their native climes. Why, we will not inquire; for, be that as it may, the gardeners of England have long pre-eminently shone, and enjoyed the prestige as the champion Grape-growers of the world.

How long will this last? however, we inquire. How long shall we the gardeners of England sustain this proud reputation? Passing events would seem to say that the glory is passing from us. We read of a Great International Fruit (Grape) Show in Edinburgh, where, if the words of the Rev. S. Reynolds Hole be true, that "defeat was glory," what must victory have been? We hear on every side accounts of this as the greatest and finest exhibition of Grapes that has yet been seen. And from whence came they—they, the victors? From the foot of the Grampian Hills—from the borders of the Highlands of Scotland. Good Grapes were there as well from many other parts of Scotland; good Grapes were there from England—from England's champion growers—yet the glory of the contest, the place of honour, was undeniably won by Scotland; and honour to whom honour is due.

It is not a great many years since it was a settled article of belief amongst English cultivators, yes, and Scotch ones too, that first-class highly-finished Grapes could not be produced north of the Tweed, however great the skill, or however much the care taken in their cultivation; the climate was too cold, the summers were too short and sunless, &c. Is it the climate or the seasons, then, that have altered? or is it the cultivators who have triumphed over and surmounted the difficulty, if such there was? We have no evidence of the former, therefore the entire credit is due to the latter. I do not affirm that Grapes are more difficult of cultivation in the northern part of the kingdom than in the southern. I simply call attention to this noteworthy fact, that the finest Grapes, both for appearance and flavour, at the late show came from the most northern exhibitors. I call attention to the remarkable excellence to which Grape cultivation has now arrived in Scotland, and note the exceedingly rapid progress made in that one department during the last few years.

When the first International Fruit Show was projected in Edinburgh, we in the south had little fear for our "laurels." It was, however, with something akin to astonishment that we were met with the magnificent productions of Mr. Fowler, of Castle Kennedy, and Mr. Thomson, of Dalkeith. This year we have been again invited to the fight, again to be vanquished, this time more smartly than ever. Again we have had a new antagonist to encounter; this time it is Mr. George Johnston, gardener to the Earl of Strathmore, Glamis Castle, Forfarshire, who for his signal successes, having obtained eleven first prizes for Grapes, must be designated the champion amongst Grape cultivators.

It may be inquired by those who have not been able to see for themselves whether these Grapes, which have excited so much interest, were superior, or even equal, to those usually to be seen at our own exhibitions—in our own gardens? I dare to say they were, and very much so. The Grapes exhibited at our southern horticultural shows latterly have been, with a few exceptions, notoriously indifferent in quality. There has been a very perceptible falling off in the general muster of the Grapes at our shows during the past two or three years, in spite of all our boasted improvements in their culture. Grapes are certainly not so well represented now at our exhibitions as they were even six or eight years ago. It may be argued that we have had no good autumnal exhibition calling for a display of this kingly fruit. This is quite true, but independently of all that, I venture to say that we, as a nation of Grape cultivators, are sleeping in our spurs meditating on past glories, while our northern friends are prancing triumphantly ahead of us.

We are enabled to see that which is, we can also contemplate that which has been. Twenty years ago could we have written thus of the Grapes in Scotland? Scarcely; for every good bunch that could have been found then, I will engage to find thousands now—yes, and thousands finer. It is not a difficult matter to trace the source, to discover the cause, of this great impetus in Grape-growing. I have but to point to the man. I have but to name Mr. Thomson, of Dalkeith. From the very day that he recrossed the border on taking charge of the gardens at Dalkeith, then world-famous through his predecessor the great Mr. McIntosh, horticulture, in especial Grape culture, has made rapid progress in the north. By his own noble example of culture at Dalkeith; by his practical instructions so clearly given in his book on "The Vine;" by his able editorship of "The Gardener," a publication enjoying the confidence of most practical gardeners; by

his skilful advice so freely given, the encouragement bestowed, and the little inducements leading people on so continuously at play, Mr. Thomson has done more to engender a love of gardening, to popularise and extend the cultivation of Grapes, in Scotland than any man ever did. Scotchmen, therefore, one and all, owe him a deep debt of gratitude. I believe I am not doing any harm in stating that the famous vineries and Vine borders at Castle Kennedy, so ably managed by Mr. Fowler, were formed from Mr. Thomson's plans. Then, again, the vineries and borders at Glamis Castle have been made by Mr. Fowler after the same model. I can also point to some vineries at Mr. Lindsay's, near Dalkeith, 200 feet in length, with the most enormous crop of good fruit I have ever seen, a perfect mine of wealth to their possessor, and to another lot at Mr. Christie's, Craigend, which will next year astonish the world unless I am much mistaken. Such rods of only one season's growth I could never have believed possible to be produced. At Hopetoun House, also, the Grapes are most meritorious, and highly creditable to Mr. Niven, although produced under disadvantageous circumstances. Those at Lochryan House may also be noted as praiseworthy, and lastly, the production of that Brobdingnagian bunch of Syrian at Askelton Gardens by Mr. Dickson, weighing 16½ lbs.! the largest bunch ever produced since the famous one of Speechley, which required two men to carry it.

At another time I shall have more to say in detail on some of the Grapes in Scotland. At present I call my brethren's attention to our defeat. The mantle lies on the other side of the Tweed at present. Who is the southron bold enough and strong enough to take it up, and wear it? Let us try; for, in the immortal words of Nelson, "England expects that every (garden) man (with Grapes) will do his duty."—ARCHAMBAUD.

THE CULTIVATION OF HYACINTHS IN THE OPEN GROUND.

THIS is a continuation of the subject of spring decoration touched on in the preceding papers. Actually the Hyacinth is but little known as a border plant, probably for two reasons—First, because it is thought to be an expensive bedder; and, secondly, because the flowers are so liable to be injured by exposure to adverse weather. No doubt the first is the great difficulty, and yet the display is so great, and so thoroughly enjoyable, as to serve as a set-off in a remarkable degree to the matter of expense. This last item is apt to be unduly magnified, and many are thereby deterred from making an attempt. There is also the impression abroad that the climate of England is unsuited to their growth, except for the first year of their importation. There is much reason to doubt the correctness of this conclusion, and one who has visited Holland has left on record the results of his observations, as follows:—"I question the correctness of this opinion: first, because the neighbourhood of Haarlem, the great region of their production, is on the same parallel with the centre of England, nor is the difference of climate at the season of the year when Hyacinths are under its influence, perceptible in other things; secondly, because the method of curing the bulbs pursued by the Dutch, is never, so far as I have been able to learn, fairly tried in England, nor is the soil or place of their growth out of doors regulated by a due knowledge of the wants and habits of the plant; and, lastly, because under certain circumstances it has happened, that persons who plant their forced Hyacinths, after flowering, in the open borders, and leave them undisturbed, have found in a year or two, that the self-acclimatising power of Nature has restored some of these exhausted bulbs to their original powers of blooming. Now, if this happened but once, it would show the recovery to be possible; but, in fact, it happens often, and when no particular care is taken, leaving us to suppose that it arises from the bulb meeting with some peculiar soil and locality which agrees with its constitution. And this I take to be the true cause of the restoration; so that sufficient encouragement is really given to those who have the opportunity and the will to attempt the native growth of this beautiful and fragrant flower in England." This passage is a suggestive one, and certainly contains much to arrest attention and challenge consideration. To the rich—those who can afford to purchase yearly several hundred Hyacinths for bedding purposes—the matter is but of small moment; to those who cannot afford to purchase yearly, and who would be glad to know some mode of utilising their bulbs, so as to render service for a few years in succession, the matter is one of importance.

I am of opinion that the constitution of the soil is of the first moment in the cultivation of the Hyacinth in the open ground. The soil of the bulb fields of Haarlem is either a light but rich sandy peat, or pure sea sand rich in saline matter. It is in this that the bulbous and tuberous plants thrive so surprisingly, "and I believe that it is the soil and the mode of cultivation" (so says an observant visitor), "not the climate, that make the difference between the English and the Dutch-grown Hyacinth." It is a fact that in this Haarlem soil the roots of the Hyacinth have been known to penetrate to the depth of 3 feet. This suggests a depth of soil admitting of the Hyacinth rooting deeply, though a depth of 3 feet would not nearly be reached as a general rule. Some drainage is requisite; perhaps nothing could be better than a thin substratum of brick rubble similar to that used by Mr. Gibson for a like purpose at the bottom of those glorious subtropical beds in Battersea Park; for though drainage may seem to be of little consequence to a plant that grows well in water alone, yet this would be found a mistake, as in cold, sodden earth the roots canker, decay, and perish, as soon as those of any other plant. Depth, pabulum, freedom, are the watchwords of a fine old cultivator of the Hyacinth in the open ground, and they are the secrets of the cultural process that assuredly lead to success.

Some twelve years ago one of the most successful cultivators of the Hyacinth in the open ground was the Rev. W. Le Poer Trench, D.D., of Moylough Rectory, Ballinasloe, Ireland. Probably the climate was to some extent favourable, but the circumstance teaches how much can be done by paying some attention to the requirements of the plant. Only fancy "flowering the same root for fifteen consecutive years to a degree of perfection fit for any show stand;" and yet this is what Dr. Trench did at the time I have stated, and for aught I know to the contrary, may be doing still; and what was equally remarkable, Dr. Trench also brought forward offsets to a flowering state equal to the best imported roots. The mode of cultivation adopted by Dr. Trench can be best given in his own words. "I empty out the bed in the first week in October, fully two spades deep. I then fill it up, one spade high, with pure fresh cow dung, separated as much as possible from straw, mixed with an equal portion of half-decayed leaves—say one year old. The remainder of the bed is then filled up with well-decayed leaf mould (two years old) three parts, and fine pit sand (if I could get it I would use sea sand) one part. Of course, the bed is raised to the usual height in the centre, and the substratum of cow dung and leaf mould is raised in proportion, so as to bring it in the centre, as well as at the edges, within about 16 or 18 inches of the surface. I plant in the first week in November. I empty out, with the hand, the space in which each root is to be deposited, removing the compost to such a depth that the crown of the root, be it large or small, shall be 2 inches below the surface. The hole being thus opened, I sprinkle some sand, about the fourth of an inch in depth, on the bottom; I then deposit the root upon the sand, and cover it all round and over with sand. If there are any promising offsets, I plant in the same way round the parent, only, of course, placing them nearer to the surface. In every future year after the first, when the bed is emptied out, the bottom and top stuff are carefully mixed together, and one-eighth part of sand is incorporated with them, and that is used for the top-filling, instead of the leaf mould and sand. I never permit offsets to flower until the bulb has attained the full size. I do not protect in any way until the florets are beginning to expand, and then I cover with an awning, which is not removed until the bulbs are taken up. Every flower-stem is cut off as soon as the beauty of the bloom is past. The bulbs are taken up when the foliage turns yellow, and dried in an airy, shady loft. The withered foliage and all offsets are then removed, the bulbs cleaned, and put by in silver paper, in a paper bag, duly labelled, until the ensuing planting time."

I trust the re-appearance of these admirable rules will induce many of your readers to attempt the cultivation of the Hyacinth in this manner, as it is quite certain that there is no necessity for abandoning the bulbs after the first year's flowering. A dry and airy part of the garden should be selected as the situation for the bed; a southern aspect is to be preferred, and if there can be added some shelter on the north and east sides, either by trees or buildings, or evergreens, the beauty and duration of the bloom will be benefited thereby. It need scarcely be stated that the bed should be beyond the reach of any drip from the trees.

The earlier-blooming sorts of Hyacinths, information regarding which can only be obtained by experience, should be

planted from 1 to 2 inches deeper than the rest, so that all may be in bloom at one time. This is supposing several sorts and colours to be used. As a general rule, the blue flowers are the earliest to bloom, and the deepest in colour the first, the red next, the white third, and the yellow last.

A bed of Hyacinths scarcely ever, or never, requires watering at any period; the rains that happen after planting are generally more than sufficient, both for the roots and bloom, and after the bloom is over they are rather prejudicial than otherwise, unless very moderate. In the case of severe frost, especially if it follows soon after rain, some protection should be given, and it will be the more necessary if the bed occupy an exposed position.

How finely Hyacinths can be bloomed in the open ground is wonderfully illustrated each spring in the pretty and pleasant spring garden at Glen Eyre, Southampton, the seat of Mrs. Eyre Crabbe. Though the bulbs employed represent only the ordinary mixed border Hyacinths sold at the shops, they yet produce heads of bloom that would be thought much of if they could be so produced in pots. Nearly a thousand Hyacinths are bedded out each autumn, generally in long serpentine beds, in lines of red, white, and blue; they are the feature of the garden, and make a display that can alone be appreciated by those who look upon them. It is now the custom for the leading Hyacinth-dealers to import from Holland specially for bedding purposes second-sized bulbs of leading sorts like Baron Van Tuyll, Charles Dickens, and Emicus among the single, and Bloksberg, King of Wurtemburg, and Richard Steele among the double, blue flowers; Duchess of Richmond, Madame Hodson, Norma, and Robert Steiger among the single, and Grootvorst and Waterloo among the double, red flowers; Grand Vainqueur, Themistocles, and Voltaire among the single, and Anna Maria, La Tour d'Auvergne, and La Virginité among the double, whites; and a few shades of yellow as well. These are well adapted for bedding, and there is the additional advantage of securing uniformity in height and hue for any special purpose.

I trust I shall have carried with me not only the sympathies, but also the resolves, of many of your readers, and that they also will strive to emulate in some degree what is being so worthily done by others with the Hyacinth in the open ground. It is not too late to make an attempt in the present autumn, and there is ample material at hand for those who want it. To such, if they labour well and patiently, a large result will accrue as their fitting reward; and when the forerunner of spring shall call into active play the forces hitherto unseen, but none the less contributory, that compose its gentle government, they will see that which sweetens labour, gladdens the eyes, and brings reverent thoughts to the heart.—Via.

THE GOLDEN CHAMPION GRAPE VINE.

As the raiser of this Grape, I regret to observe that writers in the columns of the Journal have failed in growing it satisfactorily. They seem to think that its constitution has been debilitated by excessive propagation, but I do not think this has been the case. I have seen it growing in many gardens this year, and with one exception, in great vigour. Mr. Barron, of Chiswick, called here lately, and I took him to see a garden in this neighbourhood, where the Vine had made rods like walking sticks. I recently called at Airthrey Castle, the seat of Lord Abercromby, where I saw a houseful of Vines that were planted last May; they were all vigorous, and up to the top of the house, but the Golden Champion was by far the strongest in the house. I could name a dozen such cases, but will only add that my brother, on taking the management of the gardens at Drumlanrig, found it necessary to renew the Vines, and determined to plant fifteen Vines of the Golden Champion. Some of these I sent him, and others he raised from eyes this spring. I have not seen them, but those who have tell me that they are, without exception, the strongest Vines of their age they ever saw. With me here, it grows alike vigorously either grafted or on its own roots.

Now, for the exception to this rule, as far as my own observation goes. The gentleman had the plant from me, and not from Messrs. Osborn. I saw it some three months after it was planted; it had made a miserable shoot about 6 inches long, and there it stopped. I took it out of the soil, and the conclusion I came to was, that the plant, when in a dormant state, had been kept far too dry, and the strong and fleshy roots this Vine makes had all perished before it was planted. Strong bottom heat alone could have started it into growth. If in this I am correct, there may have been many such cases, and no Vine I am acquainted with is so likely to suffer from such a cause as this is, from the fleshy nature of its roots. My brother fruited it on its own roots at Archerfield, and the fact that on entering on the management of a garden like Drumlanrig he has at once planted fifteen canes of it, bears sufficient testimony to the high estimate he has formed of its merits.

I see it noted by a writer that this Grape is liable to be spotted. This took place in one house here during the present year to a small extent, where an overdose of sulphur was applied to the pipes, but in no other case; it was purely exceptional, and other Grapes in the same house were also affected, though in a less degree.—W. Thomson, *Dalkeith Park*.

CHOICE EXOTIC FERNS.

Cheilanthes elegans is an exceedingly pretty, neat-habited species, and one of the most beautiful of the tropical American Ferns. I have a specimen in a No. 1 pot. It is one of the most beautiful Ferns I know. I have had my specimen now three years, and feel well repaid for the care I have taken of it.

The mode in which I have best succeeded in growing it is potting it in a No. 2 pot, with good drainage. I use charcoal broken up finely in compost, and when potted I put it into a No. 1 pot, and fill up to the rim with cocoa-nut fibre the space between the two pots; I then plunge the plant in gentle bottom heat. It requires shade; mine is under the shade of a plant of Musa Cavendishii, is quite 2½ feet in diameter, and is exceedingly fine for exhibition purposes and the decoration of the stove.

Gymnogramma Laucheana.—This is one of the best of Golden Ferns, and with me is very free-growing. The under sides of the fronds are thickly covered with golden powder; the upper surface is of a most beautiful green. A fine specimen of this Fern is very effective and beautiful.

Gymnogramma chrysophylla aurea.—Although old, this is one of the best of the Golden Ferns, and is very easily grown. I have a specimen in a No. 1 pot with lovely fronds reaching over the rim. In my opinion there is not a more beautiful Fern. It is also very useful and effective for the decoration of the dinner-table when it is grown in small pots.

Lomaria gibba.—Of this I have a most beautiful specimen in a No. 1 pot, with a stem upwards of a foot in height, and resembling a miniature tree Fern. This Lomaria is well adapted for exhibition and other decorative purposes.

Gymnogramma pulchella.—This is one of the finest Silver Ferns I know, and is of very free growth. The beautiful silvery fronds are much more graceful than those of G. tartarea. I have a fine specimen of it, and it bids fair to stand in the front of our Fern houses.

Blechnum corcovadense.—I have a plant with fronds upwards of a yard in length. I recently saw a specimen of it in Sussex, the finest I have ever seen. This Blechnum is valuable for the decoration of the stove, and for exhibition. I could mention many other beautiful Ferns, but my object in offering these notes is to induce others to state what Ferns succeed well with them. There are many kinds not worth growing. When I see a good free-growing Fern I make a note of it, and obtain a plant as soon as possible.—F. P. L.

NEW GLADIOLUSES.

On receiving Messrs. Verdier's lists from Paris I found that there was a considerable difference in the names of those given there and those given in my notes taken at Fontainebleau. I therefore at once wrote to M. Souchet, and send herewith his answer. He says some changes have been made in the names, and sends me the following memorandum:—Robert Fortune has been changed to Rosa Bonheur, Rosita to Armide, Maxima to Lacépède, Asmodée to Horace, Gloria Florum to Canova, Pétrarque to Pericles, Phœnix to Robert Fortune, and Eléonore has not been sent out, as it was not sufficiently increased to enable him to do so.

It may be some consolation to those who are bewailing losses among their bulbs, that M. Souchet complains of a very sensible loss among his cultures. With regard to any advice as to the new ones, which I have been solicited to give by several correspondents, my decided opinion is, from the experience of past years, and from what I saw at M. Souchet's, that if a limited sum has to be laid out in new varieties it would be

better to select those in the first and second series; for although occasionally some of the other series may be desirable, yet it is only an exceptional case, and for the last few years the dearest varieties have been the best. If the pocket allow it, I should advise the series of twenty-four; the remaining nine I know nothing of.—D., *Deal.*

MILDEW ON ROSES.

I, IN my turn, would like to be of use if can, and I venture to send you a receipt for the cure of mildew on Roses. I may state at once that this is not a discovery of my own, but a remedy recommended to me by a lady who is a most successful grower of flowers, and she received it from a nurseryman. I assert that it is a complete cure. Rub down in a gallon of soft water 1 lb. of soft soap; with the solution syringe the upper and under surfaces of the foliage, and the mildew will disappear as if by magic. Mr. Rivers recommends a cure in soot. Perhaps soap is more cleanly; it is, I am sure, as effectual—though I do not for a moment doubt the efficacy of soot—and an outlay of one shilling will clear one hundred plants from every vestige of the disease if properly applied. I find it useful to syringe the trees with clear water next day to rid them of the whitish deposit which fixes on the edges of the leaves after the application of the solution. There is no necessity to cut off the blooms; the solution could only damage these in proportion to the force with which it hit them, and as contact with the mildew is all that is required, no force is necessary.—J. G. S.

VINE-GRAFTING, POLE-TRAINING, &c.

I HOPE "A READER" (page 328), as well as others, may find the following answers to his questions useful:—

First, "degree and source of heat?" I think it only proper to state, that the Vines now fruiting had been grown altogether out of doors, and the fruit ripened in that way. The house, 40 feet by 16, was constructed by myself ready for the glass, but that was not fixed into the rafter sash-bars till the beginning of December, 1868, and then only to protect the roots from being sodden with snow and rain. No heat of any kind was given, except that which could be obtained from the sun, till the middle of September, 1869. On the 20th of that month the first fire was lighted in the iron stove lined with fire brick, to finish off the Grapes and harden the canes for next year's duty. The stove contains about a cubic foot of small coke, and there is a 4-inch pipe through the roof for smoke. The temperature of the house for several mornings when the young bunches appeared, was as low as 34°, and not more than 50° with sun at midday—have the kindness to remember the very long cold spring of this year. During the summer, when I obtained 75° with sun, every opening for air—the doors at each end, the wood flaps front and back—was set open. At no time, even during frost, day or night, is the house totally closed. The glass is so placed at the top and each end, that a stream of fresh air is constantly passing through the house day and night. This is of vital importance to all plants.

"Are such Grapes pole-grown?" Yes. My poles are some of them 7, and others 9 feet long. The slope of the roof gives this. Some of the Vines have two poles, some four poles to a stool. This depends on the vigour of the plant. Again, I have Vines which in time will want eight poles; this will give—say 72 feet run of cane, enough to maintain a plant in robust health, consequently highly fruitful. I do not confine my Vines to any given number of poles; the vigour of the plant and the cultivator's judgment must do this; but in no case would I confine a strong, robust Vine to two poles when it was able to fill four, yet I think eight poles of 9-feet length quite sufficient scope. In all pole-training, one-third more length of rod for fruiting is obtained, let the size of the house be what it may; also the great advantage of sun heat to the roots upon the inside border, and being able to grow pot plants, or protect them, which cannot be done when the roof is a mass of Vine leaves, as when Vines are trained to the rafters. Again, the Vines are warmer, being more in the body of the house, and the foliage not so exposed to cold as when roof-trained.

"In borders, or pots?" Part of the Vines are in the borders, and part in large pots, as I contemplated the removal of some of the Vines to give room to others. The Vines in pots had all the holes in the pots' bottoms made very large to enable the roots to run out, and the pots were sunk deeply enough for the roots to run out over the rims as well.

Pruning. I am adopting two distinct modes. First, if the Vine has four poles, I let two rods produce Grapes, while grow two rods for the next year's fruiting. Those which have fruited I cut away as closely to the earth as possible, leaving one eye only to produce the rod to fruit again. If a two-pole Vine, I fruit one rod; if an eight-pole Vine I fruit four poles.

I may distinguish another method of pruning, as No. 2. It will not matter if the Vine is a two or an eight-pole one, as in this case I fruit a rod to every pole; therefore, I obtain a double crop, as compared with the first method of pruning; but to make up for the work imposed on the Vine, I fruit every other Vine; thus, if Vine No. 1 fruited all its rods this year, when the Grapes are gathered it is cut down to the earth, and next year it grows canes only for again fruiting the year after. So, in one case I fruit every alternate cane, and in the other every alternate Vine. Which of these two methods I may adopt, time must decide, or possibly the habit and constitution of any particular Vine.

My house is a lean-to, but I prefer a span-roof with a sharp-pitched roof. Any lady or gentleman can view this house of Vines by calling and leaving a card of address at my dwelling; and if "A READER" thinks of planting, do not forget a grafted plant of Chasouch. All who taste say it is delicious, and should he give me a call, he shall have a berry to decide for himself, provided the call be made within fifteen days, as I have only a bunch left, and that will be at the Royal Horticultural Society's meeting, on Tuesday, the 16th of November.—R. M. W., *Mount Pisgah, near Sheffield.*

GYMNOSTACHYUM PEARCEI AND VERSCHAFFELTI.

"F. P. L.," page 319, highly recommends Gymnostachyum Verschaffelti and Pearcei. They are worthy of all his praise; their charms are not transient, but the longer we look at them the more we see to admire. In the leaves of these plants, as it were the mystic works of Nature, how interesting to trace the ramifications of the veins carrying life to every part and extremity of the leaves! How supremely skilfully these supply-pipes are laid! In truth, as "F. P. L." says, every leaf is a complete bouquet; it is this and more—it is a book, teaching skill, and care, and beauty, and wisdom—read it. I can never think of the Gymnostachyums without associating with them their equally beautiful ally, Fittonia argyroneura; twin sisters in form, beauty, and decorative adaptability, they should never be separated.

In addition to the mode of culture noticed by "F. P. L.," they are very fine as pyramids; fill a large pot or pan with soil, insert round its sides stakes of strong wire, and fasten them together to a circle of wire at the top, of sufficient diameter to allow of a pot falling in and fastening itself. Other circles of wire must be fastened round the uprights for firmness. Have ready a lot of small, fresh-struck plants; put a row round the edge of the pot; then put in the trellis a layer of soil, finishing on the outside neatly and firmly with moss. Continue to build up with soil and plants until the top is reached. Finish by inserting a pot containing a plant in the top. This is better than bringing the wires together to a point, as the pot can at any time be lifted out, and sufficient water can be poured in the cavity to percolate the entire pyramid of soil. The soil for this purpose should be very open; lumpy peat, perfectly dry cow dung, cocoa-nut fibre, or chopped moss and lumps of charcoal, will be suitable. The amount of house room, and number of plants at command, will determine whether the pyramid be 1 or 10 feet high. Such pyramids are really fine objects, and are now a distinctive feature in most large collections of stove plants.

The plants should be put in early in spring, when a brisk heat and plenty of atmospheric moisture can be provided them, and they will make rapid progress.

These plants, and especially Fittonias, delight in a shaded place. Direct sunlight mars their beauty. It is to me a little singular, that with two plants standing close together, while the brown scale makes determined and persistent attacks on the Gymnostachyum, it never attempts a lodgement on the Fittonia, nor are either of them troubled by any other insects that I am aware of.—J. W.

SOOT AS A REMEDY FOR MILDEW.—After a practice of two seasons in occasionally dusting my store Verbenas with soot, I find it better than other things I have tried, keeping the

plants free from insects and mildew, and in good health. To be efficient the dusting must be thoroughly done; not only the upper, but the under sides of the leaves and the stems must be completely blackened, and remain so for forty-eight hours at a time.—J. W.

POT VINES.

Since writing my little work on the Vine, several persons have asked me why I did not write a chapter on the cultivation of pot Vines. As I hear a third edition will soon be required, I think of adding a few words on this part of the subject.

Several years since three different gentlemen told me they had purchased Black Hamburgh Vines at 10*s.* 6*d.* and 15*s.* each, which had never shown a single bunch of fruit. If one person had told me this, I should have thought it hardly possible. When it was first mentioned I said, "Of course, they must have been strong canes, and appeared well ripened, or you would never have paid such a high price for them. Now, in grafting Muscat Hamburgh on the Black Hamburgh, our men always choose for scions the weakest Vines we have left, and yet many of these weak grafts show fruit. Customers of mine who have bought common planting canes at 5*s.* each, have shown me the same Vines carrying nine or ten bunches of good Grapes. How, then, is it possible such Vines as you describe could fail to fruit?" For the last year or two I have kept this problem in mind, and have at last, I think, solved it. It is quite clear, as all growers of pot Vines know, that if during a great part of the season anything had been wrong, they would never in appearance even have made fruiting canes. The soil must be suitable, heat sufficient without being too great, watering carefully attended to, if Vines are to be strong in one season; indeed, a very trifling neglect will destroy all hopes of good pot Vines. It was, then, after their growth was completed, that these barren Vines were injured. I learnt, on inquiry, that whilst yet quite green water was withheld from them entirely, to ripen them and make them drop their leaves. Is it wonderful that Vines so treated should not fruit?

This great anxiety to get rid of foliage, as a proof of ripeness, is productive of great injury. I always act on the exactly contrary idea, and believe everything should be done to preserve the foliage to as late a period as possible. Vines ought never to suffer from want of water even during winter, when devoid of leaves, much less when in leaf. To prevent Vines suffering from drought, it is not necessary to keep them sodden with water. Careful watering, guided by intelligence, is, perhaps, the greatest point in the cultivation of all plants under glass, but it certainly is so in Vines. I remember Mr. Thomson, of Dalkeith, showing me two sets of pot Vines, grown in the same house, in the same-sized pots, and the same soil, one of which was as good again as the other. "There," said he, "you see the effect of watering; two men had charge of these Vines, and watering has been the only cause why one lot is so superior to the other, and yet I thought both careful men."

It is a common remark, "That no one knows how fat a beast will turn out so well as the feeder," and I fancy the ripeness of Vines is best known to those who have had the care of them. Last year I had a lot of fine pot Vines, which many gardeners told me were not ripe, because the leaves were green up to October. I knew they had been ripe for many weeks. Now these same Vines were forced early at Chatsworth, and produced many bunches of 3 lbs. weight. It was lucky they were in such skilful hands; but if they had been unripe, even a Speed could not have produced such Grapes.—J. R. Pearson, *Chilwell.*

Gardeners' Dinner and Presentation at Altrincham.—The name of Mr. Thomas Baines, gardener to Horatio Micholls, Esq., of Summerfield, Bowdon, has been for a number of years known to, and highly respected by, the lovers of horticulture. Owing to the removal of Mr. Micholls to London, and Mr. Baines leaving, it was thought desirable by a number of friends of Mr. Baines, that some tangible token of their esteem should be presented to him before leaving the neighbourhood, and the presentation took place on the 27th ult., at the Axe and Cleaver Inn. A party of thirty-two subscribers and friends sat down to dinner at seven o'clock. After dinner, the Chairman handed to Mr. Baines the following address, illuminated on vellum, and mounted in a handsome gilt frame:—"Presented, with a gold watch, to Mr. Thomas Baines, by the gardeners and friends of Altrincham, Bowdon, &c., on his leaving the neighbourhood, as a mark of their esteem and regard.—October 27th, 1869." He then presented a very handsome and massive gold watch, bearing the following inscription:—"Presented to Mr. Thomas Baines, by the gardeners and friends, as a mark of esteem, on his leaving the neighbourhood of Altrincham and Bowdon.—October 27th, 1869."

TEA-SCENTED ROSES.

Having been for many years an ardent admirer of the Rose, but especially of that deservedly popular class the Tea-scented varieties, so remarkable for free-blooming, fragrance, and delicacy of tint, I determined on paying Mr. Pavitt, of Bath, a visit, where, I felt sure, I should find a fine collection of these his special favourites, of which he is an enthusiastic cultivator. I wish now to give the readers of this Journal a few notes of my visit to the nursery.

The plants were robust and healthy; some of them were growing on the Briar, but they were principally on their own roots, and even on the 12th of October in a sheet of blossom, reminding me more of May than the present autumnal season. I found more than seventy varieties in bloom, and scarcely knew which to admire most; but I particularly noticed Adam, Moiret, Souvenir d'un Ami, Niphetos, Madame Willermoz, and Souvenir d'Elise as very fine, and as sorts that will hold their own in every choice collection. I also noticed Jaune d'Or and Madame Falcot, both lovely; Madame Charles, new, and an improved Abricoté; Marie Sisley, a charming novelty, a perpetual Blairii, and a decided acquisition; Adrienne Christophle, quite a new colour and very distinct; and the most glorious of all free-flowering Roses, Maréchal Niel, which seems to luxuriate in Mr. Pavitt's nursery, and is, I think, his special favourite, for he sends whole bouquets of them to his numerous horticultural friends. I will only add that I hope to see many of the Tea-scented class take a much more prominent position in every garden, for what can be more beautiful?—A. A.

UNFRUITFUL FIG TREES.

A lady, "Mrs. J. W.," has a Fig tree rather thick in its wood, of which we recommend her to thin out a portion of the oldest, that the wood left may be more exposed to the sun and air. That, however, of itself will not check luxuriance, and we have no doubt her tree is too luxuriant. The Fig tree will always bear best on short-jointed firm wood, and all the more if the wood made every season is only a few inches instead of a foot or two in length. The most radical remedy is to root-prune the tree, removing the earth on one side so as to get beneath it, cutting through all tap roots, if any, and shortening all that extend above 4 feet from the tree; drain the space well, build a wall or use other means to prevent the roots running further, and pack the roots left in fresh turfy soil with a little lime rubbish in it, and water rather liberally in dry weather in summer. The Fig tree, when growing, likes moisture, but it must pass away freely.

If this is too much labour, then we would advise ringing all the main branches near the bole, taking out the bark close down to the wood for a quarter of an inch wide, and doing it again if the ring heal over without checking luxuriance. We some time ago saw two Fig trees against a wall, the one very luxuriant but almost barren, the other very moderate in its luxuriance but loaded with Figs, the joints of the wood being very close together. Both trees had been covered up in winter; but as respects the fruitful tree, the mice and rats had so gnawed the stems, that they did for them what ringing would do—checked the luxuriance, and thus the growth was more stunted and fruitful, because better hardened and ripened.

LADY-BIRDS.

Can you tell me, if I collect lady-birds now, whether I can keep them during the winter so as to breed from them next year, and turn out the produce in my orchard house? Surely something might be done in this way to rid our houses of the aphis without the use of tobacco, &c.—J. C., *Winchester.*

[We sent your note to one of our best entomologists, and in reply he says, "It is an excellent suggestion. The lady-birds

thus collected would creep into rolled-up foliage or other out-of-the-way corners, and become stationary during the winter, and be ready on the return of spring to deposit their eggs where they could find a supply of aphides.—J. O. W."]

VEITCH MEMORIAL.

Our readers would observe from the report of the preliminary meeting in last week's Journal, that the Veitch Memorial is now fairly started, and that a numerous Committee has been formed to carry it out. Formed, as this Committee is, of some of the most influential gardeners in the country, we have no doubt that when the individual members and the Sub-Committees get fairly into working order that the desired result will soon be attained. High as those names are, however, in the gardening world, they will not of themselves stimulate others to do the work. Members of Committee must take the matter in hand, and do manfully and energetically that which he whom they wish to commemorate would have done had he undertaken a similar duty. It is not enough "to lend your name." One of the most touching features of this movement is, that it has been initiated by the professional gardeners, and so generally was this desire to perpetuate the name and reputation of their friend expressed, that it amounted almost to a yearning, the numerous letters we received on the subject evidencing how strongly this feeling exists. It reminds one of the warm attachment that soldiers not unfrequently exhibit towards their general, and is, perhaps, unparalleled in the gardening world. Let us trust, then, that the work so auspiciously begun will be carried out to a speedy and successful issue.

The form which this memorial will assume is as yet uncertain. A good deal of consideration will have to be given to the question. Many suggestions have been, and, no doubt, will still be made before any decision is come to. Among those proposed at the meeting were a monument, a portrait, a medal, a prize, a Gardeners' Benevolent' pension, a club and library, a fund for disabled collectors, the education of gardeners' orphans, the erection of an Orchid house, and some others; all good in their way, and all, no doubt, the promptings of minds impressed with the importance of the subject. While the form to be adopted is yet unsettled, it may not be amiss to consider what appears to us to be the most desirable.

The essentials that a memorial ought to possess are permanence and publicity. To adopt anything that would merely last for a generation or two, or which, if it were ever so permanent, did not force itself on the public attention, in either or oth cases it would fail in the desired end. Of the suggestions that have already been made, the monument, the portrait, the medal, and the prizes, appear to contribute most towards the object, and it is in favour of these that Mr. Veitch's family are understood to have expressed themselves.

Let us consider each of these propositions singly; and first of the monument. No doubt a monument would be a very fit and proper mode of perpetuating Mr. Veitch's memory. Supposing a suitable design were obtained, where is it to be erected? If in the cemetery where Mr. Veitch lies buried, according to our idea the fitting publicity will not be obtained, and the desirable object of keeping his name prominently before the horticultural world will fail. The world moves very fast, and the greatest players are soon forgotten unless something turns up every now and then to recall them. Philip Miller, the author of the "Gardener's Dictionary," was for more than half a century a shining light in the botanical and horticultural world, a Fellow of the Royal Society, and frequently a member of its Council. His fame was so great he was styled by foreigners "Hortulanorum Princeps." A monument was erected to Philip Miller, but how many of the present generation know where that monument is? and who but for the "Gardener's Dictionary" would ever know about Philip Miller? That monument a few years ago was a mouldering stone with an illegible inscription. John Claudius Loudon a generation ago was a name familiar to every horticulturist. The man is gone, but he lives in his works; and by his works only, except to a few, is he known. Mr. Loudon has a monument erected to him, and though a generation has barely passed since his death, how many of those who now read what we have written know where Loudon's monument is? David Douglas is a name that once excited admiration and sympathy in the horticultural world. His fate shocked the feelings of the country for a while. He, too, had a monument—where is it? How often is his name heard except in the company of those who knew him? Thomas Fairchild, once a nurseryman at Hoxton, whose name the Fairchild Nectarine bears, raised his own monument when he died just 140 years ago. He left a sum of money vested in trustees, the interest of which was to be given for a sermon to be preached on Whit-Tuesday in the church of St. Leonard's, Shoreditch, "On the Wonderful Works of God in the Creation." But who knows anything of Thomas Fairchild? neither his name nor his memorial is kept fresh in the world of horticulture. Now, we have no assurance that a monument to Mr. Veitch would be more enduring than any of these, or keep his name fresh among succeeding generations.

The portrait is equally good and desirable as a monument. It must necessarily be a posthumous one. Assuming that a successful portrait of Mr. Veitch were obtained, and a suitable place were found wherein to deposit it, we think that this would fail in keeping up a constant memorial of him whose memory we love to cherish. The only permanent location would be the national portrait gallery if it could be secured a place there, and even then his name would be recalled only when future generations uninterestedly looked on the picture and read its legend.

A Veitchian medal, or a Veitchian prize, is not open to any of these objections. A medal, or medals, bearing a portrait bust of Mr. Veitch, given annually, would keep alive the name and features of him whose memory we now desire to perpetuate. The opportunities for its distribution will never fail; for horticulture and horticultural shows we shall always have with us, even to the end of time; or if these should cease, the names of those who are associated with them may fairly cease too. How or for what objects these medals should be given, we do not presume to say; these are details that may be left in the hands of those who are entrusted with carrying out the memorial. But we would advise that the sum subscribed be invested in the names of trustees who shall be appointed by the Committee, and that the annual sum arising from the investment be appropriated to the purchase of a medal, or medals, to be awarded not to exhibitors at any particular society, but wherever a worthy application of the award can be found. The medal should be given for merit of a high standard, and, like the Victoria Cross, be coveted not for its intrinsic value, but for what it represents.

All we have said on this subject is merely suggestive. Many, no doubt, will be the views taken by those who give the subject their earnest heed; but the first thing to be done is to get the money, and leave all details for the future consideration of the subscribers generally. Let all, then, do their utmost to raise a sum which will be worthy of the object, and the greater the amount subscribed the more extended and varied will be the character of the memorial.

INFLUENCES OVER THE KEEPING QUALITIES OF FRUITS.

It has been stated that there is some evidence to show that the character of one variety of the Strawberry was affected by growing in the vicinity of other sorts. Mr. Hiram Walker, of Washington County, New York, who has practised grafting since 1818, writes, that according to his experience the same thing takes place with Apples and other fruits, and he thinks the fact that some winter Apples do not keep, is not due to their being grafted on stocks of early varieties. He says he never knew any difficulty in the keeping of fruit where the orchard was all of one kind, but that when early and late sorts were all together, late fruit was rendered early, and early fruit made late, from cross-impregnation. He mentions a tree in Saratoga County which was in part grafted with a sweet variety, but the grafts bore sour Apples for several years; the grafts of the sweet Apple had been put into the lower limbs of a sour Apple tree, and as long as the upper limbs of the original tree remained, the sweet grafts bore sour fruit, from blossoms being impregnated by those on the limbs above them; when the natural limbs were removed then sweet Apples were produced. Mr. Walker mentions other instances of a similar character which have fallen under his observation. The subject is one not only of scientific interest, but of actual importance to all fruit-growers. It is within the observation of every one that a variety of fruit is not the same, even in widely separated localities. This difference is by some attributed to soil and exposure, by others to the character of the stock upon which the fruit is

grafted, and now we have the influence of the pollen of neighbouring sorts charged with being the disturbing cause. Other observations on these points are needed.—(*Utica Herald.*)

VINERY HOUSE, ALLERTON.

Lancashire, especially that part of it in which Liverpool is situated, has acquired a world-wide reputation for the excellence of its Grapes, mainly through the Garston Vineyard, the most celebrated in the world for the production of Grapes by artificial means. Besides Garston, there are other places in the neighbourhood of Liverpool where the Grapes grown, if not equalling those produced at Garston, follow at no humble distance. One of these places is Vinery House, Allerton, Liverpool, the residence of Mr. T. C. Clarke.

Vinery House is not different from many of those convenient family residences which are erected in the neighbourhood of large towns. In fact, the house is not remarkable except for this—that though built four or five years ago, owing to a family bereavement it remains almost as it was when built. Mr. Clarke was his own architect of the glass erections, and superintended everything about the place. The house seems to be built in a very substantial manner, and fitted up with every convenience. The cornices selected by Mr. Clarke for the rooms, struck me as being chaste and elaborate. A boiler in the cellar heats the conservatory and greenhouse, and there are pedestals in the entrance hall and other rooms on the ground floor containing hot-water pipes for heating the rooms. A boiler behind the kitchen fire supplies hot water for the bath room, and heats the rooms on the second or bedroom floor by means of hot-water pipes. Owing to the cause I have mentioned, the works in the grounds have not been pushed forward as they otherwise would have been, but the shrubs and groups of trees are planted and appear to be flourishing.

If there be any deficiency as regards the pleasure grounds, it is fully compensated for by the portion chiefly occupied by glass structures. It is on these that Mr. Clarke rivets his attention, everything being presided over by him, and the principal part of the work being done by his own hands. The extent of the glass must be many thousand feet, and the several structures are so lofty and substantially constructed that they must have cost a considerable sum. The bricks, however, were made on the spot, the soil being a rather strong loam with a clayey or marly subsoil, and the red sandstone underneath. The removal of the clay for making the bricks has made a reservoir for water, so that in the driest summer water is always conveniently obtained, and is ornamental besides.

The situation is generally flat, though somewhat undulating, and portions are even low. The garden, however, is on the rising ground, the dwelling on a gentle eminence, and the houses at the back of it are on even higher ground. Those for Vines are on the highest ground. The situation is so bleak that the back wall of the vineries was blown down three times whilst it was being built; but this, and other mishaps and obstacles, have been surmounted by the perseverance of Mr. Clarke, who, judging from what I saw, has paid dearly for his experience. Being a self-taught amateur, he is free from those prejudices which professed gardeners often entertain against anything new, and which cause them to pass over many things as valueless without giving them a trial. It is only those who strike out of the beaten track who attain anything grand.

The first house I was shown was a conservatory, originally intended to have been connected with the house by a glazed corridor, but this intention has not been carried out. In it were some good examples of Vallota purpurea in large pots, and there being several bulbs in each pot there were many flower stems, and the effect was very fine. This plant is not grown so much as it deserves to be. It is the best autumn-flowering Amaryllid, stands smoke well, and succeeds well as a window plant and in every greenhouse. The chief points to be attended to in order to flower it successfully are not to pot often nor remove the offsets, but to obtain a potful of bulbs. This conservatory was gay with well-grown Fuchsias trained in the form of cones 6 or 7 feet high; one of that size, Souvenir de Chiswick, was very fine, and I do not see that we have any improvement on it in the newer kinds. An equally fine plant of Sir Colin Campbell reminds one of the little advance on this presented by the new varieties we are inundated with every year. A seedling raised by Mr. Clarke, a cross between Sir Colin Campbell and Duchess of Lancaster had flowers twice the size of those of Sir Colin Campbell, with a double purple corolla and bright scarlet, well-reflexed sepals—the best double Fuchsia I have seen. The foliage, of a pale golden hue when young, is twice the size of that of Sir Colin Campbell, and more plentiful, and the habit slightly drooping and compact. This variety is very distinct, and quite an acquisition. There were also Tea-scented Roses in pots, as Devoniensis, and some China Roses; and in borders at the end, trained to the division between the conservatory and the greenhouse, as well as over the roof, were Lapageria rosea in splendid bloom, and Tecoma jasminoides, with its bright glossy foliage, and blush flowers having a crimson eye. I likewise noticed Acacia Drummondi, 8 feet high and 8 feet in diameter, and Acacia armata, 8 feet high and 6 feet in diameter.

In the adjoining greenhouse were good plants of Azaleas of such kinds as Flag of Truce, Stanleyana, &c., and Camellias well set for bloom, the foliage clean and having a bright glossy appearance. Solanum jasminoides in a border appears a good white-flowering climber, the flowers being succeeded by clusters of highly ornamental red berries.

The conservatory and greenhouse are span-roofed, and both are heated by hot-water pipes from the boiler employed for warming the mansion, which will have attached about 800 feet of 4-inch piping in addition to the connections. Along each side of these houses there is for specimen plants a stage with octagonal projections twice the width of the side stages—*i.e.*, the stage and projection are double the width of the stage where the projections do not occur, and this does away with the monotonous straight face of ordinary stages, whilst the disadvantages of a wide stage are avoided. There being free access to the stage between the projections, the plants are not so liable to be neglected in respect to watering, &c., as they are on wide stages. The stages are of stone supported by ornamental iron-work, and have a cornice or facing of iron, which has a neat appearance. The pots are placed on gravel, with which the stages are covered. The centre of the house is open, affording plenty of room to examine the plants. In the greenhouse is a tank which receives the water from the roofs; and a pump, so small that one would scarcely notice its lever-like handle—the only part visible—were it not shown, supplies the water as required. These houses are detached, and divide the pleasure grounds from the kitchen garden.

I next entered a late vinery, a lean-to, 52 feet long by 20 feet wide, but having a short back light. This house is very lofty (15 feet high), and is well ventilated at the back by a lever and crank moving the whole length of the ventilators, and in front the whole of the front lights open by means of a rack or wheel. Thus it is but the work of a moment to increase or diminish the amount of ventilation throughout the length of the house. The roof is of wood, well supported by iron, and though strong has a light appearance while, as the panes of glass are large, light is abundant. Wires are strained lengthwise of the house to train the Vines to, and it is a neater and more efficient as well as economical mode of wiring a vinery than the old plan of iron brackets screwed to the rafters, and strung with No. 6 wire, strong enough to hold a hundredweight each. No. 10 wire is quite strong enough to hold bunches of 6 or 7 lbs. weight, as may be seen here. The border is the full width of the house inside, except that there is space for a walk along the back; and in addition to the inside border there is a 12-feet border outside, the front wall being built on arches, so that the roots may pass out if disposed to do so. The border, both inside and outside, is vaulted or arched with brick underneath, and in the chambers thus formed are hot-water pipes for supplying bottom heat, so arranged that a man can examine every pipe and repair it in case of leakage. By means of side passages from the chamber communicating with the house in the back walk, perfect control is obtained over the heat in the vault or chamber; it is allowed to escape if it become too great, and it is not lost, as it warms the air of the house. Nine rows of 4-inch piping supply the top heat, and an equal number of pipes in the chamber supply bottom heat, and these, with the cross pipes and connections, give a total of 1000 feet of 4-inch piping. Mr. Clarke is in favour of plenty of piping; he likes the heat given off by pipes at a low temperature, especially for the roots, these requiring an imperceptible warmth, and not a dry, parching temperature.

The Vines were planted in 1864. The result in 1869, though not equal to that obtained in 1868, is a good crop; indeed, I think too heavy, considering the age of the Vines. Lady Downe's carries twenty-three bunches per Vine. The bunches are of good size, the berries are evenly and well set, of good size, and of a colour and bloom that would put Sloes in the

background. Here this Grape sets its bunches well, and Mr. Clarke says it is as yet the best late variety. Alicante is here larger in bunch than the Lady Downe's, fully as black, and with quite as good a bloom, but Lady Downe's has a size of berry and beauty of finish which Alicante cannot exhibit. Muscat of Alexandria is bearing an immense number of bunches, and they are not large, affording proof, if it were needed, that to have many bunches on a Vine they must necessarily not be large; though, perhaps, large enough for a gentleman's table, they would not do for exhibition. It is worth mentioning this fact, as some persons expect twenty or more bunches on a Vine, and each bunch equal to those seen on exhibition tables. You may see in every place where Grapes are grown for exhibition which are the Vines relied on. You see them with two or three large bunches, which, perhaps, may weigh a dozen pounds, and a Vine with twenty bunches in a private or non-exhibiting garden, which will weigh upwards of 1 lb. each, or 20 lbs., therefore it produces the heavier crop. The large bunches are not desirable for every-day consumption, for Grapes are never so good as when fresh cut. Mr. Clarke says his Muscats suffered severely last season from drought, and also the Barbaroesa [Gros Guillaume], which is not nearly so fine as in 1868. Having planted a number of Muscat Vines, and not finding them keep so well as Alicante, Mr. Clarke has grafted them about halfway up the house with Alicante, and on the same Vine are white and black Grapes, white at top and black at bottom. The effect is pleasing, and the object sought has been attained, as the Alicante seems to succeed on the Muscat, the bunches being fine, and the colour of the berries jet black. There is a White Nice Vine carrying two immense bunches; the size, however, is the only recommendation of this Grape.

The fourth house, and adjoining the last, is an early vinery of the same size, and the same in other respects, the border being heated, &c. It is at present occupied with Vines in pots, of which Mr. Clarke has about eight hundred fruiting canes. The Vines in pots are very strong, and promise to yield good crops next year, the wood being firm and the eyes plump. The permanent Vines are in appearance like so many bare sticks, but the eyes are so prominent, and the wood so brown and hard, that they seem prepared for the forcing they must shortly have to ripen their fruit in May. The sorts are Black Hamburgh and Golden Hamburgh. The latter succeeds admirably in the heated border, however indifferently it may do in unheated ones. Golden Champion has found a place here. Mr. Clarke has great expectations of it. He has Bowood Muscat inarched on the Frontignan, and with good results, as it ripens perfectly at that early season, but not nearly so well on its own roots, nor so early.

Leaving this house we enter the Cucumber house, at present unoccupied. It is about 12 feet wide, with a walk along the back. In front is a wide border, formed with brickwork, and having a flagged bottom; underneath is a chamber, in which are hot-water pipes for furnishing bottom heat, and to give moisture along with the heat some of the pipes are guttered to hold water, which can be poured into them from the back walk by means of an iron tube with a funnel mouth. Any excess of heat in the chamber can be regulated by means of passages communicating with the back walk, and the heated air being moist is very favourable to vegetation; besides, it serves to make up for any deficiency in the top heat. If I remember rightly, Mr. Clarke employs this house for the propagation of Vines from eyes. The three houses last named have a south aspect with a westerly inclination.—G. Abbey.

(To be continued.)

PLUMBAGO CAPENSIS.

Allow me to say a few words about a special favourite of mine, the well-known half-hardy plant, Plumbago capensis.

I wonder why it is not more freely used in the decking of gardens, for it will prosper out of doors, at least during the three summer months, and its delicate beauty, which, I think, I may call unique, more than compensates for the trouble of sheltering it before the advent of cold weather. I should be very glad to hear any details as to its propagation which the experience of others may have furnished; for, until lately, I have not had the power to do more than buy plants of it to gladden my eyes and heart. I know its capabilities are great, for I have seen it in a high state of cultivation, climbing round greenhouse walls after the fashion of Clematis Jackmanni. So zealous an advocate am I of my favourite that I would fain, perhaps in unconscious defiance of botany, transfer to it the name Agathæa cœlestis, which is bestowed on a plant with fewer characteristics (as it seems to me), suggestive of the country where nothing ever fades. All flowers are heavenly, all are endowed, either collectively or individually, with the dignity of symbolism. The fragrance of one, the purity of another, the grace of a third; the endurance, perseverance, unobtrusiveness, or majesty of many more, are palpably indicative of high and holy things; but I think no flower is gifted with loftier or more varied eloquence than the gentle Plumbago capensis. It seems the flower of truth pre-eminently. Mark its delicate transparency, its wide-open innocence, the exquisitely clear purity of its colour, pale as if in condemnation of all things exaggerated, but deepening its own sweet tint in pencillings that stream out lightwards from the flower's heart. In virtue of its long-tubed throat, the Plumbago capensis (I repeat its second name to distinguish it from P. Larpentæ), may rank among the up-springing plants, as the sweet flowers of the west wind, and all the Amaryllis and Crocus tribes; and this habit of darting upward, emulating in chastity of hue "the Shechinah of the Blue" beyond the clouds, is additionally typical of "things that are not seen." Again, the fragility of this plant's physique proclaims it to the fanciful mind a stranger in a world of storms. Among such blossoms, immortalised, we feel our beloved in the church triumphant, might fitly dwell.

The Plumbago capensis is, in point of scent, negative; but with the loyalty of an enthusiastic partisan, I declare it to be on that very account the better fitted for the work-table, the sick-room, and the various circumstances of everyday in-door life. In common with many others, I suffer physically from the near neighbourhood in rooms of the Hyacinth, Lilac, Syringa, and many of the Lily tribe. The Plumbago ministers, but never oppresses—never "makes faint with too much sweet," those who permit its presence.

My little flower garden is not much more than 20 yards square, and my greenhouse correspondingly unpretending; but I could not over-rate the joy they give me. I was incited to real labour in the sweet service of flowers partly by the example of one "Filix fœmina," whose thoughts about Ferns used to appear from time to time in this Journal; and I believe I speak the sense of all lady gardeners, when I say that none who have not personally wooed flowers can guess how gratefully they respond, nor with what full measure soothing, elevating, and delighting their cultivators. Calmly faithful always, they brighten through life our gardens, and in death our graves.—C. A. G., *Ealing*.

SEEDLING VINES.

I have more than a hundred seedling Vines raised from last year's Grapes, which have been stopped several times since they were 7 feet long, and which are many of them as thick as a finger near the bottom. Are these not unusually strong for their age? Some of them look as if they would fruit next year, but I shall not trust them. A Vine of nine months from seed can hardly be a fruiting cane, one would think.—J. R. Pearson *Chilwell*.

[There can be no doubt that the Vines are of unusual growth for their age, but being so we see no reason why they should not be allowed to bear fruit, as they would be allowed at the same age if raised from eyes. We should be glad to hear from others on this point.—Eds.]

BOTTOM HEAT: ITS USE AND ABUSE.

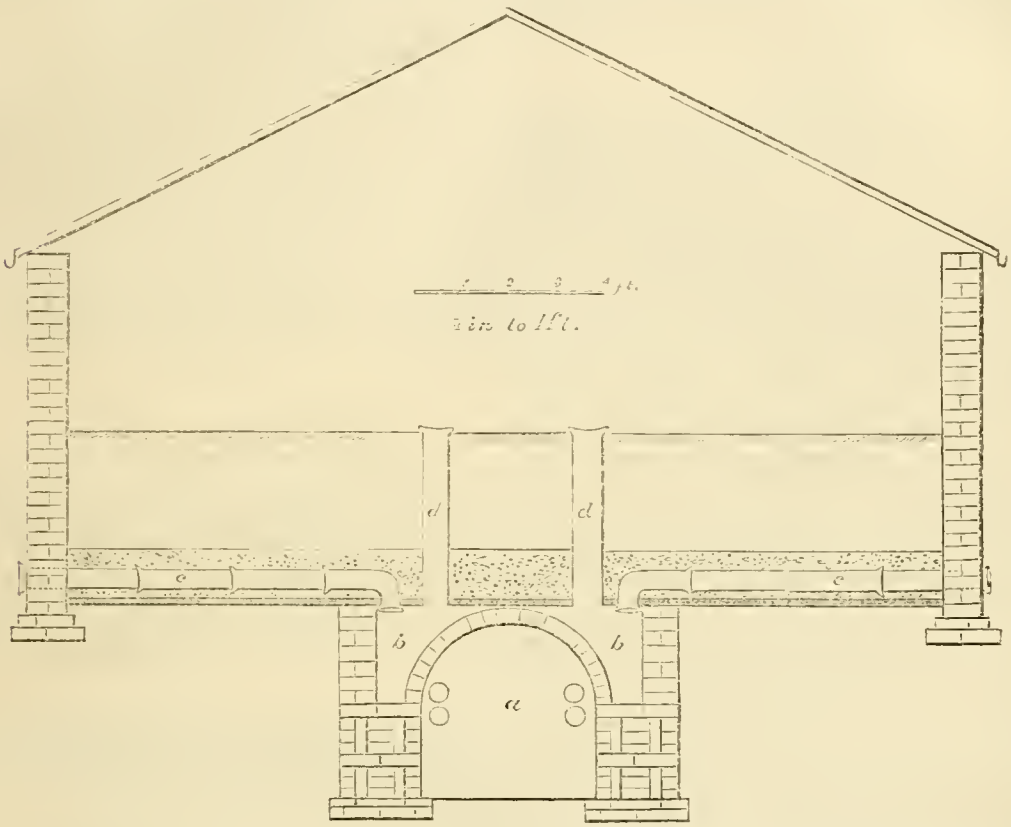
As a nurseryman, I have found bottom heat to be of the greatest use for all kinds of propagation, not only for stove, but even for hardy plants, a great many cuttings of which cannot be made to root without it. The best material for producing bottom heat for this purpose, and for forwarding young plants after they have been potted-off, is tan. It retains its heating power for a long time, and gives out just such a genial moist heat as all kinds of young plants, cuttings, and Orchids like. To keep up this genial heat, it is necessary to turn over the beds every six weeks or so, and add a little fresh tan at each turning.

The next best materials to tan are properly prepared dung and leaves; but they require so much management, and the heat is so changeable, that it is only adapted for a few plants, and requires the exercise of great care in looking after it. I now come to bottom heat

for large subjects, and for those growing in borders, such as tropical plants, Vines, &c., and it is in their case, when the heat has not been properly applied, that the abuse has been.

There has been a good deal of controversy lately about growing early Grapes without bottom heat; now, I maintain, that to have a good crop you cannot strike cuttings of the Vine without it, neither can you grow good early pot Vines without it; then why should Vines planted out in borders dislike it? My opinion is they do not, and for forcing Vines year after year very early it is positively wanted, otherwise the Vines will wear themselves out. My experience tells me that it is from the want of sufficient water that mischief arises from the use of bottom heat. I have been a victim owing to this cause, and it is scarcely possible to make men of ordinary practice believe the quantity of water that is wanted to supply a border where there is bottom heat, and in which the plants are planted out. I have now adopted the plan of measuring the water. I maintain that plants in-doors, and especially where the heat is greater, require quite as much water as out of doors; therefore I am giving 24 inches per annum, or about twelve gallons to the square foot, giving the greatest quantity when the Vines are in a growing state. I do not mean to say that even this would insure safety with badly applied bottom heat, such as from hot-water pipes amongst the drainage or in the border; there would be failures, for as regards extremes of heat and cold, and of dryness, we should be at the mercy of the stoker and waterer. In applying bottom heat to borders, it should be perfectly under control, and capable of being conveyed to the roots of the plants at will; also so that the heating medium can be extended by degrees to any distance required.

I have paid a good deal of attention to this subject, and I think the perfection of an early Grape house would be one built after the following plan:—It should have a span roof 18 feet or more wide, with arches



in the outer walls, so as to extend the borders from the inside when wanted, and also to let out the bottom heat to the outer border; in fact, to extend the roots to any distance wanted. There should be an arch in the centre, *a*, and extending the whole length of the border; the upper part pigeon-holed, to let up the heat from beneath the arch as quickly as possible to the chambers *b*, *b*, to be conveyed into the earthenware socket distributing pipes *c*, *c*, which should be laid quite level, otherwise the heat will not be regular. These pipes I recommend to be placed at intervals of 2 feet throughout the length of the house, on a concrete bottom, with 12 inches of brick rubbish over them. I have a great opinion of aërating borders for forced plants—in fact, for all kinds of plants; therefore, in a house 50 or 60 feet long I put three pipes on each side of the house, *d*, in communication with the heating chambers, so that air in winter can pass from the inside of the house amongst the roots of the plants; and when the borders are formed outside, provision can be made so that in summer they can be aërated from the outside. I think with this provision for bottom heat, air, and water, we shall hear no more of failures in forcing early Grapes.—John Standish, *Royal Nursery, Ascot, Berks.*

[The foregoing is one of the papers read at the Horticultural Congress at Manchester, but its publication has been delayed owing to the drawing not having been received with it.—Eds.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

Trench, dig, and ridge-up every spare piece of ground whenever the weather will permit. This is particularly to be observed in gardens, the soil of which is of a clayey nature. It is time to think of forcing a little *Asparagus* to come in early. The principles applied to the forcing of Sea-kale, &c., are in the main applicable to Asparagus, except that it requires abundance of air when pushing through the soil. Let all *Carrots* be taken up and stored; likewise *Beet*. A few *Parsnips* for present use may be taken up; they will, however, keep well in the ground, and thus circumstanced they may have a coat of manure spread over them for the next crop, and be trenched-out as wanted. It is a good plan to cut the head of the Carrots completely off below the neck, thus checking their tendency to grow. They may then be placed in pits like Potatoes, raising a sharp ridge over them to throw off wet. Prepare a plot of ground at once for the earliest *Peas*, by thoroughly digging and manuring it; they may be sown now while the weather is favourable. A few Mazagan *Beans* may also be planted at the same time. *Sea-kale* should now be introduced into bottom heat for the earliest supply. Those who force it where it grows may apply some hot manure round a few pots. Endeavour as

far as circumstances will permit to have a good supply of *Parsley* under protection, for there is generally a large demand for this, and in the event of a severe winter it is difficult to save it by the ordinary protection of hoops and mats. *Lettuces* and *Cauliflowers* in frames should be freely exposed on all favourable occasions. Be careful also of any *Broccoli* fit for use, or which is turning-in.

FRUIT GARDEN.

Proceed with pruning fruit trees as soon as the leaves have fallen; let no work of this sort remain till spring, which will bring its own labours. Draw out all superfluous nails and shreds, in order to furnish in-door work in bad weather. Men do little good working out of doors under such circumstances, on the contrary, often much harm to themselves and to the land by closing and hardening its surface. Look over fruit and other stores frequently, in order to see that all is safe and sound. Standard trees which have been root-pruned must be firmly secured against injury from wind; also complete any root-pruning as soon as possible.

FLOWER GARDEN.

Examine pillar and trellis Roses, and if the weather is favourable see if the soil wants to be renewed, or the kinds changed. For choice sorts, holes should be made capable of containing three or four barrowloads of well-prepared soil. Turfy loam of good quality is the chief requisite; to this add a portion of rich rotten dung, and, if at hand, a little sandy peat or leaf mould. Crocuses may be planted whenever the weather is favourable; they like a deep, light, rich, sandy soil, but will thrive in any ordinary soil or situation. In planting, the bulbs should be covered from 2 to 3 inches with fine soil, and if an effective display during the first season be desired, plant thickly, not more than 2 inches apart. For edging borders and beds the Crocus is exceedingly useful, and where planted in lines along the margins of walks, or in clumps of from three to twelve or more bulbs, and allowed to remain in the ground for several years, they produce a very pretty effect. An excellent display may be made in the flower garden in March, by each bed having a broad edging of Crocuses, the colours being nicely arranged and contrasted. This may be secured without interfering with either the spring or summer occupants, for the bulbs may be planted close to the outside of the bed, where they will scarcely be in the way either in digging or in planting. Unless the bulbs become too numerous, and the leaves cover more space than desirable, they should not be disturbed, as they bloom more profusely when well established. Care, however, must be exercised to protect them from mice, which are exceedingly partial to Crocuses, especially in winter. For blooming in-doors, either in pots or anything used instead, strong bulbs should be selected, planting them in succession, and keeping the crowns slightly under the surface of the soil. Place them in any dark, cool situation for three or four weeks to allow of their making roots before exciting them into growth. If pots are used, and doubtless these are the best if not the most ornamental, employ rich sandy soil, and secure perfect drainage, for a liberal supply of water is required during the blooming period, and if the drainage is defective, the soil is apt to become sodden by injudicious watering. While the bulbs remain in a dark place very little water need be given—merely sufficient to keep the soil, moss, or sand from becoming too dry. When the roots have made some progress the crowns will make their appearance, and as soon as these are observed, remove the pots to the greenhouse, or, where this is not convenient, a cold frame or pit will answer perfectly. Crocuses will also succeed very well in a sitting-room window; all that is requisite is to allow them as much light and air as possible on mild days, giving water as may be necessary to keep the soil in a moist state. Chrysanthemums will now be approaching perfection in most places; therefore, take every means to preserve their beauty as long as possible. For some of the most tender kinds of Roses a little protection will soon be necessary. Also plant, as previously recommended, the Briar stocks for budding upon next year, for unless these are planted before spring they seldom furnish strong shoots for early budding. With weather like the present, all new work should be pushed forward as fast as possible; and if the soil has been properly prepared by draining where necessary, as should always be done before planting, there will be fewer failures from planting evergreens now, than if the work were delayed until March. Where, however, the ground to be planted is of a harsh clayey nature, and in an unkind state at present, it will, undoubtedly, be better to defer planting until spring. Roll walks and lawns occasionally, so as to keep them firm and smooth. There will be comparatively little to be done in the flower garden at present, except sweeping and cleaning, and any spare time will be well spent in going over the stock of plants in pits for next season's use, removing every decaying leaf, and where the surface soil has become green removing it and top-dressing with sandy loam. There is nothing so unfavourable to these plants at the present season as damp; therefore, every opportunity of admitting fresh air should be taken advantage of.

GREENHOUSE AND CONSERVATORY.

Next to Camellias, Azaleas are perhaps the most showy plants that can be had in bloom early in the season; and where there is a good stock to select from, some of the most forward plants should be placed in heat soon, moistening them overhead two or three times a-day. Unless, however, plants can be had which made their growth and set their buds early, they can hardly be expected to flower so finely as under more natural circumstances in spring, and unless the buds are plump there will be some danger of the plants starting into growth instead of into flower. Dutch bulbs should be largely cultivated where a fine display is required, and where hardy shrubs are forced for the decoration of the conservatory these should be ready for the purpose. Some of the early-blooming Rhododendrons require very little forcing to bring them into blossom at any time after this season; therefore where there is a good stock of these and Ghent and other hardy Azaleas well set for bloom, a portion of the plants should be placed in heat at intervals of about three weeks, and as they are very showy and last long in beauty they will be invaluable. These, together with Camellias, Heaths, Epacrises, Acacias, Daphnes, Gesneras, Cyclamens, Cytisuses, Chinese Primulas, Cinerarias, Mignonette, tree Violets, and other plants which bloom naturally in winter, will afford a good display.—W. KEANE.

DOINGS OF THE LAST WEEK.

FROST again and continuous, not much more severe than that on the 19th, but more prejudicial to everything tender, owing to the keen stormy wind that searched through and through all tender tissues. This has left little quite green in the flower garden except Calceolarias, and even these are showing signs of succumbing. Plants of Salvia fulgens which were a blaze of scarlet, have given way before the force of the biting wind. The clear atmosphere and biting air of the afternoon before the most severe night, caused us to make preparations to meet it in most departments, and, therefore, injury has been chiefly confined to that which we left to the frost.

KITCHEN GARDEN.

Endive.—A lot of the plain and curled-leaved was protected by placing a little rough hay over it; then litter, and some branches to keep it down. Part of this is covered for blanching, and part was covered a little to be uncovered on Friday and Saturday when milder weather came. Here one fact is worth noting. For years we have used Fraser's Broad-leaved Endive, and we like it much for its compact habit, large size, and hardiness. We had such a difficulty in saving seed, as the birds would find their way under our netting, and a few pence would pay for all we wanted, that for some time we obtained the seed along with other things, and always true and superior. Whether from the ground or some other cause, whilst some pieces of this Endive are as it used to be, other pieces have leaves like parasols, and such are chiefly planted near a wall where we intended them to stand through the winter. Now, as the leaves are so large and more likely to be influenced by frost, we shall blanch and use it early. The difference in position seems to make as great a difference as between a superior and an inferior variety.

Cauliflowers.—These we had covered up as a security against frost. To save this covering-up, and also to be safer, we cut a number of basketsful of the heads becoming rather too large for the parlour, so as to give a general house supply whilst they lasted. Many more with heads the size of one's doubled fist, and close and compact, we cut over with a good length of stem, and thrust the stems into an exhausted Mushroom bed in the shed, just damping the stems as well as the earth about them, and covering the heads in very severe weather. These will supply us for some time. A fine lot with heads less than the above, and heads just forming, we took up with balls, and set them in a deep earth-pit, watering the balls as we proceeded, and leaving a somewhat dry surface. These plants

were put in slanting, and thus the leaves served to a considerable extent as a protection. These we covered with old sashes and hurdles to throw off the wet. Our great enemies, however, to this valuable crop, which we have frequently had all the winter, are mice, rats, and even rabbits. When once they taste the crisp Cauliflower heads in winter they scorn traps and baits. The best defence has been a cordon or ring of fresh tar placed thinly all round the pit, and the dose repeated as the tar dries and loses its smell. Severe weather, when covering is necessary for days, is just the time for these intruders to invite themselves to a feast.

Lettuces.—Placed a little litter over forward ones out of doors, and took up a good many nearly full grown and half grown, and gave them a similar position to the Cauliflowers. Orchard houses are very suitable for such purposes, but we shall not use ours if we can avoid it, but will try to have early Lettuce from the latest house. We also stored a quantity of Endive. We should have no difficulty with it, using wattled and thatched hurdles for protection, but for mice and rats going underneath them. We have had a hundred Lettuces and Endives rendered useless in a night, the heart being nipped out, and the large outside leaves only left. A cat, a good friend to the gardener, is quite out of the question.

Broccoli.—As soon as time can be found, we shall lay these down a little so as to cover the stems more, placing the heads to the east or the north; the leaves thus act as a protection, and in bright sun after frost, the head, if formed, thaws more gradually, and thus escapes being injured. Dwarf-growing kinds are the better of having a little litter packed about the stems. In very severe weather a little litter or fern placed lightly over them often saves a crop, and no injury is done if the covering is removed in time.

Beetroot, Carrots, &c., are now as well within doors. We think of taking up a bed of small Dutch Carrots, and placing them in sand, for soups, and the last sowing but one will stand where it is for small Carrots. Beetroot is injured if frosted much.

Peas and Beans.—The clearing-off of Cauliflower, &c., has made room for wheeling, digging, trenching, and preparing for early Beans and Peas, if to be sown at this time. As a saving of room, we think of trying a piece again, though for many years we have sown under protection in spring, and planted out, and if anything gained in time of gathering over November sowings. If we sow now we shall red-lead the seeds, and scatter the ground afterwards with our burnt rubbish heaps.

Radishes.—These are crisp where protected with litter. Younger beds had a mat a foot above them in the coldest nights.

Celery.—Besides earthing-up, we protected with long litter overhead during the coldest two nights of the week. The wind of the last night rendered the protection almost unavailing. A few large branches are good for keeping the litter in its place. Clean straw is better than litter. Had we had plenty of litter, stubble, or even dry leaves, we would have finished banking up with them, and thus have rendered protection on the top less necessary. Celery is tolerably hardy, but if much frosted on the top it soon deteriorates the plant farther down, as then the damp affects it more, and damp, on the whole, is a greater enemy to full grown Celery than even frost. Hence, though we approve of beds of Celery, on the principle of saving room and labour, we are well aware that single rows can be so treated as to be much more secure from damp. One great cause of damping, too, is growing the Celery in a deep trench. This is very useful for receiving the manure, and for giving the conditions of quick growth provided by rich soil and moisture, but these conditions are not the best for long keeping. For the latter purpose, it is better that the trench, when supplied with the manurial matter, and dug and prepared, should be rather above than below the general ground level.

Prepared for taking up Sea-kale, Rhubarb, and Asparagus. Hoed among young Cabbages, Spinach, &c., as doing so helps to keep the frost out, and we shall draw a little earth to the most forward Cabbages to prevent their being moved by the wind. The earth also protects the stems up to the leaves.

Coleworts and Savoys, especially the Early Ulm Savoy, are now in fine condition. The first may want a little protection if the frost prove severe. What a change a little frost makes to the little Ulm Savoy. It becomes exceedingly sweet when well cooked. Need we say that all frozen vegetables should be placed in the coldest water before they are placed in hot or boiling water? From want of this simple precaution, we have on great occasions seen vegetables at table that, instead of being as tender as marrow and as green as when growing, were as yellow and tough as so many pieces of dressed sheepskin. Boiling frozen vegetables is next thing to giving the partakers a dose of poison.

FRUIT GARDEN.

The odour from the leaves of Apples and Pears, made like tinder by *the frost* of the 19th, is rendering the garden anything but pleasant. A handful of leaves, when slightly rubbed in the hand, becomes a mass of fine dust. We have no recollection of having seen such a result previously from one night's frost, and especially when more tender plants, as Pelargoniums, Calceolarias, &c., escaped with but little injury. We shall be glad when these leaves fall and are cleared off, but they seem to hang firmly to the trees. The frost of this week has brought down most of the Horse Chestnut and Sweet Chestnut leaves. The leaves of the Beech were shed partly a month ago—more the result of dryness and a high wind than of the cold; and partly owing to the copious crops of Beech-mast. We never saw such heavy crops of seeds, nor yet in general such perfect seeds. With nuts and Beech-mast, we may expect that squirrels, mice, and many birds will have a comfortable time this winter. The foliage of the Ash fell very generally after the severe mornings of this week, having withstood the first frosts well. Unlike the Hazel, the Thorn, the Holly, the Beech, &c., we never saw fewer seeds or keys on the Ash than this season.

Strawberries in Pots.—Removed a few of the most forward under protection, and the bulk out of doors, we protected from the severity of the frost by laying a little straw over them. It is astonishing what a small covering of litter keeps frost from injuring plants that are close to the ground, and thus within the reach of the heat in the ground, which is prevented escaping. As Saturday threatened to be a wet day, we put the Strawberry pots down on their sides, to prevent the soil becoming soaked, as it is sure to be wet enough now. Ere long we must contrive to take the plants under protection from wet and frost, as either is apt to be more prejudicial to them than to plants growing in the natural ground.

In the wet day of Saturday employed part of our available labour in washing and thoroughly cleaning the glass, woodwork, stages, &c., in a vinery, preparatory to filling it with plants; going through much the same process, in the way of prevention, as lately described for the Peach house. More hands would have been set to this work, but we were anxious to take up a number of bedding Pelargoniums, and store them in little room.

We looked over the *Grapes* in the late vinery for a damp berry here or there, and gave a little fire heat, chiefly during the day, to keep the air dry and in motion. The Vines in the orchard house have had discoloured by frost the foliage that came against the glass, but these leaves and some small laterals we shall let alone, as they will furnish some protection to the Grapes. We put a fire in an iron stove in the coldest nights, and it has kept the house safe and without a damped berry. Owing to the large squares of glass the wood is hard and well ripened. The Grapes will be useful to us in November and later. A good many border plants are in this house, but as little water as possible is given to them. These plants are in, because we were afraid that 10° of frost might mount up to 20°, and as they stood in a house where there was no stove, and therefore might have been injured. The other house when the leaves are more loose, will do for a lot of Strawberry pots. We put a few Chestnut leaves and some litter on Vine borders, to prevent their being very much cooled by the frost.

ORNAMENTAL DEPARTMENT.

Much of the work here has been incidentally alluded to. We merely finished putting in Calceolaria cuttings and filled some lights with Neapolitan Violets, lifting them with balls, nipping off every bit of runner, and placing them firmly near the glass in rich, light, fibrous loam, with some sweet rotten dung and leaf mould beneath. We were gathering Violets—viz., Russian, Czar, and Double Blue rather freely out of doors, but the frost has checked them, and even what flowers show have little or no scent. We are inclined, next week, to lift enough of these sorts to fill two or three lights of a frame or pit, so as to be more independent of the weather, as by clearing the vinery thoroughly we may make room for this purpose.

Scarcity of room prevents the faculty of scheming and contriving from ever getting comfortably moss-grown; but scarcity of room under glass, or out of doors, often greatly increases labour in moving, &c. There are but few common gardens

where the old adage can be carried out, "A place for everything, and everything in its place." The manager must contrive a place for many things, and many things in a place, and these shifted and changed very often, whilst a constant struggle must be maintained as to the space to be given to what ministers to the senses of sight and scent, and those which appeal chiefly to the, perhaps, more gross sensations of the palate. Hence a large garden, with a place for everything, and one crop of one thing chiefly in the one place at a time, may be managed with less labour than a much smaller garden with less conveniences, but where something of the same results are expected, and which can only be partly realised by a well-considered system of shifting and moving, which cannot be done without extra labour. Looked at in this light, a small place, though involving less outlay at first, may become much more expensive in yearly outlay than a larger one. Mere size of houses or ground, which some of our readers seem to look upon as everything, in reality forms only one item of comparison as to outlay, even so far as mere labour is concerned. The procuring of, and the proper attending to, rare and costly plants is quite another affair, in which keeping-up one acre may cost more than a dozen acres where no such tastes are indulged.

Depending chiefly for next year's display on young *Scarlet Pelargoniums*, now standing thickly in boxes—that is to say, with 1½ or 2 inches between plant and plant, we, nevertheless, on the afternoon before the sharpest night took up a good many old plants, and placed them in sheds, and out of doors covered over with litter. Some of the most tender of these, as variegated kinds, we potted separately in small pots, without any pruning, except removing a few of the larger leaves, and set in a little bottom heat to root quickly, whilst the tops are kept airy. Others with plain leaves we deprived of all the large leaves, all larger than a sixpence, at the points, and only shortened the larger shoots; these we packed like so many faggots—ten, twelve, or twenty in large pots and boxes; they will come in for centres and particular purposes when separated next season. Others, again, had their roots shortened, the heads pruned-in rather closely, looking when cut like so many small antlers of deer, every leaf removed, the cut points dipped in lime and charcoal, and packed as closely as they would go together. A good-sized pot, or a small box, would hold from a dozen to a score. These, watered, allowed to drain, then surfaced with dry soil, and placed anywhere secure from frost and damp, even though there be little light, will be all safe, and begin to break afresh about March. As soon as the young leaves show, the plants will want light; and when the leaves become crowded the plants must be separated, and fresh potted or planted. There are few of the Scarlet group which will not do well under this treatment. Every cottager who loves the bright scarlets, may thus preserve his plants in a dry cellar or garret in winter, have them singled out in his windows in spring, and planted out in May. By the plan first referred to—retaining most of the roots and most of the stems, but removing all the leaves, he may keep a dozen large plants in a pot in winter, but they need light, as in his window, or the stems will be apt to decay and shrivel. These plants, preserved in either way, generally bloom more freely early in the season than younger plants, but they do not continue to flower so well late in autumn, unless they receive a little encouragement from a little mulching in summer.—R. F.

COVENT GARDEN MARKET.—November 3.

The improvement noticed last week is barely kept up, but we may reasonably expect it to remain as it is, if it prove no better. Foreign Pears are not so freely offered as they were, but other produce is about the average. Potatoes are plentiful and good.

TRADE CATALOGUES RECEIVED.

J. Linden, Jardin Royal de Zoologie et d'Horticulture, Quartier Léopold, Brussels, and 52, Rue du Chaume, Ghent (Etablissement Horticole Ambroise Verschaffelt).—*Supplément et Extrait des Catalogues Généraux, No.* 83.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*A Subscriber, Manchester*).—Keane's "In-door Gardening" and "Out-door Gardening." You can have the two volumes, post free, if you enclose forty postage stamps with your address. (*R. King*).—We recommend to you "Flower Garden Plans." It contains directions for arranging and cultivating flowers and shrubs. You can have the volume post free from our office if you enclose sixty-four postage stamps with your address.

Memorial (*T. S.*).—It would be very invidious to oppose the friends of any man testifying respect for his memory. You are wrong in observing that Loudon and Beaton had no memorials. The debts of the first were paid off by subscription, and a monument to his memory erected in the Kensal Green Cemetery. We and a few other friends erected a tombstone in Surbiton Churchyard to the memory of Mr. Beaton.

Woolly Excrescences on Apple Trees (*Glenageary*).—These, and the red-juiced insects beneath, are the American Blight. Apply to all the places spirit of turpentine and soft soap with a hard brush. In the winter any surviving insects will descend to the roots of the trees. Remove some of the earth from over the roots as the spring approaches, say in February, and soak around the stem with ammoniacal liquor from the gas works.

Laxton's Supreme Pea (*T. Parke*).—We cannot insert any more letters on the subject. The communications of "J. W." and Mr. Laxton place it in the true light. The Pea is good, but not a dwarf.

Vines on Back Wall of Vinery (*F. W.*).—No Vine will do well, as the back will be so much shaded. We have ripened Black Hamburghs, however, on such a wall by training the rods down it of the Vines planted in front, and that extended beyond the roof. You may have a straw-coloured Rose, but not a deep yellow.

Vines (*J. K. Boyd*).—We would advise you to put Mrs. Pince in your early house. The other is a first-rate Grape, but would do better in the Muscat house, and it hangs about as long as the Muscat. It is quite new, and was introduced since the last edition of the "Fruit Manual" was published.

Vine Leaves Blotched (*A. B.*).—As the roots are in an outside border, and the Grapes shank, we have no doubt that the roots are too cold at times, and too dry at others. If the border were covered to keep out frost and excessive wet, and mulched in summer to prevent excessive dryness, you would probably ward off the diseases of the fruit and leaves.

Caterpillar (*C. Marsden*).—Owing to our unavoidable absence, the caterpillar was dead, and shrunk up so much that we could not identify it.

Seedling Verbena (*S. Shepperson*).—It is too late in the season to form any opinion of your seedling Verbena; it appears to be of strong habit, but nothing can be said of the colour so late in the year.

Carnations and Picotees (*Picotee*).—The soil seems too poor; to three parts of such soil add one part dried cowdung, and one part vegetable mould, such as decayed leaves or the bottom of an old woodstack. We could detect no insect but a mite or Acarus, and that does no harm.

Seedling Apple (*W. Wilson*).—Unfortunately your seedling Apples, Lady Louisa Egerton, were quite musty from being packed in moss.

Roots Storing (*C. Ellis*).—Beetroot will keep well in a cellar or vault, if stored in dry sand in boxes, or placed in alternate layers with sand. All kinds of roots keep well in this manner.

Blanching Chicory (*Idem*).—It blanches readily when taken up, the tops cut off, and the roots placed rather thickly in a box in damp, but not wet, soil. If placed in a dark cellar it is not necessary to cover it, but if the place is not dark the roots must be covered. A temperature of 55° is necessary to have it crisp and tender, and not bitter. If grown in a cool cellar the leaves are tough and bitter. We have not found mice interfere with it; but if they do, trap them by means of a brick or figure-of-4 trap baited with a bean.

Rhopala corcovadensis Growing too Large (*Sigma*).—Next February we would cut the plant down to within a few inches of its base, and it will, no doubt, start strongly. The parts cut off may be made into cuttings, inserting them in sandy soil, and placing them in brisk bottom heat.

Melons Infested with Thrips (*A Disappointed Melon and Cucumber Grower*).—Densely fill the house with tobacco smoke, choosing a calm evening and shutting the house up closely, taking care to have the foliage of the plants dry, and to deliver the smoke cool. Fumigate on alternate evenings, and again as occasion requires. The house must have been kept much too warm and dry, if thrips attacked the plants as soon as the fruit were set. Keep a moister atmosphere, and well supply the plants with water at the roots. After fumigating, on the following day keep the house as close and moist as the weather will permit. The quantity of tobacco paper you name is quite inadequate to fill the house with smoke for the destruction of thrips, and it should be of the best quality. Fumigation is of no use unless the house be quite filled with smoke.

Making Mushroom Spawn (*Idem*).—If you have no experience in making it you had better purchase what you want from some seedsman. Making small quantities of it does not pay. No better time for making the spawn can be fixed on than the end of August and the month of September. Take, as materials, a barrow-load of cow dung, rather stiff, and two barrow-loads of horse-droppings, with a little short straw with them, and half a barrow-load of fibry loam. Mix these up into a stiff mortar-like substance until it is pretty well incorporated and looks like grafting-clay. Then make a frame either of iron or wood, say half-inch boards if the latter, and in four pieces—that is, two sides and two ends, enclosing a space of 9 inches long, 4½ inches wide, and 1½ inch deep. Then obtain a flat clean board, and a bucket of water, dip the frame in the water, place it on your board, fill it with the prepared dung, strike level with a spade or trowel, and turn out the brick on boards, to dry on its flat side. In a couple of days make two holes in the brick, but not going through it—say three-quarters of an inch in diameter, turn the bricks until they are tolerably dry, then into each hole push a piece of good spawn, and draw a little cowdung or clay over it to prevent its falling out. Next make up a slight hotbed of litter, on which build these bricks in open honeycomb or pigeou-hole fashion, and cover over with litter, so that these spawn bricks shall have a temperature of from 80° to 85°, and not more. As the spawn runs, the bricks must be examined, and as soon as they are filled with the gossamer-like white spawn threads, they should be removed, and kept in a dry place until wanted for use. Some bricks or pieces will be ready to remove before others.

Grafting Orange Trees (*A. B.*).—Having no heat and no means of giving any, we should advise your obtaining a plant of the Mandarin Orange, and, raising the latter to the height required, inarch the stock with it. This may be done at the end of March or beginning of April. We do not think you will be successful in any other way without heat.

Stocks for Apple and Pear Trees (*Idem*).—The French Paradise is the best stock for the Apple on light sandy soils, the situation being warm, otherwise the English Paradise stock is to be preferred. On the Pear stock Pears succeed in such a soil with rich surface-dressings, and so do those on the Quince. The free stock is to all intents the Crab, being the plants from the pips of cider Apples. Pear free stocks are from the pips of Pears, chiefly those used in the manufacture of perry.

Sphærogyne latifolia Leafless (*Amateur*).—We are unable to account for the plant losing its leaves. We would keep it rather dry during the winter, giving no more water than enough to keep the wood plump. From this time to February it should have a night temperature of 55°. In February increase the temperature to 60° at night, and to 70° or 75° by day, and if you have a hotbed affording a heat of 70° or 75°, plunge the pot in it to the rim, and give a slight sprinkling with water twice a-day until the plant begins to grow; then discontinue the sprinkling, but maintain a moist atmosphere by frequently sprinkling the paths, walls, &c. If the plant is straggling cut it down to within two or three eyes of the bottom, and put in the top. It will strike freely in sandy soil in bottom heat if covered with a glass, and will make a better plant than the old one. When the plant begins to grow shake it out of its pot, removing the ball considerably, and place it in a pot no larger than sufficient to contain the roots. Return it to the hotbed, or keep it in the warmest part of the house, shading from bright sun, and keeping close and moist. Be careful not to overwater; indeed, water sparingly until the roots are working freely in the fresh soil. Shift the plant into a larger pot as required, and it will, if all go well, be a good plant and require a large-sized pot by June. A compost of one-half fibrous loam, one-fourth sandy peat, and one-fourth leaf soil, with a free admixture of sand will grow it well. Good drainage is necessary. Allow plenty of room, and do not let the sun strike powerfully on the leaves whilst wet, or they will spot. A temperature of from 65° to 70° at night, and from 75° to 85° or 90° by day with sun and air, is suitable in summer.

Azaleas Losing their Leaves (*Buxton*).—We think your plants have a defective root-action, occasioned by imperfect drainage and want of water in summer, or they are kept too warm and dry. The shoot sent is perfectly healthy. Keep it cool and give an abundance of air. Do they not require repotting? The wood is weak. Azaleas often lose many leaves, some years much more than others, and some kinds have a tendency to do so, frequently starting into premature growth. We think it is frequently caused by keeping the plants too long in heat. The wood then ripens prematurely and the leaves fall.

Earth Round the Stem of Quince Stock (*F.*).—Pear trees on Quince stocks twenty years old, planted as directed in Rivers's "Miniature Fruit Garden," the stock covered up to, but not over, the junction of the bud with the stock, are still flourishing. It is quite probable that the upper roots from the stock may weaken the lower ones, but if so, the health of the trees has not suffered. It should be the aim of all good cultivators to encourage the surface-rooting of fruit trees. There are no "two sets of roots" formed by the Quince stock, the lower ones in various soils may be less active than those near the surface.

Monstrueuse Nectarine (*C. R.*).—Many years ago Mr. Rivers received it from France, but does not mention it in his catalogue because he does not cultivate it.

West Indian Seed (*T. G.*).—We cannot name plants from their seeds.

Cucumbers Gumming (*W. L.*).—We are unable to account for the gumming of the fruit; but attribute it to the richness of the soil. Most soils are sufficiently rich without an addition of one-third of rotten dung, especially for winter crops. We are strengthened in our opinion by the fact that your plants do not gum in spring, when the sap, from the increased sun heat and light, is better elaborated.

Show and Fancy Pelargoniums to Bloom in May (*W. A.*).—The plants, we presume, are in small pots, and near the glass in a cool airy house. If the shoots are more than 3 inches long, pinch out their points, and peg down or otherwise tie the shoots, but without stakes, so as to clothe the pot to its rim, disposing the shoots equally so as to form a compact plant. Shift the plants into larger pots in December, but if already in good-sized pots they may have their final shift in January or the beginning of February, when they should be put in their blooming-pots. The stopping may be continued as required until the beginning of March, but not afterwards. Liquid manure should be given from March.

Storing Dahlia Tubers (*M. T. M.*).—Take them up after the first frost, and put them in an airy place for a few days until dried; then store them in any dry and cool place from which frost is excluded. Dry sand is the best material to place them in.

Culture of Brunsvigias (*Rush*).—Keep them cool and dry during the winter, and in a light airy position. A greenhouse is sufficiently warm. Potting in March is probably the cause of the leaves turning yellow. To make them flower freely they should be kept pot-bound. Water should be freely given when the plants are growing, accompanied with considerable atmospheric moisture, and when a good growth is made give no more water than enough to keep the leaves from flagging. Never allow the soil to become dust dry.

Pelargonium for Conservatory Wall (*Idem*).—Bridesmaid is a good strong-growing sort; but Clipper, with large fine trusses and scarlet flowers, is better for flowering, though not so vigorous in growth.

Red Camellia for Conservatory Wall (*Idem*).—As you do not care for either rarity or novelty, but vigorous growth and brilliancy of bloom, Reticulata, a semi-double red, would suit; but Bealii, or Leeana superba, has a better flower.

Stopping Cinerarias (*Idem*).—You may delay the flowering of Cinerarias by pinching out the points of the flowering shoots when a few inches high. They ought to be pinched to within two or three joints of their base.

Anthurium Scherzerianum Potting (*W. E.*).—The pot should be filled one-third of its depth with crocks for drainage. For compost, use one-half fibrous brown peat, one-fourth turfy loam, torn in pieces by the hand and used rather rough, and one-fourth of old dry cow dung, with the addition of one-sixth of silver sand, and one-sixth of charcoal in pieces between the size of peas and hazel nuts, well mixed and carefully placed amongst the roots. The soil should be raised in the centre of the pot. The roots should be only just covered. The pots have a neat appearance when surfaced with live green moss. The night temperature should be from 60° to 65° in winter, and from 65° to 70° in summer; the day temperature may be from 70° to 75° in winter, and from 80° to 90° with sun and air in summer. On dull days an increase of from 5° to 10° on the night temperature is sufficient.

Trichinium Manglesii Culture (*Idem*).—The seed should be sown in April, and the plants forwarded in a hotbed until of good size, and then hardened-off and removed to a greenhouse to bloom. Sandy loam enriched with well-rotted manure, and one-third peat, will grow them well. The treatment does not differ from that of half-hardy annuals bloomed in a greenhouse.

Climbers, &c., with Scarlet or Orange Berries for South and West Walls (*J. W.*).—Cratægus pyracantha, Cotoneaster Simmonsii, C. microphylla; and Lonicera Periclymenum belgicum, flexuosa, and floribunda, have orange berries and sweet-scented flowers.

Salting Asparagus Beds (*J. L.*).—Now is not a good time to salt Asparagus beds. It is best applied in March. For a bed 22 feet by 4 feet, 14 lbs. of salt are a good and sufficient dressing.

Rose Stocks (*Idem*).—The Manetti stock is of Italian origin, deriving its name from Signor Manetti. It is not in any way allied to the English Briar. The Céline stock is a vigorous-growing kind.

Gladiolus Bulbs after Flowering (*H. J.*).—Gladiolus bulbs, taken up when the flowering is over, ought to be well dried, and kept in sand in a cool dry place until March; they should be kept secure from frost. Those planted in autumn will only need to have a mulching of partially decayed leaf mould. In stiff heavy soils, however, the bulbs are best taken up.

Removing Pampas Grass (*Idem*).—Large plants of Pampas Grass ought not to be removed until the end of March or the beginning of April, or about the time they are commencing to grow. Unless moved with good balls, and liberally supplied with water in dry weather, they will next year flower very weakly, or not at all.

Potting Belladonna Lilies (*Idem*). — The bulbs may be potted as soon as the growth is complete, or at the end of May or beginning of June. For single bulbs the pots must be small.

Iris pavonia Culture (*Idem*).—This may be treated like Hyacinths, plunged in ashes until new roots are formed, and then placed in a light airy greenhouse. The ashes of burnt sawdust are a good plunging material.

Hyacinths in Glasses (*Idem*).—These should remain in the dark until the roots reach the water, and have extended to a considerable length. A month or six weeks are usually required.

Plantain on Lawn (*W. P.*).—There is no mode of destroying so effectual

as eradicating the plants by scooping them out with a knife; a pinch of common salt inserted in the vacancy made renders the destruction doubly sure. If there are any bare places visible where the Plantain was, put in them a little fresh soil, and sprinkle a little seed of Suckling, Trifolium minus, in early spring.

Early Potato (*A Monthly Reader*).—Myatt's Prolific is a good early Potato, but all early Potatoes are firm and waxy until mature. The best of all Potatoes for mealiness is the Lapstone, but it is not a first but a second early.

Removing Fruit Trees (*Idem*).—If removed now with good roots, shaking off no more soil than is unavoidable, they will fruit next year, if furnished with fruit buds. After their removal, mulch the ground with 2 or 3 inches thick of littery manure to about a foot farther from the stem than the roots extend. Water next spring and summer in dry weather.

Wintering Coleuses (*Constant Subscriber*).—To winter them safely, the temperature should not be less than 45° at night, and no more water should be given than sufficient to keep the leaves from flagging. Light loam with a little leaf soil is the most suitable compost. The causes of your plants damping-off are most likely the atmosphere being too moist and cold, and too much water being given at the roots. Let them have the warmest and lightest part of the house. The best way to winter them is to have cuttings struck early in September, to pot these singly when rooted, and grow them in a cool stove with a temperature of 50° to 55° at night, and 60° to 65° by day, or more from sun heat. They should be kept near the glass. They will thus be kept slowly growing during the winter.

Boiler on the Surface (*S.*).—Your chief difficulty would be with the nearness of the water to the soil's surface; but you may do much by raising the pipes a little inside the houses to be heated. It is well to have the boiler sunk, but if the main flow pipes are only a little above the top of the boiler, the circulation will go on well enough. Keeping this in view, any boiler will do if the top of the boiler be lower than the heating pipes; a few inches will do. The most shallow boilers we have seen are such as are made by Mr. Hughes, of Bishop Stortford, for Mr. Rivers's brick Arnott stoves. These, 16 inches square, are slightly saddle-backed, the ends being 4 inches deep, and the centre 2 inches deep. These boilers could be set on the top of a furnace a foot deep, and with the heat to play over them, and thus, with a small ashpit, you could manage without going down to the water level. Nothing could be simpler. To heat 400 feet of piping, we would recommend a boiler 24 inches square, or longer by less in breadth. These must, however, be fed from below. To feed at the top, as you require, a cylinder boiler will be best, such as a cast-iron one 24 inches in height, and 20 inches in width. An ashpit of 9 inches would be required, but the top of the boiler might stand above the ground level if the pipes in the house rise a little rather than fall. Either of these plans would keep you above the 8-feet water level.

Various (*F. G.*).—There is no separate work on the culture of Succulents. The Echeverias are not difficult to winter if taken up early, and established before dull autumn weather sets in. It is the dull, damp weather we have in autumn that is so injurious to them, by causing succulency of growth. A poorer soil and drier atmosphere are what they require. Sonchus macranthus is only hardy in the south of England in warm situations and well-drained soil. Hardy shrubs of scarce kinds are best kept in summer with the pots sunk in the open ground, covering the rims about an inch deep. It is better than planting out, as pot plants are more safely removed in autumn.

Raising Fuchsias from Seed (*A Cottage Gardener*).—The pods should remain on the plant until they fall off, then place them on a shelf for a few days, and squeeze and wash the seeds from the pulp, spreading the seeds on paper thinly, and when dried, storing them in dry paper. In February or March sow the seeds in a compost of two parts sandy loam and one part leaf soil, making the soil very fine at top, and just covering the seeds with very fine soil. Give a gentle watering, and place the pot in a hotbed, keeping the soil just moist. When the seedlings are large enough to handle, pot them off singly, and return them to the hotbed. When established harden them off and remove them to a greenhouse. If you have no hotbed or greenhouse, the seed may be sown in a pot and placed in a warm window. Germination will be slower, but plants may thus be raised.

Standard Apple Trees (*Edmund Jenner*).—If you intend the trees to remain as standards, you must just shorten the branches about one-third, and make them grow bushy instead of lanky, and perhaps by the time they have made a good head they will have exhausted their excessive vigour. If you would convert them into pyramids, cut off their heads and cause shoots to be developed all over the stem, which, when they have made a good growth, may be shortened back to induce the production of laterals.

Indianarubber Plant Cutting down (*Wyeside*).—The plant which is too tall, may be cut down in February or March to within a foot of the soil, but we cannot guarantee that it will not bleed, though we do not apprehend any great injury to the plant from the bleeding. The parts cut off may be inserted as cuttings; and from eyes the plant may be propagated in brisk bottom heat.

Late Pears (*Idem*).—We have found the following good from a west wall, none of those you name being good except from trees in the open ground. Beurré d'Aremberg, Glou Morçeau, Thompson's, Joséphine de Malines, Bergamotte Esperen, Ne Plus Meuris, Winter Nelis, and Knight's Monarch, are all good, and in use from November to March. We cannot tell your Pear from the description and outline. Send us a specimen.

Names of Fruits (*E. W.*).—Both Pears are the Winter Bon Chrétien. The Apple is Golden Knsset. (*An Old Subscriber*).—The specimens are so small it is not easy to recognise them; but we think that No. 1 is Benrre de Rance, and 2, Knight's Monarch. (*S., Guernsey*).—Golden Reinette. (*N. F. H.*).—1, Conseiller de la Cour; 2, Nouveau Poiteau. (*Crofts*).—*Apples:* 1, Lewis's Incomparable; 2, Beauty of Kent; 3, Dumelow's Seedling; 4, Autumn Pearmain. *Pears:* 1, Comte de Flandre; 2, Doyenné Musqué; 3, Duchesse de Brabant. (*C. Marsden*).—The two Pears were so decayed we are sorry we could not identify them. (*Centurion*).—4, Ne Plus Meuris; 5, Beurré Diel; 6, very like Beurré d'Amboise; 7, is correct, it is also called Tardive de Toulouse; 9, certainly Nouveau Poiteau; 10, Adams's Pearmain; 11, Herefordshire Pearmain; 12, Brougham. We shall keep the others and endeavour to discover their names. (*J. T.*) —1, Vicar of Winkfield; 2, Beurré Diel. (*D. W. H., Crieff*).—1, Triomphe de Jodoigne; 2, Glou Morçeau; 3, Easter Beurré; 4, Duchesse d'Angoulême; 5, Beurré Nantais. (*W. B., North Wales*).—1, Conseiller de la Cour; 2, Beurré d'Aremberg; 3, Glou Morçeau; 4, Easter Beurré; 5, Broompark; 6, Beurré de Rance; 7, Passe Colmar; 8, Beurré Diel; 9, Van Mons Léon le Clerc; 10, Winter Nelis; 12, Hampden's Bergamot; 13, Golden Winter Pearmain. (*K. B. M.*).—*Pears:* 1, Nouveau Poiteau; 2, Belle de Noël; 3, Napoléon; 4, Van Mons Léon le Clerc; 6, Beurré Diel; 7, Old Colmar; 8, Arlequine Musqué; 9, Easter Beurré; 10, Chaumontel. *Apples:* 1, Margil; 3, Grange's Pearmain; 4, Golden Winter Pearmain; 6, Tower of Glamis; 7, Wormsley Pippin; 8, Golden Harvey; 9, Yorkshire Greening; 11, Franklin's Golden Pippin. (*G. W.*).—5, Kingston Black; 6, Golden Winter Pearmain; 8, Adams's Pearmain. The others appear to be all local sorts, with which we are unacquainted. Only two Pears arrived, and we can identify neither. (*G R. C. C.*).—1, Léon Grégoire; 2, Beurré Amande; 3, Bon Chrétien Fondante. The Apple is the Autumn Pearmain. (*C. A.*).—1, Thompson's; 2, Doyenné Gris; 3, Suffolk Thorn; 4, Beurré Diel; 5, Winter Nelis.

Names of Plants (*Northwich*).—1, only leaves; 2, Pernettya mucronata; 3, Cassiope ericoides. (*J. Hill, Queenstown*).—1, Æschynanthus purpurascens; 2, Begonia maculata, also known as B. argyrostigma; 3, Begonia incarnata, also known as B. insignis; 4, Bouvardia splendens; 5, Eccremocarpus scaber, otherwise Calampelis scabra. (*G. W. A.*).—One of the hybrid Veronicas near to V. Andersonii. Give greenhouse treatment. (*J. J. D.*).—A Canna, apparently one of the hybrids now used for subtropical bedding, but we cannot say which from the specimen sent us. Most probably the rhizomes will bear the winter, if mild, uninjured, especially if covered with litter. (*M. H.*).—1, Aster Novi-Belgii; 2, A. Novæ-Angliæ; 3, A. laxus; 4, A. cyaneus.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending November 2nd.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, AND PIGEON CHRONICLE.

A BUNCH OF FEATHERS.

Rather more than six years ago I began poultry-keeping, moved by the pleasant articles with which your Journal abounds. At the same time you courteously published some strictures of mine on certain improprieties connected with the entrance of a few exhibitors and others to the Birmingham Poultry Show before the general public were admitted, and before the judging was over. It is a coincidence, as I am giving up poultry-keeping from want of time and room, but not from my interest in poultry and in poultry-keepers waning, that in my own neighbourhood a similar impropriety should have called forth a like condemnation. Your Journal has already expressed disapprobation of such proceedings. This is enough. Let bygones be bygones, and let us hope that the offenders will amend.

Your correspondent, signing himself "Justice," in the Journal of October 21st, opens several questions, however, with regard to poultry shows and their committees generally, which must not be passed by if poultry-showing is to be the amusement of ladies and gentlemen who are disposed to use the shows for other purposes than pecuniary gain.

During the six years which have passed since I began poultry-keeping as an enthusiast, I have gone through the different stages of exhibitor, amateur dealer, experimentalist in food and housing, and in breeding for feather and for flesh. I have read nearly all that has been written in that time about poultry, and I have listened to much that has been said. I have seen the Poultry Club rise and fall, the National Poultry Company and others of its kind blown away like bundles of feathers. Speculators, who have gone in for poultry farms and poultry appliances and machinery, which almost offered to supersede Nature, have one after the other passed away. Large breeders for food and for fancy, of wealth and title, have one after another ceased to be, and changes innumerable have, in the ordinary course of things, from time to time taken place. Other men have seen the same, and, perhaps, more than I have; but many have not noted these things, and, if they have noted them, have not brought their conclusions to light. It is in the hope that I may stir up others more capable than myself to the examination of questions connected with poultry-keeping that I write this preliminary letter. I hope to be permitted to follow it by others dealing with the questions of poultry shows, the breeding for fancy and for food—the latter a point so important, that every experience which can be given is of inestimable value, whilst it is all to be desired that statements should not be allowed to go forth which are fallacious, and would be necessarily detrimental to the one great point to be kept in view—namely, the rearing of poultry on farms as an important part of the food of the people —Egomet.

OUR POULTRY SHOWS.

Under this head appeared an article in "our Journal" of October 21st, signed "Justice," in which he complains of one or two fancied evils, "which, if unchecked, must ultimately destroy much of the popularity of our poultry shows." The first is, "secretaries and committee even competing for prizes;" and the second is, "local exhibitors being allowed to compete with the same birds for both local and general cups."

"Justice" does not state in what consists the first evil, from which I infer it must be so patent to his imagination that he thinks it must be perfectly obvious to others. I cannot see any evil in the practice, but only good. Why, who are the secretaries and committeemen of our shows? Enthusiastic fanciers, who are willing to spend and be spent for the benefit of their particular hobby—men who, being for the time semi-lunatics, on their first committee-meeting dip their hands deep into their pockets, and at their last meeting repeat the operation, only sometimes a little deeper than before. They are men who will give much valuable time, make great sacrifices, go through a deal of hard work, which, from the time of receiving the first to despatching the last package of birds, is work. They are men who will leave their drawing-room to blister their fingers with boxes and hampers, and pens, and cages, and rope, and string, and canvas, and packing needles—aye, and I have even seen a lady writing out "copy" of a heavy catalogue for the printer; folding and addressing the early editions, that expectant exhibitors might know their success by breakfast time next morning; and then winding up the labours of a severely exhausting week by plying her packing needle in a way which has evoked many a letter of thanks from rough honest men, whose birds have returned to them so tenderly cared for. Our secretaries and committeemen are men whose constant study it is to give to all a "clear stage and no favour," to effect which, and to avoid the very appearance of evil, is their greatest anxiety. They are men who ought to be above suspicion, or they are not fit for their office.

And why all this labour and expense? Is it simply to bring birds from a distance to compete for their prizes? By no means. It is primarily to encourage the breeding of various races and the development of their beauties—to add their little effort to the other little efforts which are made throughout the country, and without which there would be no shows. But it is also that they may bring a great show home to their own doors, where they may measure with their own eyes the produce of their own yards, their own aviaries, their own hutches, their own kennels, against those of their friends afar off. And on what tangible grounds can anyone say Nay? I ask "Justice" in the name of everything that is chivalric and honourable, Why not?

Nor can I see any evil likely to result from the second complaint. Supposing a society, in addition to an open cup, should offer a local cup. I think I am right in saying that in nearly every instance this is done on the assumption that the local man has but a small chance with the outside competitor; but it affords him an opportunity of competing among his fellows for a trophy which the foreign exhibitor cannot touch—it is far beyond his reach by being made local. But because there is an additional incentive in the shape of a special reward to him who comes off best in this unequal fight, that should not debar the local man from aiming at the great prize of all. And if by virtue of his superior prowess he should in the race beat the whole field, who could begrudge him his double honours? I am quite open to admit that in offering a local cup the contingency I have supposed is not contemplated and will not often occur; in fact, its frequent repetition would defeat its original intention, since it would demonstrate that those at home were on an equality with those abroad, and hence the local cup would be abolished. So long, however, as a society chooses to offer a special reward to him within its limits who can deal the hardest blows at the expected foe, I cannot see why he should lose that reward because he absolutely fairly vanquishes his enemy and wins his armour.

"Justice" has nothing to do with what Long Sutton or any other society chooses to offer its members. It offers a prize open to the world, for which "Justice" can compete if he think fit, and the presence or absence of a local incentive will not impoverish him, or militate against his chance of the prize for which he enters. He has nothing to do with the local prize any more than if it were not in the schedule at all, but was subsequently presented to the most successful local exhibitor as an acknowledgment for the way in which he upheld the character of the district over which the jurisdiction of the society of which he is a member extends.—Aliquis.

I cannot agree with your correspondent "Justice," that secretaries and committeemen should not exhibit poultry at their own shows. Where a committee is composed, as it always should be, of honourable men, they will always appoint honourable judges. Now these gentlemen are introduced to a show room with a competent man, or men, to attend upon them—*i. e.*, to handle birds, when they wish it, skilfully and with care, and to attach the prize cards to the pens bearing the numbers written down by them. The judges should, and I have no doubt do, see that these cards are attached strictly in accordance with their given judgment. Thus managed, the office of a poultry judge is a very simple and straightforward, though often a somewhat difficult, task. There is nothing to indicate from whence came the birds before the judges, or to whom they belong, and they have no right even to guess at these irrelevant questions. Under these circumstances I see no impropriety in committeemen exhibiting, nor ought any unfairness or injustice to arise from the fact of their doing so.

But as regards the system of "local exhibitors being allowed to compete with the same birds for both local and general prizes," I fully concur with "Justice." In fact I would contend, that if the legitimate object of poultry shows is to encourage improvement and friendly emulation in the breeding and rearing of every species of domestic fowl, then "local" prizegiving is highly injudicious, and suicidal to the best intentions of the show. Instead of localising competition I would rather see it become international.

In cases where local prizes are offered to local specimens, I think with "Justice" that the "same birds" should not be allowed to compete for another cup also. It is calculated to induce feelings of distrust and doubt in the minds of absent exhibitors, and is therefore prejudicial to the success of poultry shows.

I venture to send you these few lines because I think the expressed sentiments of poultry-fanciers on these subjects calculated to improve and raise the general tone and management of our exhibitions throughout the kingdom.—Gloucestershire.

Death of Mr. J. J. Fox, of Devizes.—We are sorry to have to record the death of this gentleman, which took place suddenly on Wednesday last, October 27th, at the age of sixty-five. Mr. Fox was a most kindly benevolent man; he was an ardent horticulturist, and a keen poultry and Pigeon fancier. Some years since, he wrote a good deal in this Journal about his favourite fowls—Malays. His finely-chiselled and benevolent face was well known at poultry shows. Mr. Fox was also devoted to the microscope, and a very frequent correspondent of "Science Gossip." Indeed, he seemed to love everything that God had made. Mr. Fox had succeeded in life, and passed his latter years in following his favourite pursuits. In his quiet room looking into his garden, with a microscope in the window, and his loved books around him—among them always

the last week's "Journal"—he presented the picture of a man who knew how to spend his hours of retirement happily. Mr. Fox was a member of the Society of Friends, and was much respected by men of all creeds in Devizes as a good Christian man.—WILTSHIRE RECTOR.

PRIZES FOR FRENCH VARIETIES OF FOWLS.

As a breeder of Crêve-Cœurs, I think they and the French varieties generally (considering their valuable qualities as layers, birds for table, or ornamental poultry), are not placed in a sufficiently honourable position by many gentlemen who undertake the management of poultry exhibitions. In fact, they are frequently left entirely without a class. For instance, I have written for and received the following catalogues of shows selected from your list—Chester, Bradford, Oakham, and Leeds, and find no class for any French variety in any one of them. Now, considering the competition we meet where classes are allotted to us, and the large and increasing number of breeders interested in these fine birds, I think we ought to have more opportunities to learn whether our favourites are as good specimens as those belonging to other exhibitors.—BLACKBIRD.

POULTRY-KEEPING IN AMERICA.

IN poultry management there seem to be some particulars on which light is needed on your side of the water as well as here. For the first time in ten years I have this season been troubled by feather-eating fowls, but find no remedy. I had some experience a few years since with a disease on the legs of fowls, appearing like an eruption, and occasioning a rough warty appearance. I thought it contagious. I let a neighbour have a broody hen thus affected to sit, and the chickens hatched became affected also, nothing of the kind having been seen amongst his fowls before. In January, 1868, I received three Houdans from Messrs. Baily & Son; they were perfectly smooth-legged, and are so still, as were all their chickens of last year (more than fifty), but this year I have noticed three with a slight tendency to feather-leg. One was hatched early in spring.

Afterwards I received a pair of Houdans from Mr. J. C. Cooper, Limerick; all their produce are smooth-legged, but in a brood hatched in August from the Cooper hen by the Baily cock there were two showing feather-legs. Some two or three feather-legged fowls have run with the Baily cock occasionally. Must I believe this to be the cause of his producing these feather-legged chickens? I am told that a slight feathering on the leg is often seen amongst Houdans, even imported ones; is there anything in their original make to cause it, or that they have picked up and incorporated in their constitution so that it crops out occasionally?

In January last I noticed a fine large pullet, a cross between a White Dorking and a Brahma, on her nest apparently dead. She had not laid, and I supposed her death was caused by her efforts to do so. I was very sorry to lose her, as there were four sisters, much alike, all laying. I took her out some ten rods into the woods, poised her on my hand, and tossed her as far as I could; the snow was about a foot deep, and hard on the top, and she came down on it heavily, and lay as she struck, feet upwards. My thought on hearing her strike was, if there is an egg there it is surely broken. About ten days afterwards I saw one of these crossbred pullets on a nest, and when I came away left the door open, so that the fowls might come out. After a time I noticed the three pullets outside, and went for the egg as the weather was rather chilly, and was astonished to find the first-named bird on the nest, alive, well, and laying. This brought to mind directly the big egg I had found about the time of the supposed death of this pullet. I do not remember the dimensions, but it measured somewhere about 8½ inches round one way; it was in the last-named nest, and it seems probable laid by this pullet after her snow bath. Was not this the best treatment, aside from the roughness, that could have been adopted? She was rather shy for a long time, but is all right, and has laid many a large egg since.—PEGAN, *Wellesley, Massachusets, U.S.A.*

[We are more than pleased with the communication of our transatlantic reader, and wish heartily there were a more frequent interchange. We have advocated it for many years, and shall be indeed glad if this letter should prove the harbinger of a continued correspondence. If we can name no cure for the plague you speak of, we can say whether we suffer from the same; if we do, we can state all the symptoms.

We have also suffered from feather-eaters for the second time this year. We have large pens opening on an orchard. We have Buff Cochins, Grouse Cochins, Houdans, Spanish, Crêve-Cœurs, and Brahmas. All are fed alike, and nothing is neglected that is supposed to be good for their health. First Houdans took to feather-eating; then Spanish. They did not do it by halves, they positively ate part of the fowls; with the exception of the principal feathers of the tail and wings, none remained. The birds were in perfect condition, and fat; the hens laid. The first experiment was to reduce the food as much as might be consistent with health; they were also supplied with lettuces, and spots of earth were turned up daily that they might search the mould—useless. Next, the fowls were rubbed all over with the bitterest ointment a chemist could make. The fowls bit at it, shook their heads, seemed as though they would try to spit it out. Then they went up to a bird where a bare and almost raw spot peeped temptingly through the ointment, looked at it, and withdrew, and came again, and at last, plucking up courage, went boldly at the tempting morsel. This was a failure. Next we put them in confinement, two or three in a small cage; they did not eat the feathers so much as when at liberty, but they still ate them.

The Spanish carried on the filthy practice worse than the Houdans. In neither case, with the exception of the tail feathers, did they pick the flesh. It was the feather only they wanted, and as fast as stubs appeared for forming the new feather, they picked them out.

The disposition of the pens where the propensity manifested itself was as follows:—In one pen were Buff Cochins; next, Light Brahmas; next, Grouse Cochins; next, Houdans; next, Spanish; then Crêve-Cœur. The two middle pens, Houdans and the Spanish, were desperate feather-eaters. They seem to delight in it most in very hot weather, and are, we think, disposed to renounce their evil ways now winter is drawing nigh. They never had the habit till last year, and we are without a remedy for it.

We have not told any of the hundred and one experiments we have tried in the way of withholding or changing food; we have not mentioned the numberless nostrums and certain cures recommended to us. We consulted our medical man, and succeeded in making him take an interest in the case. We even condescended to ask the old women. They said, "They knowed nutthin about it. Their chickens never did nutthin of the kind." No one could help us, no one did help us. We have heard of it from all quarters. The most experienced say it is a new thing, and they have no remedy for it. We have noticed all our lives that about the moulting time, and in certain condition of body, the moment a feather falls from a hen, another picks it up and swallows it. We have known one become a feather-eater, but she was always detected, and removed. We have never known anything like this year's experience. We have never known the cock become a convert to the filthy habit.

The warty appearance of the legs is common in old Cochins. It is seen sometimes in chickens, but seldom. In the latter it is to be cured with compound sulphur ointment; in the old birds we think it incurable. We have never seen it in any breed but the Cochin and the La Flèche. A Cochin is old and worn out at three years, and it is at that age this sort of "gallinaceous elephantiasis" appears.

We can say nothing to the appearance of feathers the second year on the legs of the Houdan. It is a very common occurrence to find a tendency to feathered legs in many breeds. It is very common in the Dorking. We are not prepared to say whether the feathered-legged hens caused others to have feathered-legged chickens, but there are strange things of this sort. We can vouch for the truth of the following:—A person well known to us had a yard of Spanish fowls at a very lonely spot far from any house. There was no other breed, with the exception of one hen, a Chittagong, kept for her valuable properties as a mother. She had a reddish-brown plumage. After a time many of the Spanish came with a brown, others with a red saddle. Our friend, vexed with such a result, consulted those whom he thought calculated to give him a good opinion. One, a person of much experience, but living very many miles from the place where the fowls were kept, at once asked the question, "Have you a hen of any other colour running with them?" Our friend said, "Yes." "Well," said he, "remove her, and you will remove the evil." It was so. There are curious facts to be noted in poultry, and if they can be explained, so much the better. We have at the present time a Spanish hen which

has moulted nearly white, one of twenty, all the rest blac k We know this is common, but we cannot explain it.

We are not prepared to say your treatment of the hen was the right one; nor do we believe in a recurrence of the same good fortune if you repeated the treatment. In our opinion a feather dipped in oil, and introduced till the passage was entirely lubricated, would be quite as effectual, and less dangerous. We once threw away a Spanish hen for dead. She was thrown on a dunghill, and partly covered. She was alive and better the next morning, lived to make one of a cup pen, and was sold for £10.]

AUCTION AT THE BIRMINGHAM POULTRY EXHIBITION.

I BEG to indorse all that Mr. Henry Leach says with regard to the day fixed for the sale by auction of birds at Bingley Hall. Monday is a most inconvenient, not to say impolitic, day for the sale. Many cannot, and I am thankful to say if they could will not, travel on Sunday, and consequently are entirely prevented from being present at the sale; and if they do manage to arrive in Birmingham by eleven or twelve o'clock, what time and opportunity are afforded them of looking over the birds? None whatever; and no one really caring for good poultry will "buy a pig in a poke" in this manner. No. Let the Council fix on Tuesday as their day of sale; then every one will have the Monday for the inspection of the birds, all will be able to attend the sale in person or by proxy, the competition must necessarily be greater, and funds accrue to the Society. Should answer be made that many are in Birmingham on the Monday who do not remain till Tuesday, and therefore would not be at the sale on the latter day, I would say, Let them entrust their commissions to the obliging auctioneer, who will faithfully execute them.—A. K. C.

PERMIT me to endorse the opinion expressed by Mr. H. P. Leach, that the time and day fixed by the Birmingham Poultry Show Committee for the sale of birds are most inconvenient to persons anxious to attend, and living some miles from that town. Many, I think, like myself and Mr. Leach, may not wish to be in Birmingham on the Saturday, or to be compelled to travel there by rail on the Sunday. Thus, there must be persons who will be prevented from attending this sale by these circumstances only, who would otherwise be present at it. This appears to me a positive injury to the sale, and the owners of birds, as well as a source of disappointment to likely purchasers.

If others think with Mr. Leach and myself, I hope they will express their opinion in your columns, and thereby endeavour to obtain one day's postponement of the sale by the Birmingham Committee.—GLOUCESTERSHIRE.

THERE can be no doubt that the proposed alteration of time for holding the poultry sale at Bingley Hall would be hailed with great satisfaction by a large number of exhibitors residing, like myself, at a distance, and who cannot under the present arrangements be present at that sale. There are many whose commercial engagements prevent their leaving home on the Saturday, and who would conscientiously object to travelling on Sunday; and even where these obstacles do not exist, there are the expense and the inconvenience of being in lodgings up to the morning, which quite preclude their attendance at the sale. As for those who, like myself, have official duties to fulfil on the Sunday, it is quite useless to entertain a wish to attend the sale, as there is no possibility of reaching Birmingham on the Monday till the afternoon. Let the sale take place, say at 4 o'clock on the Monday afternoon, or on the Tuesday morning, and it would afford all who are now unavoidably excluded, a fair opportunity of being present.—J. ELLIS, *Bracknell, Berks.*

SPURIOUS HONEY—STRAW VERSUS WOODEN HIVES.

I THINK all agree that the practice of feeding bees with sugar for the purpose of filling supers, and afterwards selling or exhibiting them as supers of honey, is dishonest, and should be discouraged. That Mr. Pettigrew should have mentioned the class of hive, from which the supers he detected as filled only with sugar and water had been taken, is very unfortunate, as I quite agree with "A LANARKSHIRE BEE-KEEPER" "that it is much better to let sleeping dogs lie," especially when their bark is so discordant; but that Mr. Pettigrew cannot detect sugar from honey after tasting it, is ridiculous. I may remark that he this year took to the heather upwards of fifty hives, and that, I believe, he secures on an average about 500 lbs. of honey annually, and this is done without intentionally killing a bee. He has this year filled five glass supers weighing 13 lbs. each, and one straw super weighing 22 lbs. On returning from the moors I assisted him to weigh three hives; one a swarm of 1868, weighed 70 lbs.; the first swarm from it this year weighed 80 lbs., and the second swarm 40 lbs., making 190 lbs. from one hive this season; this, of course, is exceptionally good for this locality. I myself am an enthusiast in bees, and living near Mr. Pettigrew, these facts came to my knowledge, and I merely mention them that those of your readers who are not fortunate in knowing Mr. Pettigrew, may be assured that he is no "novice passing his opinion on honey."

Respecting the Stewarton hives, they are, probably, as good as any other made of wood. I commenced with five made on Mr. Tegetmeier's plan, and I do not think there are any better; but I soon found that the fault lay not in the construction of the hive, but in the material it was made of. I found that in cold weather the wood on the inside of the hive was covered with condensed moisture; the bar frames, to a great extent, kept the combs from contact with it, still the stagnant moisture caused them to mould and discolour. I afterwards adopted a remedy which your readers using wooden hives would do well to follow; I obtained some boiler felt—a very excellent non-conductor of heat, and covered the outside of the hive with it; any other non-conductor which will prevent the hive from being influenced by the temperature of the outside atmosphere, will do. This covering is as essential to keep out the heat in summer as the cold in winter.

Now, we Manchester men prefer the article which gives the largest and best result with the least outlay of cost and trouble, and I found that with good straw hives I could do almost everything which could be done with the most elaborate, and that the bees did much better in them than in the unprotected wood. Now, these straw hives cost me about 3*s.* each; they are 16 inches wide and 12 inches deep, and are patterns of good workmanship. I have them made with a crown of wood 6 inches in diameter, worked in the straw, with a 3-inch hole bored in the centre of it. This is fitted with a plug or bung, and on this top I can set a super made of glass, straw, or wood, taking care if it is of glass or wood, to wrap it carefully round with woollen material.

I do not think any of your readers will be led away with the "LANARKSHIRE BEE-KEEPER'S" assertion, that "doubtless the shape and material have very much to do with the quality of honey collected," and they will find that whether the super is of glass, wood, or straw, the honey stored in it will be precisely the same; but as regards quantity, the bees prefer the straw, next the wood, and last of all the glass, though the appearance of the glass is prettiest.

I also do not agree with "LANARKSHIRE BEE-KEEPER'S" assertion that "a good judge of honey knows honey and comb without tasting it." The honey is collected from so many kinds of flowers, the colour and consistency varying in each case, that it is impossible to tell by the eye alone. Also, unlike his, my experience shows me that even in the height of the honey harvest, my bees will take either syrup made of sugar and water, or honey, if placed where they can get to it, in preference to collecting it from the flowers in the fields; indeed, I always assist my new swarms by giving them a couple of pounds of lump sugar dissolved in a pint of water. By this means they make comb faster than if compelled to seek their food, thus providing the queen with cells in which to deposit her eggs, which would otherwise be lost, and getting out a lot of brood earlier than they otherwise would do.

In conclusion, the stronger the stock, the more workers there are, the more honey there will be collected; consequently do not use small hives: and the material best adapted to resist changes of temperature is the best to make them of; this, in my opinion, is straw. I place a small cushion filled with hay on the top to cover the wooden crown, and thatch the whole neatly with straw, thus keeping off the wet, and giving my apiary a neat appearance.—A MANCHESTER MAN.

CONFLICTING OPINIONS ON BEE-KEEPING.

I AM anxious to begin bee-keeping, but am greatly puzzled by the conflicting advice given in books. In the *Times* "Bee-keeper," the author says, that bee-houses are a positive necessity, no matter how ill-constructed they are so long as you have them.

Now in "Bee-keeping for the Many," page 5, and in many other places, it is said that on no account are you to put hives into bee-houses, but to keep them out on a stand with a milk pan over them to throw off the wet. Will you kindly give me the benefit of your experience on this point, and let me have an answer in your next number? Also, as to bee hives; the *Times* "Bee-keeper" highly recommends the Ayrshire box hive, which consists of several boxes, but says they warp if exposed to the sun and rain. Do you think I could keep them without a house? An answer to these questions will greatly oblige your subscriber.—APIS.

[Dr. Cumming, the so-called "*Times* Bee-master," is no authority on the subject of bees, and it is therefore by no means surprising to find him wrong in his statements. So far from bee-houses being a positive necessity, their disadvantages are considered by many to outweigh their advantages. If hives with fixed combs are alone used, a closed bee-house will effectually shelter them from the weather, and from extreme cold in winter, but care should be taken to make the entrances as dissimilar in appearance, and place them as far apart as possible, or great loss of life will occur in the spring from workers mistaking their hives, and more serious consequences may follow similar mistakes on the part of young queens returning from their wedding flights in summer. Where the moveable comb system is in use, however, almost the only possible, certainly the only convenient, bee-house is, either a verandah or a lean-to shed erected against a wall with sufficient room to operate behind the hives, and closed at the ends, but open in front, or covered only with pheasant wire, in which must be left good-sized semi-circular orifices in front of each hive. We ourselves have no bee-house, but cover each hive with a light wooden outer case and roof such as delineated in page 18 of the last edition of "Bee-keeping for the Many." The Stewarton hive is a good one, but requires the protection either of a bee-house or an outside case.]

OUR LETTER BOX.

FOWLS DYING (*W. L.*).—The feeding of your fowls is good enough for any poultry, and a yard full of stable dung has always been held to be the great desideratum for the health and well-doing of fowls. Where a number of previously healthy birds are taken with the same symptoms, and die of the disease of which these are the evidence, we look about for the cause. Are boot-tops cleaned there? and is the water thrown out where the fowls can get at it? This may be the cause, if they drink it. Are their crops full and hard when they are taken? If so, they are crop-bound, or there is a stoppage somewhere. It is from something that is picked up and eaten, or something that is drunk. If there were any general cause, its effects would be general, and all the birds would suffer; but here it is evidently something that is picked up, and that kills. There is, in our opinion, no fault in the health of the fowls, and we doubt not close observation will enable you to discover the cause of the mortality. The treatment we advise you to adopt, is to purge them thoroughly as soon as they are taken ill, and then to administer stimulants. Unless we are mistaken, their evacuations are green and slimy.

WHITE BASE OF TAIL FEATHERS OF PARTRIDGE COCHIN COCKEREL (*Fred*).—It is not desirable, but it is hardly a disadvantage.

TAIL FEATHERS NOT ESCAPING FROM THEIR CASE (*New Beginner*).—Moisten the part where the faulty feathers grow with plain ointment; spermaceti will do. A heated condition of body often hinders the proper formation of the principal feathers. That can be remedied by opening medicine, or by change of food. Lettuce is excellent feeding for fowls when moulting; meat, peas, and hempseed are very bad. Sometimes the feathers cannot pierce the skin, and then they grow under it, looking like a worm crawling about. Such never becomes a healthy feather, but it may be assisted if a stout needle be put under it, and brought through the skin. As a rule, the formation of faulty or diseased feathers is a bad sign.

INDIAN CORN FOR FOWLS (*A. L.*).—Our experience of feeding on maize has not been confined to poultry. We have also fed pigs on it. When we attempted to feed on Indian meal, none of our animals would eat it. They would pick up the whole corn ravenously, but they would not touch the meal. The Irish Turkeys are fed on potatoes. They are exceedingly fat, but they have no flesh, and their livers are immense, both in size and fatness. We fed some Geese for table purposes on Indian corn. In appearance they were beautiful, but they proved very imposters when put before the fire; all the fat disappeared, and the lean assumed and retained the colour, appearance, and toughness of indiarubber. It is a good help, but it is bad if it is the sole food. We prefer ground oats to barley, and think when the mixture is given it should be in the proportion of one-third of Indian meal to two-thirds of ground oats. We believe that it is the most economical feeding to give the best of everything, and we have more faith in oats and barley than in maize and potatoes. Maize is much liked by poultry when whole, and is very useful in severe weather, because the small birds cannot swallow it.

FOWLS AND THE FOOT-AND-MOUTH DISEASE (*C. E. I.*).—We have heard of no case where the foot-and-mouth disease of cattle has been communicated to any biped. We cannot think the chickens can have caught it, and in such case we must seek the cause among ordinary things. With the changeable weather we have now, many things are injurious that would be innocuous in settled summer weather. Damp and cold reign now in places that are frequented and sought in hot weather for the sake of their coolness. Do the fowls roost properly? Are they protected from draughts? Is the flooring of their house of earth? Middlings may be good food in summer, but you may leave it off now. Give oat and barleymeal slaked, and if, when the weather changes for bitter east wind, you give a little strong beer, it will do no harm. We do not compass your meaning when you say "they have no crop." If you will make that a little clearer, it may help us to advise you more fully. In all such cases as you describe we use stimulants, beer and even wine, freely. They keep the bird up, and enable it to live through the crisis of the disorder. We also administer pills of camphor with marked benefit.

TURKEYS WITH SWOLLEN HEADS (*W. T.*).—In all probability your Turkeys when young were left to the tender mercies of their mother, and she had her liberty. Whenever this is the case, the brood suffers. The hen should be confined till the young are old enough to shift for themselves. The hen has no idea of measuring strength, and will drag her poor brood about till they have perished. The survivors have swollen heads and knees; they do not thrive, and are just as you describe yours to be. Keep them very dry, especially let them have a dry roosting place, give them plenty of bread and ale, let them have every night for four nights two pills of camphor, each as large as a horse bean, and let them have camphor in all their water. This will cure it; it would have done so more easily had it been adopted at an earlier stage of the disorder.

DESTROYING EGGS' VITALITY (*Housewife*).—Many means are tried; we take our chance. Some take a fine needle and pass it through the egg from end to end, others shake each egg vigorously. We believe there is no certain mode of destruction, unless you spoil the egg for breakfast purposes.

FATTENING DORKINGS (*Idem*).—You may have fowls in good condition fed and treated as yours are; but if you want them to be fat, they should be shut up and fed with ground oats slaked with new milk. Give no rice nor whole oats. Buy Baily's book on fowls. It describes the whole process.

TWO NAILS ON ONE TOE (*B.*).—It would be hard if the pullet lost, but it must be considered a disadvantage. If it be only an extra nail it would very likely escape notice.

EXHIBITING DARK BRAHMAS (*H. B.*).—Your fowls are good enough for the selling class. The first described is small, but the description is that of a good bird. You state this bird has no vulture hock. Are we to infer from that, that the heavier bird has? If he has, that in our mind would at once settle the question. The vulture hock would weigh more against him than the extra pound and a half in his favour. Supposing the larger bird has no vulture hock, we should exhibit him in preference. You have been rightly informed about the wing; a perfect wing should be as you describe, and it should have no brown. The defect in your bird is trifling. It is with fowls, as with other things, much easier to describe perfection than to find it.—B.

BOOK ABOUT BEES (*Sultan*).—"Bee-keeping for the Many," published at this office, price 4*d*. The simplest hive for taking honey is Payne's Improved Cottage Hive made rather larger than therein described, say 16 inches in diameter, by 8 or 9 inches deep.

MINORCA OR ANDALUSIAN FOWLS.—"H. F." wishes to know where he can obtain some cheaply.

MATCHING DIFFERENT PIGEONS, &c. (*H. Ekeley*).—A yellow cock and black Barb hen would probably breed a yellow and black in each nest, but if there were black blood in the yellow, more blacks, and *vice versâ*. A crested Barb and a smooth head would probably breed point heads, and so spoil both, or, it might be, one smooth and one crested. A yellow Jacobin cock and blue hen would produce a very bad colour. We are afraid a cock Pigeon infertile with one hen would be so with any other. Of course, you are sure the defect is in him. We tried a very valuable cock Jacobin with several hens, but in vain.

CANKER IN PIGEONS (*W. N. H.*).—Apply a strong solution of alum with a feather twice a-day. If the swelling become loose, remove it, and again apply the alum and water. Feed your bird very sparingly, and pull out some of the feathers of the tail.

GERMAN BEE JOURNAL (*C. F. B.*).—You can have it through Messrs. Trubner & Co., Booksellers, 60, Paternoster Row, London.

PARSNIPS FOR COWS (*B. B.*).—Take some up and store in sand, to use when the ground is hard frozen; but the major portion may be left in the ground, and taken up as required. They are not injured by frost.

SATINETTE PIGEONS.—Mr. A. H. Stewart has enclosed to me a letter from Mr. Noyé in which it is stated that Mr. Stewart bought of him the Satinettes which gained the first prize at Bingley Hall in 1868. He sold Mr. Yardley another pair which he, Mr. Noyé, thought were the best.

GOLD AND SILVER FISH (*Rus*).—We do not think that they would live in rain water discoloured with soot. Charcoal put in would have no influence for their well-doing.

ZEBRA WAXWINGS (*A Subscriber, H. T.*).—We do not know of any instance of the Zebra Waxwing birds breeding in confinement. We should, however, treat them the same as we do Canaries, by putting a pair in a spacious cage, and giving them boxes to form their nests in. Their food should be chopped egg boiled hard, bruised hempseed, mawseed, and crumbs of bread.

ELDER WINE NOT FERMENTING (*C. G.*).—Violent fermentation is not needed. If left open in the cask for about a month and then bunged down, the quiet gentle fermentation renders it vinous. If, however, you wish for a strong visible fermentation put into the wine a toast rubbed over with yeast.

POULTRY MARKET.—NOVEMBER 3.

THE quantity of poultry has increased, and we have a dull trade. November is generally "the winter of our discontent," and it opens as though the present would be no exception.

From observations taken near London during the last forty-two years, the average day temperature of the week is 49.3°; and its night temperature 34.1°. The greatest heat was 63°, on the 12th, 1841; and the lowest cold 18°, on the 15th, 1848. The greatest fall of rain was 1.24 inch.

THE GREAT ADVANTAGES AND SMALL DIFFICULTIES OF SMALL GARDENING.

KNOWING how gladly I always receive any information through your Journal on the cultivation of my garden, I am led to believe that many of your readers will accept a few remarks from a cottage gardener on the minor points of cultivation.

My own greatest difficulty has arisen not so much from not knowing how to grow anything as in making a choice of what is really worth growing, from the great diversity of kinds to be found in seed lists; and whilst agitation is going on about the alteration of the land laws, in my opinion every householder who desires it ought to have the option of possessing a garden, to give him some chance of healthy recreation, and to counteract the evil influences of the tap-room.

In a few words I will state how I overcame the difficulty of securing gardens to the working classes in my native village—Chester-le-Street. After looking out for a long time I obtained a five-years lease of a fine old pasture field four acres in extent. It had not been broken up for a very long time; but the prejudice against the breaking up of old pastures was overcome by stating the fact, that if at any time it were found desirable to again lay it down in grass, in consequence of the high cultivation of cottagers it would be greatly enriched, and correspondingly enhanced in value. Immediately on coming into possession last November, I divided it into patches of 22½ yards square, and readily found twenty-four tenants at £1 each, and in some instances two joined to take one garden. A large space was left in the centre of the field for a recreation ground at all times open free to the public. The result has been not only the satisfaction of benefiting the place, but a profit of about £7 a-year. My reason for giving the above instance is to encourage others with more means, to bring their influence to bear on so desirable an object as securing a piece of ground (sinking both the profit and pleasure to be derived by its cultivation), where the mechanic, after attending in a confined atmosphere to, in many instances, an unhealthy employment, can resort with his family at pleasure, and obtain all the blessings of that great disease-destroyer — the bracing, fresh air. As regards the first year's produce, with a few exceptions, to which I shall probably refer, it has exceeded our most sanguine expectations.

In naming a few flowers worth growing and stating my experience in growing them, let it be understood that I am not a professional gardener, but only give the experience of an amateur. I shall commence with my favourite the Gladiolus, and describe as plainly as possible the cultivation of six dozen bulbs in a bed in one of the new gardens. Having plenty of soil and turf, I raised the site of my bed about 15 inches above the general level, thus obtaining a depth of about 2 feet of soil with good drainage. I then collected all the old wood I could lay hands on, placed it upright, levelled it with a quantity of turf, and burnt the whole, thus securing a good supply of charcoal and ashes. I spread the latter, about 3 inches thick, over the bed, and gave a good dressing of rotten hops I am of opinion that rotten hops form one of the very best of manures for the Gladiolus. I then turned over the whole several times. I next potted the bulbs in 4-inch pots, surrounding them entirely with charcoal, and placed them in a Cucumber frame, giving water very sparingly until they had pushed well through, when I removed them to a cold frame. I planted out when the plants were about 6 inches high, giving to each another handful of charcoal. The result of this mode of cultivation was my obtaining the first prize in the open class for seven varieties at our exhibition on the 17th of August, there being three competitors, and the third prize for three varieties in the cottagers' class, in which there were five competitors, failing in this instance solely through my blooms not being sufficiently expanded, as in quality they far exceeded the others. Subsequently I obtained five prizes at other exhibitions, all in the open class.

The Gladiolus, if good drainage be secured, likes plenty of water, but on no account use it fresh from any spring or deep well. You must secure what no garden ought to be without—a good-sized tub, the wider the better, that the sun may have the more surface to act upon, and two or three smaller ones for guano, soot, or any droppings one can collect. Should the spikes at any time show a yellow tinge, give a good drenching of soot and water, which will generally have an improving effect. The grower must not lose heart if they occasionally go wrong notwithstanding all his care and ingenuity. I will give an instance: I had a fine bulb of Stuart Low which threw up five spikes of a sickly yellow; when 4 or 5 inches high I washed and examined the bulb very minutely, and found that whilst the others were filling the pots with roots, in this instance they were not more than an inch long. After washing, I could not detect the slightest trace of any disease or grub; I carefully repotted it, and planted it out with the rest, but the spikes never grew more than a foot high, retaining the same sickly hue until they all died down. On taking it up I found that the roots were entirely decayed, and that it had formed two bulbs of about the size of a horse bean, the old bulb still remaining comparatively fresh. With two or three exceptions the rest have all done well, and produced a fine collection of bulbs.

I shall now give an opinion of the kinds I think the cottager ought to secure in making his first purchase, especially if intended for exhibition, and as the sum of 5*s.* is as much as can, on an average, be reasonably expected to be invested, I will try to lay it out to the best advantage. If you buy three bulbs for the money the chances are a hundred to one that you will not have three spikes on the day you want them; and selections at 4*s.* or 5*s.* per dozen for exhibition purposes will probably be just so much money thrown away. I recommend the purchase of four Brenchleyensis, the price being low, and to make almost sure of having one spike in a fit state for exhibition on the day of the show. Occasionally, even where good collections

are grown, exhibitors have recourse to this variety early in the season. Buy two bulbs of Penelope, there is seldom a stand without it; one Ophir, one Vesta, one Comte do Morny, and one Velleda, which is one of the very best kinds for opening quickly in hot weather—a great advantage. Where the stock is small you will thus procure for your money ten bulbs that, with good management and ordinary good fortune, will produce spikes all fit for exhibition. Your first year's experience, and putting down the names of any varieties that take your fancy, choosing those as round in the petal as possible, will enable you to hold your own in future. The six sorts that I have chosen to add to my collection next season are Adolphe Brongniart, Princess Mary of Cambridge, Milton, Thomas Mathven, Piccioli, and Madame Furtado.

I intended next to have said a few words on Dahlias, of which I have grown about three dozen varieties, but I shall feel greatly indebted if some one more qualified would give a little plain advice on their management, and name a few sorts suitable for cottagers. We want free bloomers, and kinds which are easily got up, as a cottager cannot be expected to grow more than one of a sort. One that has especially taken my fancy is Purple Gem, a good bloomer; and every bloom, though rather small, has been fit for exhibition.

I intended to have made a few remarks about nurserymen and their assistants at exhibitions, and possibly I may do so at some other time. I think nurserymen will agree that it is not by prizes, but by the sale of their plants, that they live; and how can they expect to sell their plants if they continue to allow their assistants to exhibit in the amateur class at many of our flower shows? What chance has an amateur or cottager with his dozen plants against the nurserymen with their thousands? The result will be that the amateur who loves to exhibit will lose heart, and cease to grow flowers.

Asters like good rich soil; do not be too late in sowing; sow in a cold frame to prevent their spindling up. I know nothing so good for exhibition as Truffaut's and the Dwarf Chrysanthemum-flowered.

Stocks are especial favourites of mine; apart from their beauty, in the dusk of the evening what is half so sweet? Do not be in a great hurry to sow, as it is a pity to see them going off when everything else looks gay. I like the dwarf and large-flowering German the best. Much has been said about their damping off. I fear we occasionally go to the other extreme, and dry them off. Sow in boxes in a cold frame, and be sure that the boxes are placed level, in order that moisture may not tend to one side. Give gentle waterings from the rain-water tub, do not be too late in pricking-out the plants into other boxes, and on no account let them become drawn up, but rather let them grow like little pyramids as broad as they are long. What is worse, on passing along the border of a garden, than seeing Stocks some 8 inches long flat on the ground, or just turning up an inch of their heads, as if ashamed to be seen in such a pitiable predicament? I will describe a bed of Stocks I had this season containing 416 plants, the colours being kept separate. I planted eight rows by six of scarlet in the centre, and then arranged rows of different shades all round, with dwarfs at the outside. I never tired of looking at them, and I felt it was quite a compliment to be told by both ladies and gentlemen who employ gardeners that it was the finest bed of Stocks they had ever seen, the plants so shrubby, and not one failure.

Another favourite of mine is the Verbena, of which I have grown about twenty-six varieties this season. It likes rich peaty soil, and in a few words the secret of success is to keep the plants growing, never allowing them to become infested with the green fly, or to be stunted. This season in cleaning them I have used nothing but water with a little soft soap, after taking the chill off a little, placing those in pots on the sides of the pots, and giving them a good syringing as much underneath as possible. Should the plants become affected with mildew, give them a slight dusting with sulphur. For pot culture choose shrubby growers. Cannell's Beauty of Kent is a very desirable kind for this purpose. For cut blooms, the best I have grown, and those I can recommend, are Géant des Batailles, Warrior, Reine des Roses, King of Verbenas, James Birbeck, and Miss Wimsett. Not having the means of wintering Verbenas satisfactorily, I generally obtain by post a new supply at a very small rate, from a nursery, my transactions with which have been so thoroughly satisfactory that I feel tempted to give the address, did you not justly refrain from giving the preference to any particular firm. It cannot, however, be too widely known, that with our cheap postal and railway communication, it is in the power of anyone to stock his garden with the most choice plants from nurseries three or four hundred miles off, at a singularly low cost, though, of course, if one can be supplied as well from nurseries at home, by all means I would give them the preference.

The Pansy is another old flower that never seems to go out of fashion, though I confess it has such a host of enemies that I have nearly promised to let it grow at the outside of my garden in future. The wireworm seems never so happy as when snugly ensconsed in the heart of your favourite Pansy. A troublesome little insect, which I think is the red spider, is quite a pest. Snails and caterpillars have an especial fancy for Pansies. The plant requires plenty of river sand, made rich with sheep droppings. Let your bed be so situated, that it will be exposed to the morning sun, and cover it entirely with charcoal, or one half burnt sawdust. Pansies like this, and slugs do not. In dry weather damp them as often as you like. The only means that I can find of destroying the red spider is, if the blooms are eaten, to pay them a visit at night with a candle, and most likely the depredators will be secured. In judging the quality of a Pansy—say a yellow ground, you must have the eye as small and distinct as possible, the blotch, too, as distinct as possible; the ground or yellow portion all of one shade, with the centre petals touching each other at the top; and the belt as distinct and regular as possible. Having obtained these qualities you must grow your blooms as large as a crown-piece, and they will be fit for exhibition. In a stand of six, I like to see a good black, a yellow, a white, a yellow ground, a straw-coloured ground, and a white ground.

I will reserve a few words on vegetables for a future time.—Joseph Witherspoon, *Chester-le-Street.*

MARINE AQUARIA.

Many of the lady readers of "our Journal" no doubt annually visit the seaside, and while there, in addition to gathering up health and spirits, will also find intelligent amusement in collecting specimens of seaweeds. Those who happen to be botanically inclined will mount and classify them scientifically, while those whose proclivities are merely artistic will put them together in picturesque groups, quite wonderful in their way, and carry them off as souvenirs of sea breezes, pleasant days, and sundry happy incidents. But the delicate forms of the finer Algæ, to be duly appreciated, must be seen in their native element, and a little bit of the great ocean imprisoned in a handsome glass case forms a most interesting object either in the drawing-room or conservatory. Salt-water aquaria are by no means rare in first-class gardens throughout the country, but they are mostly of the large expensive sort, and are devoted principally to the keeping of marine animals. Of these curious creations, with their mysterious forms and habits, it is not my intention to say much, but there is a strange fascination about them, and those who have not made themselves a little familiar with them will find on doing so that they had hitherto left uncut one most interesting page of the great book of nature; only a few of them must be kept, even when seaweeds are the first consideration, the presence of each in the aquarium being essential to the health of both.

The tanks themselves can be had of many forms and sizes, and constructed of various materials, the bottoms being stone, terra-cotta, slate, wood, iron, or zinc. The last two are, however, objectionable. The most convenient and symmetrical form is, I think, an oblong, twice as long as it is wide and deep. For those of small size, such as 18 inches by 9 inches and under, common 21-oz. glass will do; if above that size heavier plate must be used. I have seen some very neat conservatory tanks made with only the two sides of glass, the ends as well as the bottom being of inch slate; they are thus much easier of construction, and therefore cheaper, as well as cooler and less apt to leak, than those with four sides of glass, though perhaps not quite so ornamental.

Having the tank, where to place it becomes the question. The body of water it contains being comparatively small, it must not be exposed to the full glare of the sun, neither should it be continually under a cloud. The north or east end of a greenhouse or conservatory, where it can have a few hours' morning or afternoon sun daily, and where there is a free circulation of air, will do very well in summer; at other seasons it should have the lightest place in the house. The aquaria also do admirably before a drawing-room, hall, or staircase window if it can be frequently open, but dust must be guarded against.

Before filling the tank some miniature rockwork will have to

be contrived, and in doing this a certain degree of caution is necessary. To preserve the plants in health, and keep the water clear as crystal, perfect cleanliness is required, therefore the fewer hiding-places that are made for dirt the better. Any little caverns which are made should be so placed that their innermost recesses can be easily reached by a pair of long, slender, wooden forceps, and all decaying pieces of fronds removed. A little very fine gravel, free from sand, should be scattered over the bottom, and for the other materials fancy or convenience will decide what to use. Brain coral, honeycombed rock, felspar, or pieces of various-coloured marble and granite, all look well. On and among these, in such positions as best suit their different sizes and colours, the Algæ must be anchored. dropping the little bits of rock on which they are growing, or, rather, to which they are attached, into the crevices, or otherwise fixing them, while the exquisitely delicate fronds float freely and gracefully above, like nothing but themselves.

With ordinary care the water may be kept good for a twelvemonth without changing it; under good management it will last for years. To guard against its original density being increased through evaporation, the height of the water when the tank is first filled should be marked upon the glass with a diamond, and whenever it falls below this fill it up to the mark again with fresh rain water; but should any loss occur by leakage, as is sometimes the case, it must be made good with salt water, and not fresh.

In making a selection of Algæ the question of which to grow, owing to the wealth of species to choose from, will rather resolve itself into the negative form, and what not to grow become the puzzle. In a rough way seaweeds are divided into three great classes—the Olive, the Red, and the Green. The Red contains the most suitable for the aquarium. Some of the finest will be found in the species Callithamnion, Bonnemaisoniana, Plocanium, Delesseria, Nitophyllum. The common Irish Moss, Chondrus crispus, and Rhodomenia palmata, the "caller dulse" of the Edinburgh fishwives, are both easily kept and look well. Of the Green sorts the most handsome is Ulva latissima, with long frilled fronds very much resembling those of the Fern Scolopendrium crispum.

I mentioned the water being kept pure and wholesome for months and sometimes years without changing; but I have also known it more than once become foul in a very short time after being first put in, and that, too, without any very apparent cause. If all the materials have been perfectly clean when put in, the Algæ free from decaying matter, and the water procured pure from the sea, not near the mouth of a river, then the opacity, if only of a light milky colour, will most likely disappear of itself after the water has been aërated a few times with a small syringe; but if, on the contrary, the water assume a brandy tinge, however slight, it may be emptied out at once as hopelessly contaminated. When all is well a gentle disturbance with the syringe must be given once a-day. To preserve the chemical balance and keep up some motion in the water, a few of the common little rock fishes should be introduced. Those known as blennies are very lively, and are easily procured and kept; also a few molluscs, and some of the very small crabs, particularly the hermit or tenant crab, whose restless habit of clattering about continually with his borrowed house on his back is most amusing. Last but not least, there are the sea anemones, and some conspicuous spots should be kept on which to place a few of them. An aquarium, even though it contained nothing else but a collection of these, would be most interesting. Their colours are so various—striped, flamed, and jewelled, purple, violet, red, pink, and nearly white, and their resemblance to flowers—living, eating, and, for aught that we know, in some degree thinking creatures though they be—is so striking, that they almost come within the legitimate province of the floriculturist. How they live is a miracle, for I have kept specimens of them seemingly in perfect health for more than eighteen months, and only fed them with morsels of oyster at intervals of five or six weeks. They, as well as all seaweeds intended for the aquarium, should be removed from the rocks by chipping away with a chisel the small piece to which they adhere—no easy task sometimes in the case of the anemones, as they generally affix themselves to some hard smooth surface, or in some snug nook, from which it is rather difficult to take them unhurt.—Ayrshire Gardener.

Royal Horticultural Society.—At the meeting to be held on Tuesday, November 16th, the following prizes are offered—viz.:—By W. Wilson Saunders, Esq., 1, Collection of Winter Bedding Plants, to be exhibited in pots or boxes, £2 and £1: By the Society, 2, Four Chrysanthemums, large-flowered, in pots, distinct (open), £1, 15*s*., and 10*s*.; 3, Four Chrysanthemums, Pompons, in pots, distinct (open), £1, 15*s*., and 10*s*.; 4, Twelve Chrysanthemums, cut blooms, distinct (nurserymen), 10*s*., 7*s*., and 5*s*.; 5, Six Chrysanthemums, cut blooms, distinct (amateurs), 10*s*., 7*s*., and 5*s*.; 6, Twelve Plants bearing decorative fruits, in pots, varied (open), £1 5*s*., £1, and 15*s*.; 7, Six Plants bearing decorative fruits, in pots, varied (open), 15*s*., 10*s*., and 5*s*.

BEDDING PELARGONIUMS—YELLOW CALCEOLARIAS.

Another season is nearly gone, leaving behind it many useful lessons. The effects of the passing season as regards some branches of horticulture have been remarkable, rendering the year one to be remembered and quoted for a long time. Cold, chilling blasts swept over the land, and heavy moisture-laden clouds obscured the bright sky of spring, shutting out the warm rays of the sun so necessary to cherish and develope tender vegetation. Very welcome was the change when the wind, shifting to a more genial quarter, dispersed the dark clouds, and the sun with daily increasing power dispelled the superabundant moisture, penetrating and warming the soil, quickening the motion of the sluggish sap, and animating and beautifying the whole face of nature.

The effects of this protracted cold were very visible in our flower gardens during the early weeks of the summer; even the sturdy zonal Pelargoniums appeared brown and stunted for a time; but at length all worked right, bed after bed put on its best appearance, and the bright glow of the whole design proclaimed it summer.

Although it is intended that these notes should refer more especially to bedding Pelargoniums, yet I must remark, in passing, the great beauty of the beds of Calceolarias this year. I never remember seeing this flower more effective and useful, for the beds of it were in full beauty long before the earliest beds of Pelargoniums. Nothing is so effective in a design as a few bright masses of Aurea floribunda if not overdone; it relieves, it brightens, it beautifies. It is one of those flowers for which we have no substitute; but as with many other bedding plants, its bold and striking colour renders it a somewhat difficult, or rather dangerous subject, for if too much of it be used it serves but to mar or render gaudy where it should only brighten. Yet, notwithstanding the great and early display produced by the Calceolarias, when the tardy Pelargoniums at length made growth and blossomed, the diversity of colour both of foliage and flower which is their peculiar property at once established their supremacy.

To be really enjoyable, a flower garden must not only be beautiful as a whole, but the beds must be interesting when looked upon individually; and it is from the numerous sterling sorts of Pelargoniums that we obtain materials with which this effect may best be produced. As far as I have been able to judge, many of the old varieties are still unsurpassed. For producing a rich and dazzling mass of bright scarlet, of Cybister it may be said that it has "no superior, nor yet an equal." In a comparison of its merits with Lady Constance Grosvenor, the latter, in sporting parlance, is "nowhere;" its habit is certainly very fine, but in these days of massing, abundance of blossom must rank first. Plant Cybister thickly, and its thin growth ceases to be a blemish.

Stella, Minimum, Amy Hogg, Waltham Seedling, Provost, Lord Palmerston, and Christine have all been very fine. One question which constantly presented itself to my mind during the past season was, Is Christine yet beaten? Maid of Kent is unquestionably a fine variety; its growth is sturdy and compact, its trusses are large and abundant, and its deep pink tint is unrivalled; but it has just one fault that spoils all these advantages, and that is, that its flower stalks are so long that its trusses, instead of just nestling in or being slightly elevated above the foliage, are borne above it in so high and irregular a manner as to quite unfit it for small beds. Perhaps others who have cultivated it will kindly offer their opinion of its merits. Another excellent kind which has been very fine is St. George. It is a strong grower, but its very deep scarlet flowers are quite distinct from those of any other variety. Dr. Hogg, too, is a splendid kind, of good habit of growth; the truss is large and handsome, resembling Amy Hogg, but the flowers are broader in petal and deeper in colour. Violet Hill is the best cherry-coloured Nosegay Pelargonium I have ever

grown; it is dwarf and compact, with abundance of finely formed trusses, and is first-class in every respect. Éclat is evidently closely allied to Le Grand, which it very strongly resembles both in its growth and flower truss, but it is of a much deeper shade of colour. It is a desirable variety. Blue Bell is of strong growth; its trusses are large, and its singular colour, a bluish pink, gives it a distinct and striking appearance. Next comes the beautiful Glory of Waltham with its deep rich glowing crimson scarlet trusses, which are large and compact; its very deep colour, together with its plain green foliage and spreading habit, tend to make this a distinct and excellent kind. It is superior to Crimson Queen, to which its flowers are very similar. Grand Duke is a bold, striking, and splendid variety, having immense trusses of orange scarlet; the flowers are very large, and the habit is moderately vigorous. Next this La Peyrouse may worthily occupy a place, for it is a splendid variety, moderately strong in its growth; its extremely large trusses, which render it so conspicuous, are produced in sufficient abundance to make it a valuable bedding plant. The colour is an intermediate shade between Rebecca and Provost.

Among broad-petaled scarlets, several kinds of nearly equal merit claim notice. Lord Derby, Ardent, Scarlet Circle, and The Clipper are all equally good, all producing fine large trusses, with flowers of exquisite form, and bold and handsome foliage. A bed of The Clipper has been very beautiful, and I am inclined to yield precedence to it for that purpose; the flowers of Ardent are rather larger, but its habit is scarcely so good, nor is it equalled as a bedder by Lord Derby, with which it has been grown side by side. Some beds of the old variegated Manglesii, alternating with others of Purple King Verbena, had a good effect. A new and meritorious sort resembling this old favourite, is called Duke of Edinburgh.

It will, I hope, prove useful to conclude these notes with a selection of one or two first-class kinds in each section.

Taking zonal Pelargoniums first, we have Faust as a strong-growing scarlet, The Clipper of medium growth, and President Reveil as a splendid dwarf kind. Among the lighter shades of scarlet, Provost is too good to be left out, and for producing a rich bright mass of orange scarlet Grand Duke has no equal. Of bright pinks, Christine, Maid of Kent, and Blue Bell will suffice. And then amongst Nosegays the brightest of all bright scarlets is Cybister, and for a strong-growing, deep, rich scarlet St. George, and Violet Hill for a lake rose or cherry colour; while either Lord Palmerston or Minimum will please as light crimson shades. No finer deep crimson can be had than Glory of Waltham, or a brighter rose colour than Dr. Hogg.

Of kinds grown for the effect of their foliage nothing can be better than Crystal Palace Gem for a yellow, and Castlemilk for a white leaf; and from the multitude of kinds known as gold and bronze, Her Majesty may be chosen for its broad handsome zone, and Beauty of Ribblesdale for its narrow zone and fine bright yellow colour. Of Golden Tricolors, Lady Cullum and Louisa Smith will be sure to please, the first by its richness as a mass, and the second by its very large bold foliage and free growth. Of Silver Tricolors I shall say nothing as bedders; but for pots, Glen Eyre Beauty, Italia Unita, Queen Victoria, and Impératrice Eugénie are all distinct and good.

My object in offering so short a list is to render it useful to those who may require a few choice kinds, and in making the selection I have been obliged to pass over many of my favourites, but of those chosen I have no hesitation in saying that they are the cream of a collection of several hundred varieties.—Edward Luckhurst, *Egerton House Gardens, Kent.*

PROPAGATING PLUMBAGO CAPENSIS.

Seeing in your last number an article on Plumbago capensis, signed "C. A. G., *Ealing*," in which some details as to the plant's propagation are desired, I feel much pleasure in communicating my simple method of producing plants. When I received my plant I was informed that I could only propagate it by suckers. Having had my plants for nearly three years without producing a sucker, and thinking it necessary to prune it last spring with the idea of getting it into better shape, I took care of what I cut off, selecting from the prunings four which had new shoots from 2 to 3 inches long. These new shoots only I put into a pot of good mould with which I mixed a little silver sand, covering them with a tumbler-glass, and giving them a little water to prevent them from drooping. I placed them in a shady part of my little greenhouse for a few days, and then exposed them to light and sun, taking care to supply them with water that they should not flag. I kept the glass on until I saw they were growing, only occasionally taking it off to give a little fresh air for a few minutes. I have now four plants, two about 6 inches high, and two fully 1 foot high, and branching. I shall repeat the experiment next spring, as I am very fond of my plant. The flowers are exceedingly pretty and delicate.

Having no convenience for a hotbed or bottom heat, I generally succeed in growing plants by this method.

I am indebted to your correspondent for the information as its being half-hardy, which will enable me to plant it in the garden for the summer months.—T. H. W., *Bristol.*

ORCHARD-HOUSE CROPS.

In a season of failure generally, the orchard house has again given us a good crop of fruit. This most assuredly must be attributed to the house being heated; at the time the trees were in flower, the weather was most unfavourable to the setting of the fruit. Continued low temperature, if the air is dry at the same time, is not so injurious, but the atmosphere was charged with moisture as well, so that it was necessary to have the house warmed artificially by day as well as at night. The fruit has been very fine; this year Peaches and Nectarines are the principal crop, but a few of the finer varieties of Pears are grown; all of them are in pots, and are now moved out of doors in order that the house may be filled with Chrysanthemums, so that as soon as the interest in the trees ceases, the interest in the flowers begins.

There are still gardeners who are averse to orchard houses, and some of the correspondents of the Journal are not favourably impressed with them. I think a garden incomplete without an orchard house, it is quite as good as a Peach house for growing Peaches and Nectarines, and very much more interesting, owing to the greater facility with which the trees and fruit can be examined, and the greater number of varieties which can be grown in the same space. Trees cultivated in pots require a greater amount of attention as regards watering, but the expense of wiring the house and training the trees to the wires afterwards is avoided. Pears are also grown to great perfection in pots in the orchard house. Some cultivators advise moving Pear trees out of doors to ripen their fruit, but I have not obtained fruit of such good quality by doing so; the best Pears are those ripened under glass.

I weighed some of the fruit this year from the pot plants; the Summer Beurré d'Aremberg (Rivers) were very small, four of them weighed 12 ozs.; three fruit of Williams's Bon Chrêtien weighed 1¼ lb.; and three Beurré d'Amanlis, 1 lb. 11 ozs. Madame Treyve is a free-bearing Pear, the fruit juicy, and of an agreeable flavour, four weighed 2 lbs. 7 ozs. Louise Bonne of Jersey is one of the very best Pears for orchard-house culture, it is always full of blossom-buds; four of the fruit weighed 2 lbs. 7 ozs. Beurré Diel is also an excellent variety, it is of good flavour, and the largest of dessert Pears; one of the fruit weighed 18½ ozs., and three together were 3 lbs. 1 oz. General Todtleben is a very fine Pear, but it is not a free-bearing variety. I have had fruit of it weighing 18 ozs.

The Peaches and Nectarines ripened earlier than usual. Early Beatrice Peach is the earliest now; it ripened on the 1st of July. This is a useful variety, although it is only of medium size; it is a good-flavoured Peach, and keeps pretty well after it is ripe. Early Rivers ripened on the 8th of the same month; this is also of medium size, the flesh is very melting, and the fruit decays directly it is ripe. Hunt's Tawny Nectarine did not ripen until the 20th. This is the earliest Nectarine here; it is a very useful sort, but very much subject to mildew. This can only be kept under by repeated dustings with flowers of sulphur. Early Grosse Mignonne Peach was the next to ripen on the 21st, succeeded by Dr. Hogg and Royal George on the 24th. In the first week in August, I picked the following varieties of Nectarines—Downton, Cricket, Murray, Rivers' Orange, Violette Hâtive, and Balgowan; of Peaches—Grosse Mignonne, Galande, Bellegarde, and Violette Hâtive. Prince of Wales and Victoria Nectarines ripened about the middle of August; these two are the latest Nectarines.

There are some good late Peaches to select from now, and some of them set their fruit much more freely than Late Admirable. Walburton Admirable is also a very fine Peach, but shy in setting its fruit. Another very fine late Peach is Ex-

quisite, an American variety; it has yellow flesh; it is also rather shy in setting its fruit. Mr. Rivers has raised some very fine late varieties. Prince of Wales succeeds the mid-season varieties; it sets its fruit freely, and is a very useful variety. Princess of Wales has large flowers; the fruit sets freely, is of large size, and of excellent quality. It ought to be in every collection; it ripens after Prince of Wales. Lord Palmerston bore half a dozen fruit for the first time here this year. Mr. Rivers describes it very truly. "Very large, the largest of Peaches; skin creamy white, with a pink cheek; flesh firm yet melting, very juicy, and rich. Flowers very large and beautiful." It ripened with Princess of Wales, and is slightly a clingstone. The last Peaches to ripen were Comet and Salway; they ripened about the same time, and have a great resemblance to each other; both are yellow-fleshed, melting, and good.

I can say very little that is new about cultivation. It is a good plan to have the trees potted early. I pot them directly the fruit is gathered, so that they make fresh roots in the new soil before the leaves fall. Overpotting is to be avoided, but the soil must be very firmly rammed in.—J. Douglas.

GRAPE VINE CULTURE IN CEYLON.

We are informed by a gentleman just returned from Ceylon, that there the Vines are taken up annually, great care being necessary to avoid breaking the roots, this operation being best performed by grubbing away the earth with the hands. The roots are then exposed to the full rays of the sun, until the leaves shrivel and fall. The Vine is then cut down, and replanted in fresh soil. The time, as far as he remembers at present, for exposing the roots to the sun, is at the end of the dry season, when there is not so much sap in the wood—this would correspond to our autumn, preparing to a certain extent the plants for the shock of the frost—in the tropics of the sun.

THE COCKCHAFER GRUB, THE "VER BLANC" OF THE FRENCH.

Your correspondent, "Y. B. A. Z." (page 307), must have but a very slight acquaintance with this very troublesome pest in our gardens, else he would not have written as he has done respecting it. "R. F." and "D., *Deal*," are both right in saying that it feeds on the roots of plants; there is no question at all with respect to that. "Y. B. A. Z." says "he has never found it in garden soil." Well, neither have I very often in this country. Let your correspondent visit France, however, and see the wholesale destruction which it there causes, both in fields and gardens. Very few plants are safe from its depredations. Not only grass, but all sorts of vegetables, also fruit trees, young Coniferæ, and Rhododendrons, especially the last-named, the young roots of which and the bark the grubs peel off quite to the surface of the soil. Vast sums of money have been expended in France on their destruction, yet with no apparent diminution. They are becoming a perfect curse. Long may your correspondent, and many others in this country, live in their present blissful ignorance, and be spared a more intimate acquaintance. Hear what Mr. Spinks (late of Chiswick), the very intelligent gardener at the Château de Chantilly (Oise, France), says on this subject: "In this country the insect, and its grub or larva, act as a complete plague to almost every species of vegetation, and large sums of money are annually expended in its destruction, but still it seems as plentiful as ever. Last year was noted for the quantity of the perfect insect (*hannetons*), and this year for the grub (*ver blanc*). Although the former commits great ravages upon the leaves of trees, especially the Oak, it is the latter that is most dreaded. As an example of their numbers, I may state that I was witness to the digging up of a piece of lawn, not more than 5 yards square, wherein were found 1600 of these grubs; the roots of the grass were all eaten off, and the dead and dying turf could be skinned off as if cut with a turf-cutter. They prey upon the roots of our fruit trees and Rhododendrons, which are destroyed in great quantities, and, indeed, nearly all sorts of flowers and vegetables. Lettuces have for them a great attraction, so much so, that they are grown and planted in our flower beds, &c., as traps for these pests. The grubs invariably attack the soft succulent roots of the Lettuces before anything else, which soon tell by their appearance of the marauders' visits. With the aid of a little stick they are soon discovered close to the root and destroyed, and another bait planted. In this way only, by continued perseverance in hunting them up, can we battle against our enemy or keep our plantation perfect.

"With respect to the destruction of the perfect insect, we find the best plan is to shake the trees or branches every morning, when the insects will fall in great quantities to the ground, and may then be swept up and destroyed by pouring boiling water over them. Pigs and fowls devour them greedily, but it is said to give the flesh of the former, and the eggs of the latter, a very disagreeable taste. This, however, I cannot vouch for."

I think this is evidence sufficient to convince "Y. B. A. Z." that these grubs do eat roots, and are, without doubt, one of the greatest scourges gardeners have yet had to contend with. —Archambaud.

APPLICATION OF MANURES.

On page 342 I see a notice of an article of mine by Mr. Graves. When I read it I thought it was by Mr. P. Grieve, and seeing it was intended as an answer to me, was surprised to find it was anything but an answer. Hard-headed Scotchmen have generally a reason to give for their opinions, and I read it through, hoping to see some good reason to reconsider the question. It is anything but disagreeable to me to be convinced of error, and I hold it no proof of superiority to be able to say I never change an opinion once formed. If truth is our object, new light on any subject ought to be welcomed. When I saw an editorial note at the foot of my paper that some difference of opinion with what I had written existed, and inviting discussion, I expected we should certainly have a consideration of the whole subject of manures and their application, which would be both interesting and instructive.

An argumentative reply is a compliment to any writer, because, however severe, it at least presupposes the paper worth an answer. A mere *ipse dixit*, except as to fact, is not so satisfactory.

I shall not review the whole subject till my previous arguments are answered, because those interested can read the article, page 221, and recapitulation will not give them force; but I will answer as well as I am able Mr. Graves's question, Why I consider the popular ideas on the subject of manures lead to injurious practice?

As long as persons think that fresh manure or fermented manure loses much of its strength by being thinly spread on the ground it is intended to enrich, manure will be treated in much the same way, whatever the nature of the land or kind of crop it is intended to benefit, or whatever the season in which it is applied. Those who wish to grow good Turnips on light soil know by experience they must use manure in a moist well-decomposed state; to expect to grow Turnips above dry unfermented manure would be as reasonable as to sow seed on a truss of dry hay. To obtain manure in a fit state for Turnips, the farmer of sandy land submits of necessity to a certain loss. It is impossible to ferment manure in large heaps without any loss, though with proper precautions that loss might be much reduced in amount. Who has not seen black streams running from a manure heap? How few know that such streams are not merely the water which was held in the manure, but in many cases are formed of what was once the solid manure itself, some of the results of fermentation being carbonic acid and water? Though by the intermixture of layers of soil in the heap much loss might be prevented, still the fermentation of manure is, I think, in this case, though necessary, a necessary evil. But for strong soils decayed manure is not a necessity. Unfermented manure keeps such soils open; and as strong land of good quality will retain manure for any length of time, no loss can be sustained, however long the time between its application and the sowing of the crop it is intended to benefit. Besides, all gases in a nascent state—that is, recently released from their combinations, unite with greater energy: therefore new compounds are more readily formed between the elements of the manure and those already in the soil. For these reasons I think it an unnecessary and useless waste of manure to ferment it in heaps before putting it into strong soils, and would prefer its being decomposed in the soil, which seizes with such avidity gases given off by decaying animal and vegetable matter. But supposing I have a field of strong soil which wants manuring, that there is plenty of good dung ready to be carted upon it, but the land is so hard and dry that no plough will enter it. If I believe that manure will be injured by sun and wind, and that to prevent serious loss it is necessary to cover it up at once, of course the idea of spreading manure under these circumstances will be dismissed. What generally happens in such a case? The manure is either left

in the yard, or more generally carted into a heap just inside the gate of the field for which it is intended. If left in the yard it is well placed to receive a good supply of water when the first heavy rain falls. Part of this water, after passing through the manure and being well impregnated with its valuable saline matter, will find its way into the nearest ditch or into a neighbouring horsepond; the remainder, held in suspension by the manure, must be carted as an additional and useless weight into the field. The loss in a well-made heap will be less than in an open yard, but it is generally considerable. The loss of saline ingredients is attested by the fact that for years corn is spoilt, being laid and mildewed where the manure heap stood, and often for a considerable space around it. That there has been a loss of gaseous matter during the fermentation and spreading of the fermented manure, few will deny.

Now, if the idea that unfermented manure spread thinly over a field in dry weather can be injured by sun and wind be erroneous, surely it requires little argument to prove the erroneous idea mischievous. If it has caused me to reduce considerably the bulk of what is mechanically useful in opening clay soils, if the manure has been lessened in value by the loss of saline matters and valuable gaseous products, if in place of carting dry and light manure on dry land I have carted wet, heavy manure on wet land, surely my horses, carts, men, land, and pocket have been sufferers by the mistake. In the case of the heaped manure twice filled and twice emptied, the increased labour incurred is very obvious.

To prove an erroneous idea mischievous, will by many be considered labour lost. Is it not always so? The question is after all, Is it erroneous? I have in my previous papers tried to prove it to be so, and there has not been yet any attempt, either on the part of our friends the Editors, or any of their correspondents, to refute the arguments advanced. It cannot be that the subject is unimportant to horticulturists, though it has been considered with reference to agriculture. Why, then, this reticence? Having to the best of my ability stated my view of the subject, I think those who take a different one ought to give us their reasons.—J. Pearson.

[With the statements relative to the preparation and application of manure contained in this communication we for the greater part concur, but we do not concur in the recommendation implied in our correspondent's statement at page 221, that he had acres covered with manure as dry as wind and sun can make them. He asks, "What has it lost besides water?" We reply that it has lost much more. If the manure had been either fermented or was impregnated with urine it lost by such exposure to the sun and wind ammoniacal compounds and carbonic acid, which would have been absorbed and retained in the soil if the manure had been ploughed in as soon as it was spread. Top-dressing is the only mode in which solid manure can be applied to grass land, but if it could be applied in a liquid form so as at once to be absorbed by the soil it would save much of its valuable constituents from being passed away in the air. That this waste happens to a great extent in the case of sheep droppings is certain. If they could be collected, made into liquid manure, and applied in that form to the soil, much waste would be avoided. We are of opinion that the most economical practicable mode of preparing and applying stable manure is to allow it to decompose in brick-lined pits, covered over thickly with earth, with wells to receive the drainage; that some of this drainage should be poured over each load as it is taken to the place to be manured, and that the manure be dug or ploughed in the day that it is carted on. Fresh guanos—that is, the excrements of seafowl, are richer in ammoniacal salts than those long exposed to the sun, just as fresh pigeons', sheep's, and fowls' dung make a liquid manure richer than do similar quantities of the same dungs when old. In considering stable or farmyard manure, we must remember that its most valuable constituent is the urine of the animals who formed it, and that most of the ammoniacal constituents of that urine are dissipated by exposure to the sun and winds; whereas they are all absorbed and retained by the earths of the soil if covered by it. We have not published our opinions before—opinions sustained by Davy and Professor Johnston—because we wished to hear from practical men the results of their experience—Eds.]

IS THE POTATO DISEASE HEREDITARY?

In No. 422 of The Journal of Horticulture you inserted a few lines from me relating to the Potato disease under the above heading. On the 14th of last April I planted twelve good Potatoes of the same late kind; the produce, dug October 15th, was 201 Potatoes of all sizes, twelve of them diseased—a small per-centage, but enough to create a doubt. It appears that all kinds of late Potatoes are more or less diseased; therefore I shall try again next year by planting them four or five weeks earlier.—W. Kerl.

STOKE NEWINGTON CHRYSANTHEMUM SHOW.

The twenty-third annual Show of the Stoke Newington Chrysanthemum Society opened yesterday at the New Assembly Rooms, Defoe Road, Stoke Newington, and will be continued this day. It well maintains its reputation as the mother of the Chrysanthemum shows round London. The specimen plants of the large-flowering kinds are especially good. Mr. Forsyth, of the Brunswick Nursery, is first with fine specimens of Christine, Prince of Wales, Lady Harding, Annie Salter, Dr. Sharpe, and Mrs. George Rundle, the last very fine. Messrs. Drain, De Beauvoir Town, are second with White Christine, Alma, Dr. Sharpe, Prince of Wales, and Beverley. These, too, are very good. In the class for three plants Mr. Forsyth is also first with Mrs. G. Rundle, Dr. Sharpe, and Prince of Wales, all of which are excellent specimens. Messrs Drain are second, and Mr. Butcher, gardener to C. Ballance, Esq., Lower Clapton, is third.

With three Pompons, Mr. Howe is first with Bob, General Canrobert, and Cedo Nulli, each very well grown, and full of bloom. Mr. Forsyth is second with Bob, Golden Aurore, and White Cedo Nulli, also excellent; and Mr. North, of Lee, is third. The best six standards come from Mr. James, of the Rochester Castle, and also the best collection, Mr. Butcher being second.

The best six Pompons, and excellent indeed they are, come from Mr. Forsyth, and consist of Cedo Nulli, Golden Cedo Nulli, Lilac Cedo Nulli, Sainte Thais, Bob, and Andromeda. Mr. North is second, with large plants, but somewhat rough, and Mr. Monk, gardener to W. A. Smee, Esq., Woodbury Down, third.

Of cut blooms there is an excellent show, though perhaps the competition is not so keen as in former years. The best twenty-four come from Mr. Rowe, Roehampton, who has Mrs. G. Rundle, Dr. Brock, Prince of Wales, Princess Beatrice, Jardin des Plantes, Empress Eugénie, Antonelli, Lady Slade, White Globe, Golden Dr. Brock, John Salter, Lady Talfourd, Lady Harding, Gloria Mundi, Venus, Maréchal Duroc, Novelty, Plutus, Prince Alfred, Empress of India, Rev. J. Dix, and Cherub. Mr. Berry, Roehampton, is second.

For twelve cut blooms Mr. Berry, Roehampton, is first with fine examples of Mrs. G. Rundle, Lady Harding, Empress of India, General Bainbrigge, Jardin des Plantes, Prince Alfred, Queen of England, Venus, Cherub, Princess of Wales, Novelty, and Prince of Wales. Mr. Rowe is second with a very good stand. Messrs. Goddard and Beadle also take first and second prizes for stands of twelve blooms. The first prize for six was awarded to Mr. Howe, Shacklewell, Mr. Berry being second; and in another class for the same number the prizes go to Messrs. Beadle, Goodenough, and Goddard in the order in which they are named.

The best twelve large Anemone-flowered varieties are furnished by Mr. Rowe and Mr. Forsyth, who take equal first prizes; and for Anemone-flowered Pompons, Mr. Howe is first, Mr. Forsyth second, and Mr. James third.

In addition to the Chrysanthemums, Mr. Trushell and Mr. W. J. Smith contribute good Apples, Pears, and Nuts. Mr. James sends bouquets of dried flowers, as well as a Prickly Cayenne Pine Apple, Muscat Grapes, and Apples; and Mr. Heard, gardener to Mrs. A. Grosvenor, large Uvedale's St. Germain Pears.

Several new varieties of Chrysanthemums are shown, but these have all been noticed before, except a Pompon, called Cavoction, with large purplish rose flowers, which comes from Messrs. E. G. Henderson and Son, and which received a first-class certificate.

GROWING CELERY IN BEDS.

Having a large family to supply from a small garden, I am obliged to employ every means I hear or think of to increase the amount of its produce. This year, for the first time, I grew most of my Celery in beds 6 feet wide, with five rows in each bed, the soil of the bed being taken out 18 inches deep, and then replaced with a foot of good manure. Manure water was also copiously supplied during the summer. The plants were kept tied up, their suckers cleared off, and in due time they were earthed up. Now for the result: from first to last the two outside rows were much dwarfer and of greater substance than the others, which I ascribe to these rows being most exposed to the sun and air; while the three inner rows shot away at a remarkable rate. This being a new system in our part of the country, it was the admiration of all who saw it, and again and again I was called by my better-half to give the necessary information respecting it, and all pronounced the system a great economy. For myself, however, I thought this questionable, and when taking-up time came, the outside rows had thick, solid, crisp stalks, while the middle three

rows were anything but good, 3 feet high, and having thin, soft, pithy stalks, being upwards of not one-third so good as the others. Growing in a very moist soil and atmosphere, they are already rotting very fast. I fear if I had not acted with some precaution, and put in a few single rows before the turn of the day, I should have been without any Celery.

I have no doubt the bed system may do well in dry gardens, and I intend another year to modify the system of planting, as it is well worth a fair trial. I will have three rows instead of five, and plant a dwarf kind, such as the Incomparable. Thus, more air will be admitted to the middle row, which seems to be the great drawback. Although Celery delights in moisture, and to a certain extent in shade, it must have plenty of air to be good and stand the winter well. As I am not writing for any other purpose than to learn, I ask some of your readers who have succeeded in the bed system to give, through "our Journal," their experience.—J. T., *Maesgwynne, South Wales.*

CHRYSANTHEMUMS AT MR. FORSYTH'S, AND THE TEMPLE GARDENS.

Mr. Forsyth's Brunswick Nursery, Stoke Newington.—The display of Chrysanthemums in Mr. Forsyth's show house is always excellent, and this year it is better than ever. The plants are now in full bloom, and the mass occupying the centre of the house forms a beautiful sight, for though perhaps a little crowded, owing to want of space, the varieties are well distributed so as to afford a diversity of colour, and many of the blooms are remarkably massive. Conspicuous among these is Princess of Wales, a most beautiful flower, which is a favourite with everyone, the white being delicately tinted with lilac rose. Several blooms of this are quite 5 inches in diameter. Empress of India and White Globe, also white, and Prince of Wales, purplish violet, have splendid blooms equally large. The following are also very fine:—Rev. J. Dix, St. Patrick, General Harding, General Bainbrigge, John Salter, Ali Babi, Golden Beverley, Jardin des Plantes, Gloria Mundi, Aureum multiflorum, Prince Alfred, Lord Derby, and Virgin Queen, the purest of whites. Mrs. Heale is another very fine pure white flower, a sport from Princess of Wales, which it resembles in all but its colour. Mrs. George Rundle, though not equalling the preceding in the size of the flowers, fully maintains its character for free-blooming, and forming admirable specimen plants, and for this purpose Dr. Sharpe is equally good in its colour. Of both of these Mr. Forsyth has large specimens grown so evenly and well, and so abundantly covered with flowers, that even he may be proud of them. Somewhat resembling Dr. Sharpe in colour is a seedling with larger flowers, which is very promising. Princess of Teck, delicate blush, is a finely incurved flower of last year, and another very pleasing but older variety is Empress Eugénie. We also noticed Isabella Bott, white tinged with lilac; Enamel, delicate blush; and Miss Mary Morgan, a new delicate lilac, broadly incurved kind, first shown last year at Stoke Newington. Mr. Evans, Mr. George Haskin, and Blonde Beauty, new kinds sent out in the spring of this year, are coming forward, but have not yet attained perfection.

Fine specimen plants are placed on the side shelves in the show and other houses, consisting of Mrs. G. Rundle, Dr. Sharpe, Defiance, Annie Salter, &c.; and among Pompon kinds, the different colours of Cedo Nulli, Sainte Thais, Andromeda, and Golden Aurora, are represented by admirable specimens. Several of the large-flowered Anemone varieties, as Madame Godereau, Gluck, &c., are particularly fine this year, and interspersed among the mass of incurved varieties in the show house are some of the showy Japanese varieties, serving to increase the diversity of form and colour. The Daimio, Red Dragon, and Comtesse de Beauregard are very bright and effective.

The Temple Gardens.—Mr. Broome, in the Inner Temple, has an unusually good display, and to the varieties printed names are attached. This adds much to the interest of what has become one of the sights of London, and which, be it remarked, is visited by thousands of all classes. Chrysanthemums about London are generally very good this year, and Mr. Broome grows so many, that to give the names of all the varieties which are well represented would occupy a large amount of space. We must therefore confine ourselves to mentioning, as a few of the best, Lord Derby, Mrs. G. Rundle, General Slade, White Globe, Beverley, Vesta, Golden Hermine, Jardin des Plantes, Guernsey Nugget, Golden Eagle, Prince of Wales, Prince Alfred, Nil Desperandum, and Progne, the last, which is most brilliant in colour, being freely introduced, especially in the back row. Several of the new Japanese varieties seem also to be very attractive to the public. In the beds on the lawn the Pompons are in good bloom, especially the different colours of Cedo Nulli, Aigle d'Or, Salamon, and Aurore Boréale.

Mr. Dale, in the Middle Temple Gardens, has also a show of Chrysanthemums, though much less extensive than Mr. Broome's as regards the large-flowering kinds. Of these Gloria Mundi, Venus, Beverley, Mrs. G. Rundle, and Cherub are the best. Marabout, white, with fringed florets, is very pretty. The large circular beds of Pompons are excellent, the kinds consisting of White and Lilac Cedo Nulli, Aurore Boréale, Duruflet, Drin Drin, Madame Pépin, Général Canrobert, and one or two others, together with Mr. Murray. There are also two good banks of these and other kinds.

BRICK EDGINGS FOR GARDEN WALKS.

I was glad to observe in the columns of your instructive Journal, your recommendation to "A. B.," of Mr. Robson's mode of forming an edging. Permit me, therefore, to add my testimony in corroboration, as I adopted it about three years since, and although as yet on a somewhat limited scale, still sufficiently to confirm my good opinion of its merits and worthiness of unlimited adoption, combining, as it does, the useful and ornamental, especially when the edging is constructed of dark blue Staffordshire bricks. These may be coated with stone-coloured paint brushed over each alternate angle, with a little white sand sprinkled over it, to deaden the gloss of the paint. This produces a very pleasing and decided effect, the paint will remain in good condition for several years, and its cost is almost nothing. The uninitiated are invariably puzzled prior to inspection as to the composition of this kind of edging, entertaining the idea that it is terra-cotta. At the terminations of each line of edging, I insert one of the bricks vertically, thus forming a suitable and substantial finish to the bricks set obliquely.—W. Gardiner.

SOLANUM CAPSICASTRUM CULTURE.

Your correspondent "G. H.," page 349, wishes to know when to sow Solanum capsicastrum, and likewise, I suppose, how to grow it afterwards. I have plants averaging 18 inches high, 16 inches through, and having on each a hundred berries, which are just changing colour, contrasting beautifully with the dark green foliage, which is seldom seen when the plants are grown in the usual way—*i.e.*, in pots throughout the summer.

Sow about the middle of February in light rich soil, and place the pots in a temperature of 60°. As soon as the seedlings are large enough to handle prick them off into pots or pans at about 1½ inch apart. When they begin to be crowded, pot them off singly in 3-inch pots. Keep them in the same temperature until they are well established in their pots, and then gradually harden them off, the same as you would bedding plants.

About the latter part of May plant them out in an open piece of ground 18 inches apart each way. All the attention they require during the summer is to keep them free of weeds, and if the weather should be very dry give a good soaking of water occasionally. About the end of September lift them carefully, and pot them in some rich loamy soil, adding a good portion of river sand to keep the soil open. Pot them firmly in large 32-pots, set them anywhere in the shade out of doors, and give them a good soaking of water at the roots, and frequently sprinkle them overhead until they are established in their pots. They may then be placed in the full sunshine, and afterwards removed to the greenhouse, where they will make a fine display all through the winter and spring months. Larger pots can be used, but not smaller ones, as they cramp the roots too much. I was obliged to pot mine in small 32's, as I grow them chiefly for table decoration, and larger pots would not go into the vase that is used.

Solanum pseudo-Capsicum may be treated in the same way, with this exception—it requires to be stopped when about 2 inches high, otherwise it will be a foot or 15 inches high before it begins branching, and will have the appearance of a standard.

It is necessary to feed the plants with liquid manure when

they become established, otherwise the heavy crop of fruit will exhaust the plant and cause the leaves to turn pale.—W. Hills, *River Mead House, Sunbury, Middlesex.*

PLATYCERIUM (ACROSTICHUM) ALCICORNE.

I have often been surprised that this gem is not more extensively grown; it is of very easy culture, has a very pleasing appearance, and with a little attention amply repays one for the time bestowed on it. I have seen it growing on a small piece of board. I grow mine on small roots; some I hang up, and I place one here and there about my stove. I have one very large specimen. I obtained a large Alder root—it filled a large barrow; this I filled with sphagnum moss, peat, and cocoa-nut fibre; I then planted small plants over it, and they now form a beautiful object. The lovely fronds and the large frill are very novel. Here and there pieces of the root projecting, covered with moss, add greatly to the beauty of the whole. When showing anyone round my stove I have often heard the remark, What a lovely Fern! It never fails to be remarked, having such a striking and chaste appearance. I think when plants of it are placed here and there about our stoves they serve as a relief to other subjects. Growing, as it does, on the root, it looks more like nature. The Stag's-horn Fern is an old favourite of mine, and I think no collection of Ferns complete without it.—F. P. L.

VINERY HOUSE, ALLERTON.

(*Concluded from page* 362.)

We now come to the boiler house. It is large and lofty, and situated in the angle formed by the houses on the left, which I have endeavoured to describe, and those which extend directly south-west from the boiler-house 320 feet. Here we have two "double-tubular boilers with cylindrical water-jacket furnaces," heating 6000 feet of 4-inch piping; and that they are kept going is evidenced by the fact that Mr. Clarke forces so as to have Grapes and Peaches ripe in May. Mr. Pearson should come and see these two boilers; he would not have said, when writing of tubular boilers, "I would not have one for a gift." I have tried more than one kind of tubular boiler, had replaced by tubular boilers those which our "best gardeners give preference to," saddle boilers or modifications of them, and found one tubular boiler heat as much piping, or give as much heat, as half a dozen fires required for the others. The most efficient boiler I have used is that form of the tubular boiler with the water-jacket, which gives it a great advantage over all tubular boilers, and I may say every kind of boiler. This boiler is of Mr. Clarke's invention. The two have been in use some time, and are of the kind known as "No. 3, double tubular," price £30. That they do their work satisfactorily was evidenced by what I saw in the houses, and for economy in consumption of fuel they are unequalled, as Mr. Clarke's coke account plainly shows. The cost for coke is £10 per year, or on an average £10 per quarter. From this we must deduct for coke consumed in the house, kitchen, gardener's cottage, by the boiler for steaming food for the horses in winter, and by the boiler in the cellar which heats the 800 feet of 4-inch piping in the conservatory, greenhouse, and house, which piping is independent of the 6000 feet attached to the two boilers; for these items I cannot say less than £10, so that the two boilers heat, to boiling point if necessary, 6000 feet of 4-inch piping, at a cost of £30 a-year.

The boiler house was in good order, and not a place for rubbish and dirt as one not unfrequently finds it. Outside the boiler house a large tank was pointed out that takes the water from the roofs, it being made large enough to hold a sufficient supply to last through the summer. Some idea of the water required may be formed, when it is stated that one of the Vine borders alone requires 800 gallons each time it is watered. None but rain water is employed for watering purposes. It is to be regretted that all proprietors of gardens do not make provision for collecting the rain water from the buildings, so as to leave no excuse for allowing plants to wither and die, or the leaves to become covered with insects, owing to the want of a proper supply of water.

Adjoining the boiler house is the stove. It has a central bed, with hot-water pipes for furnishing bottom heat, a good wide shelf in the front, and a walk at back and front, and I noticed the same liberal amount of piping as in the other houses, which certainly is an example that might be advantageously followed. The back wall and part of the roof were covered with that best of all stove climbers, Stephanotis floribunda, and Ipomœa Horsfalliæ, whose rich crimson flowers were very attractive. There were also splendid plants of the sweetest-scented of all flowers, the double-blossomed Gardenia florida, clustered with buds, and having bright and shining foliage; and G. Stanleyana, in flower. These plants are not half so much grown as they deserve to be. Good plants of Clerodendron Thomsonæ, trained to a sort of upright conical wirework, were in flower, the rosy purple flowers contrasting well with the cream-coloured bracts. Franciscea confertiflora or laurifolia, with handsome foliage, struck me as being very different from the ill-formed straggling plants generally seen, with foliage devoured by thrips and scale. There were Allamandas, Ixoras, and many other kinds of plants of merit, but I had not time to note them.

Next to the stove is another early vinery 52 feet long by 20 feet wide, having a border similar to those of the other two vineries, it being made both inside and outside the house, chambered, and having hot-water pipes beneath it. The wood of the Vines was very hard, and the buds very prominent. These Vines had long been at rest, and from the appearance of the buds it would have been no difficult matter to have started them to ripen the fruit in January, but Mr. Clarke does not wish to force so early, as he can keep the late sorts in good condition until May, when the early houses yield fruit. The varieties are principally Black Hamburgh and Golden Hamburgh, with a few Buckland Sweetwater and Trentham Black. The Golden Champion is also here under trial. The house was crammed with pot Vines of late sorts, such as Lady Downe's, Alicante, and Barbarossa, which Mr. Clarke fruits extensively and successfully in pots.

The late vinery is 52 feet long by 20 feet wide, and its border is vaulted like all the others. It extends both outside and inside the house, and is heated by nine rows of hot-water pipes beneath, and there is the same number of pipes for top heat. The border is entirely above the path, which is at the back of the house, and on the parapet or wall keeping up the soil of the border are grown Vines in pots, a row of them as close as the pots will stand touching each other, and the canes being trained upright. On the other side of the path, against the back wall, is another row of Vines in pots, the pots resting on flags, which form the cover of the passage for the hot-water pipes that go through these houses to the Peach houses beyond. Small openings in the sides of the passage regulate the heat according as it is required for warming the flags, so as to give bottom heat to the Vines, or to admit heated air to the house. The Vines on the sides of the path are quite a sight, carrying from eight to thirteen bunches each, which, though not so large, nor with berries so large as those on the Vines in the borders, are perfect in colour, and large enough for a gentleman's table. The varieties were Lady Downe's and Alicante. In these pot Vines I noticed that the greater the number of bunches the smaller these were, and some Hamburghs had the inevitable red of an overcrop. The bunches of many would weigh more than 1 lb.

The permanent Vines were thriving exceedingly well, carrying a heavy crop, but not too heavy, as was evidenced by the wood they had made this year, and that being fully ripened. Mr. Clarke experiences no difficulty in doing this; from the warmth and raised border he has a perfect control over them. Barbarossa, an eye in 1866, carried two bunches, and had a cane 3½ inches in circumference, with eyes like nuts, and seeing their wood I do not doubt Mr. Clarke's statement, that he had last year a bunch of this kind 4 feet in circumference. This year, however, both Barbarossa and the Muscat of Alexandria have not done so well, owing, he says, to their not having had sufficient water last season. The Muscat and Barbarossa, Mr. Clarke finds, will not bear nearly so much drought as Lady Downe's and Alicante; or, in other words, the last two are not such gross feeders as the former two. When grown in the heated border, Mr. Clarke informs me that the Barbarossa, so far from having a thick skin, as it is often represented to have, has a skin as thin as a Hamburgh, and is a Grape he prizes highly, both for its keeping qualities and flavour.

Lady Downe's, an eye in 1864, is carrying twenty-two bunches of above a pound each, with large, well-swelled berries, perfect in colour and bloom, and notwithstanding the heavy crop the cane is very strong (3 inches in girth). Here, may I ask "R. M. W." if I understand him correctly, that the canes he writes about in his highly interesting and valuable article, page 219, are of the current year? the measurement referring to this, and not last year's wood. For a Vine to have "canes, three and four to a Vine—the Vines also with a crop—

16 to 20 feet long, and 2¾ inches in girth," seems incredible. I should also be obliged by being informed of the variety making such an extraordinary growth, not of length, but thickness of cane. Lady Downe's, notwithstanding Alicaute and Barbarossa having larger bunches, is, to my eye, by far the best; it has a noble appearance, and what is wanting in size is made up for in symmetry and finish. The Vine is also a great bearer. One of this sort planted in 1867, had in 1868 six bunches: this year it has thirteen. Too much cannot be said of this Grape; if the white sort be anything like it, it will be a boon indeed.

Alicanto is also precocious. A Vine from an eye in 1866 carries this year four bunches averaging 11 inches across the shoulders, and 12 inches in depth, splendid in colour and bloom. Trebbiano, also an eye in 1866, has two bunches; one 15 inches long, and 17 inches over the shoulders, the other 13 inches deep, and 17 inches over the shoulders. Muscat of Alexandria bears immensely, but the bunches are not equal in size to those of former years.

Mr. Clarke's opinion of the late Grapes runs thus—Lady Downe's first, it keeps so well; Barbarossa second; Alicante third; Trebbiano fourth; Muscat of Alexandria finest of all for flavour, but for keeping fifth; Black Hamburgh sixth.

There are other sorts, as Black Hamburgh, which ever since it fruited has had rusted berries, and it colours badly, which seems unaccountable, as all the others do so well. To all the vineries air is admitted in front through openings in the front wall, the pipes having a wrought-iron sheathing pierced with holes, there being about an inch cavity between the hot-water pipe and the plate-iron sheathing, and a sort of funnel, also of iron plate, connects the casing round the pipe with the openings in the wall. These are very useful for admitting air in dull and frosty weather, the cold air being heated before it enters the house by its coming in contact with the hot-water pipes. There is also front and top ventilation.

I have omitted Mrs. Pince; it is here succeeding well. Some write of it as a weak grower. It certainly is not a gross grower, but I have had an opportunity this season of seeing daily half a dozen of it, and one in a house along with Muscat of Alexandria, Alicante, and Black Hamburgh, and along with Foster's Seedling, Trovéren Frontignan, Buckland Sweetwater, and Black Hamburgh, and in both cases it has been the first to reach the top of the house or rafters.

There is an open apace between the last-named vinery and the Peach houses, in which are stored a number of Vines in pots for early forcing—put out, as it is termed, to harden, but in reality to induce rest. The Peach houses have the same aspect as the two vineries last named—viz., facing the south-east, and they are lean-to's, but the vineries have a short back light. The first Peach house is 84 feet long by 12 feet wide. The border is partly inside and partly outside, and in both instances above the ground level. It is 4 feet deep, and composed of the top spit of the ground about, a not very strong loam, and to this was added about one-sixth of marl. Six rows of 4-inch pipes serve for heating, the fruit being ripe in May. No manure was mixed with the soil, and no manure water is applied; and neither for Vines nor Peaches is Mr. Clarke any advocate of much manure in a solid or liquid state, and he attributes none of his success to manure. The trees were planted late in the spring of 1865. Mr. Clarke, having deferred it so late, had to be content with such trees as he could get. The result has been in 1869 the first prize for Peaches at Liverpool, and the first and second prizes for Nectarines, also the first prize at York for Nectarines. Some of his Peaches weighed 9½ ozs. The trees look as if they had been planted a dozen years. One Elruge Nectarine tree covers a space of 24 feet by 14 feet, and has a stem 1 foot 8 inches in circumference at the base, below the bud; and one branch, originated in 1865, is 9½ inches in girth. The trees and their foliage are in perfect health, no red spider—in fact, nothing deleterious to health, and though the red spider had appeared, it was speedily brought under, and also the scale, which ever keeps putting in an appearance, by a syringing with Mr. Clarke's compound.

Mr. Clarke practises what I may call the long-rod system of pruning and training Peach trees; indeed, he follows no particular mode of training, only it is a sort of fan, his object being to obtain fruit of good size and quality, and to cover the space in a short time. All the pruning they receive consists in cutting out the old and weak wood, and replacing it with new shoots, which receive no stopping as far as their leaders are concerned, but the laterals have their points pinched out at the first leaves, and they are kept closely pinched in to one joint. The shoots thus treated attain an immense length in a single year, some shoots of this year's growth being from 8 to 10 feet long, the whole length clustered with bloom buds. The trees grow so vigorously that they are crossing each other, though there are but seven trees in the house. The back wall is covered with them; but the trees there do not bear fruit, or very little, and the Castle Kennedy Fig on the back wall is equally unproductive. It grows very strongly, and no doubt its roots require to be more confined to induce fertility.

Next we enter a Peach house, 54 by 12 feet, corresponding with the last, but the growths are even more extraordinary. The trees were planted in 1866, and one of them has a 27-feet spread of branches, while a shoot of this year's growth is fully 10 feet long; but there is no unripe wood, and no lack of fruit buds for another year's production.—G. Abbey.

NOTES AND GLEANINGS.

There is at present to be seen in bloom at the Royal Horticultural Society's Gardens, Chiswick, that most magnificent of all Dahlias, Dahlia imperialis. The specimens are a little more than 12 feet in height, much branched, each branch terminating with a glorious panicle of from ten to twenty exceedingly beautiful white flowers, forming at this dull season one of the most splendid objects to be seen. We understand that it is to be exhibited at the next meeting of the Floral Committee on the 16th inst., so that our readers will then have an opportunity of seeing this magnificent plant.

REMARKS ON SOME BEDDING PLANTS.

Six degrees below freezing point on the night of October the 27th, and a fall of snow on the following day, suddenly brought the bedding season of the present year to a close, and as far as my experience goes, the unfavourable spring and the variable summer temperature have severely tested some of the more delicate kinds of bedding plants. Letters which reached me in July last, from some friends in the eastern and northern counties, informed me of the difficulty there was in inducing even the more hardy sorts of bedding plants to grow at all, and many were killed outright; while the planting of such tender subjects as Coleuses, Iresines, and Amaranthuses, was not attempted until the time arrived for a favourable season to have brought them into great beauty.

As the season has not proved one of the best, it may be both interesting and instructive to those who have not yet made their arrangements for another year, to give the accompanying plan of a flower garden which has come under my notice several times during the summer, with the description of the planting, adding a few notes on the merits or demerits of the materials employed.

Bed 1 was planted in imitation of a star having eight points, and the angles filled in with Lobelias. The bed is 20 feet in diameter, and the colours were remarkably effective, especially at a distance; but as the Lobelia is liable to become shabby early in autumn, and at its best is not effective when planted next the grass, I think a more distinct colour would have been better—say the old but beautiful Verbena venosa. I remember once seeing this bed planted thus—centre Centaurea candidissima, the star completed with Mrs. Pollock Pelargonium, and the angles filled in with Coleus Verschaffelti—a very lively and pleasing arrangement.

Beds 2 and 3.—Here the dark velvety brown of the Coleus in contrast with the bright and beautiful foliage of Mrs. Pollock, makes this a very effective arrangement for any flower garden. I have seen a bed this summer where the Tagetes signata pumila took the place of Mrs. Pollock in a similar arrangement, and I thought the orange, yellow, and brown-spotted flowers of the Tagetes improved the colour of the Coleus, and gave a better effect to the whole bed.

In beds 4 and 5, the bedding qualities of both the Perilla and Koniga are well known, but I may remark that the cerise-coloured flowers of Pelargonium Flower of Spring, peeping out from among the tufts of the Koniga, were thought an improvement.

If the old favourite in beds 6 and 11 possessed a better-shaped truss and more substance in the flower, so as to stand out more boldly, it would be an improvement; as it is, it is not easily excelled. Some complain that young plants of this Pelargonium never flower so freely as older ones. I experienced

the same failure until circumstances caused me to transplant a bed of them after they had made a good growth, and the result was an abundance of bloom and less foliage. Since then, if I find them becoming leaf-proud, I lift them with the spade, and plant again immediately, and beyond losing a few leaves the experiment has the desired effect.

Beds 7 and 10. This distinct species of Verbena appears to possess a charm of its own; the colour, a lovely violet, is not approached by any other inhabitant of the garden. It appears to increase in beauty as the autumn comes on. When pegged down at an early stage of its growth, it does not exceed 1 foot in height; and its small flowers supported on stiff flower-stems, withstand the wind and wet admirably, as the storm of September 11th did it no injury.

The Petunia in beds 8 and 13 grows too coarse and tall for such small beds, and in larger ones it is only attractive in fine weather. A storm soon disfigures its flowers, and towards autumn it is not in the least attractive. It is, however, a good plant for the background of mixed borders.

The Tagetes in beds 9 and 12 was grown as a substitute for the yellow Calceolaria, and in some respects it is a good one; it is a constant and profuse bloomer, even in the driest of weather, and in hot dry soils where the Calceolaria is so liable to fail, this plant is to be preferred; no wet or wind appears to injure it.

I now come to the mixed beds, which were purposely arranged to give increased effect to the five beds in the centre of the garden, and also those four beds in the centre of each of the two wings.

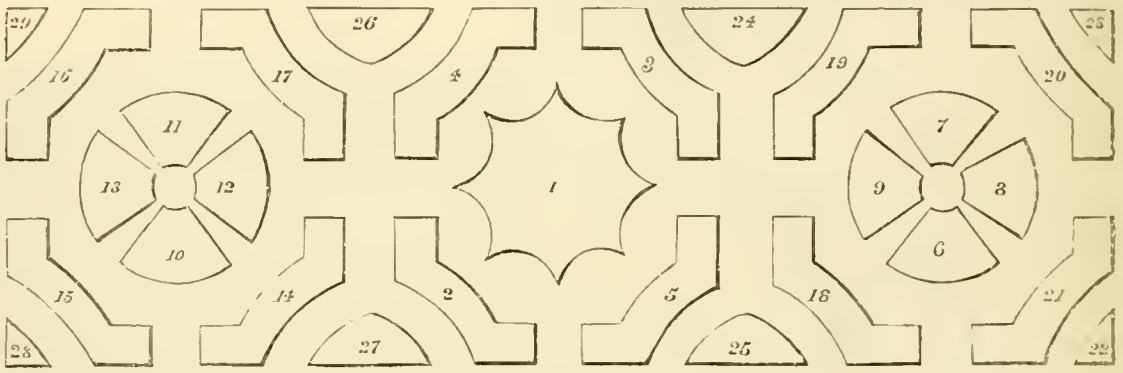
Nos. 14 and 16 have Pelargoniums Madame Rudersdorff, Cybister, and Rebecca, with here and there a plant of the Tagetes for centres, while the outsides have some of the dwarfer variegated Pelargoniums, such as Flower of Spring, Bijou, Lady Plymouth, and Crystal Palace Gem, with some dwarf Lantanas, as Lutea rosea, Alba grandiflora, Impératrice Eugénie, and Delicatissima.

In beds 15 and 17, the centres are occupied with the Intermediate Stocks, of many colours, which flower magnificently throughout August and the three following months, and for the outsides the pretty dwarf Victoria Aster, mixed Portulacas, and Lobelias.

Nos. 18 and 20, at the opposite end of the garden, contain Pelargoniums Indian Yellow, Cerise Unique, and Rebecca, with the white flowers of Mrs. Holford Verbena rising above the foliage of the Pelargoniums, as centres, while the outsides contain a mixture of Centaurea candidissima, Purple King Verbena, and Mrs. Pollock Pelargonium.

Nos. 19 and 21, Phlox Drummondi. These beds present a great variety of colour, which is effective and pleasing to the eye. To keep the Phloxes dwarf for small beds, they should be pinched once before planting out, and afterwards kept pegged down; they will then not exceed 1 foot in height.

The Pelargonium in bed 22 is a great improvement on Cloth of Gold; it is a vigorous grower, and is very effective both as



1. Centre Thuja aurea, surrounded by Iresine Herbstii, and a band of Centaurea candidissima, Lobelia speciosa next the grass. The circles surrounded by 6, 7, 8, 9, and 10, 11, 12, 13, also have Thuja aurea in the centre.
2, 3. Pelargonium Mrs. Pollock, edged with Coleus Verschaffelti.
4, 5. Perilla nankinensis, edged with Flower of Spring and Koniga maritima.
6, 11. Pelargonium Brilliant.
7, 10. Verbena venosa.
8, 13. Petunia nyctaginiflora.
9, 12. Tagetes signata pumila.
14, 16. Mixed beds.
15, 17. Ditto, ditto.
18, 20. Ditto, ditto.
19, 21. Mixed beds.
22. Pelargonium Crystal Palace Gem.
23. Lobelia speciosa.
24. Veronica speciosa variegata.
25. Pelargonium Rebecca.
26. Pelargonium Indian Yellow.
27. Stachys lanata.
28. Mrs. Holford Verbena.
29. Fuchsia Golden Fleece.

regards its flowers and foliage, its growth keeping close to the ground.

No. 23. This plant, so well known as a bedder, needs no remark.

The Veronica in No. 24 is one of the prettiest variegated plants in the garden, and should be more grown; it is very effective throughout the autumn, as it bears a few degrees of frost without injury.

The Pelargoniums in beds 25 and 26 are now so well known that I need not describe them, but I may just remark that Indian Yellow is one of the best flowering plants we have in the flower garden.

The plant in bed 27 should be more grown for its hardiness and dwarf habit, while its silvery lamb's-ear-like foliage makes it very attractive in the flower garden or shrubbery borders.

Bed 28. Of this and other Verbenas I cannot say much in their favour as distinct beddera; most of the varieties cease to be attractive much too soon for other plants. They are, however, very useful in mixed borders to supply cut flowers.

The Fuchsia in No. 29 has proved a failure with me. I could not with all my attention coax it into forming an attractive plant. It goes off very much in the same way as Pelargonium Cloth of Gold, for the plants appear to be less now than when first planted. It will grow in the shade best; even there it loses much of its leaf-colouring, which renders its flowers less attractive.

The effect of the whole arrangement, when viewed from either end, gave considerable satisfaction; but most of the beds being small (4 feet wide), the use of anything but dwarf-growing plants was out of the question. However, as the arrangement of the planting was on the cross-balancing system, every bed had more distinctness, which is always of importance in a design for small beds.

Of other arrangements that I have noted as worthy of imitation, was one in which the new Abutilon Thompsoni was used. The ground colour of the leaf of this plant is a bright green, which is beautifully mottled with yellow. It appears to retain its colours well when planted out, and grows with considerable vigour. Around it was a band of Amaranthus melancholicus ruber, with an edging of the pretty dwarf-growing Dactylis glomerata variegata. Another bed had Pyrethrum Golden Feather, dotted over with Lobelia speciosa.

There is another new introduction which I think will become a popular bedding plant—viz., the Iresine Lindeni. I think it the best of all the Iresines; the foliage is dark red, beautifully veined, and the growth being vigorous, the markings become well developed. I grew a few plants in common garden soil, fully exposed to the weather, and it proved so satisfactory, that I shall use it more extensively another season. The markings being only on the upper surface of the leaf, when the foliage in the sun is waving in the breeze it presents two or three shades of colour, which are pleasing to anyone.

Another valuable dwarf-growing plant is the Convolvulus mauritanicus; it appears to be quite hardy, and if allowed to

remain two or more years in one place it covers much ground and flowers most profusely. It may not be generally known that this makes an admirable pot plant. I once took up a few plants from the garden at this time of the year, potted them, and kept them in a cold frame until February, when all the old growth was cut off, and they were placed in the greenhouse on a shelf near the glass; they grew remarkably fast, and soon produced a profusion of flowers. They are most suitable for suspending where the shoots can hang at ease all round the pots.—THOMAS RECORD, *Lillesden, Hawkhurst.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHEEL manure upon vacant ground when the weather is suitable, and when it can be done without injuring the walks; also turn up all spare ground so as to expose it to the action of the weather. For land that has been long cropped with vegetables, a dressing of fresh loam would in many cases be preferable to manure, and where it is wanted it should be obtained, in order that advantage may be taken of frosty days for wheeling it upon the ground. Where fresh soil cannot be obtained, charred vegetable refuse, such as prunings of shrubberies and edgings of walks, may be cheaply made to form an excellent substitute.

FRUIT GARDEN.

Do not let Pears become overripe before being used; also look over the whole stock as often as time can be spared, removing any fruit that exhibit symptoms of decay, and put them aside for immediate use. Any of the choicer varieties of Pears that do not ripen properly in the fruit-room should be removed to a warm dry room for a few days; this will be found to greatly improve them. Keep all fruit as cool and dry as possible; if frost is excluded from the house the air can scarcely be too cool when the object is to preserve fruit plump and sound as long as possible.

FLOWER GARDEN.

Dahlias killed down to the ground should be taken up and placed roots upwards under cover to dry, preparatory to being stored for the winter. Chrysanthemums, which are everywhere flowering finely this season, must receive careful attention so as to preserve their beauty as long as possible. See that coarse-growing plants which may be encroaching upon their weaker neighbours are reduced so as to occupy their proper places. Valuable plants, as variegated Hollies, Rhododendrons, &c., if not growing as freely as it is desirable that they should do, would be benefited by a liberal allowance of rotten manure or well-decayed leaf mould applied as a top-dressing, covering it with a little fine soil, and working it into the ground around the ball towards the extremities of the roots. Rhododendrons and what are generally termed American plants, bear removal so well that these where not growing satisfactorily should be taken up, the ground well prepared by a liberal addition of peat or leaf soil, and replanted. Gladiolus bulbs may now be planted; choose a warm, thoroughly drained situation, work the soil well by deep digging, and add plenty of rotten manure; elevate the bed or patch a few inches above the ground level; plant the bulbs 5 or 6 inches deep, and 6 inches apart, surrounding them with 1 inch of sand before covering them with soil; and protect during the winter against excessive wet and frost with a thick layer of sawdust, old tan, dry litter, an old carpet, thatched frames, or tarpaulin. The last three coverings must be removed during favourable weather, and the other coverings should be entirely cleared off when the plants appear. Ranunculuses may also now be planted. The situation of the beds should be cool and somewhat moist, at the same time there should be good drainage. The most suitable soil is a hazel loam. If, therefore, the natural soil be unsuitable, remove it to the depth of about 2 feet, and to the width of 4 feet, replacing it with rich loam from an old pasture; this ought to be firmly trodden in, and should form the foundation and principal portion of the bed. Next should come a liberal dressing of well-decayed manure, mixing it a little with the under soil; and over this, for the top of the bed, should be a layer of soil 6 inches deep for planting the tubers in. The soil for this purpose should be stiffish fibrous loam, mixed with well-decayed cow dung and leaf soil. Draw drills 6 inches apart and 2 inches deep, with a small hoe, and plant the roots 4 inches apart, with the claws downwards, gently pressing them into the soil. The crown of the tubers should be at least 1½ inch under the surface of the bed.

GREENHOUSE AND CONSERVATORY.

During weather like the present these structures will require very careful management. The best plan is to keep as low a temperature, and the air as dry, as can possibly be permitted—say a heat of from 40° to 45° at night, allowing it to rise a little in the day. In the mixed greenhouse let the young stock of Heliotropes, Pelargoniums, Cyclamens, and other flowers grown especially for winter, have light situations and regular attention as regards watering. The forcing-pit must provide at the proper season such plants as Rhododendrons, Azaleas, Persian Lilacs, Sweet Briars, Moss Roses, Sedums, Kalmias, Daphnes, Anne Boleyn Pinks, bulbs, &c. If the heat is furnished by fermenting materials, keep down accumulating damp and mouldiness by an almost constant ventilation, increasing the linings in order to raise the necessary temperature. Those who possess pits warmed by hot water will, of course, pursue a somewhat different course. Attend carefully to specimen hardwooded plants which it may be necessary to winter in the conservatory; most of these are impatient of fire heat and a confined atmosphere. Use no more artificial warmth, therefore, than is absolutely necessary. Take advantage of mild days to give air freely to cold pits, and keep the plants very sparingly supplied with water at the roots, so as to prevent the production of weak wood full of sap. Look frequently over anything subject to the attacks of mildew, and apply sulphur the moment this pest makes its appearance. See, also, that everything is perfectly free from insects. If there is any prospect of a scarcity of bloom in May next, a portion of the Achimenes and Gloxinias should be repotted at once and placed in gentle heat, choosing such as have been longest at rest, and a few Clerodendrons; Allamandas, a plant or two of Echites splendens, and Dipladenia crassinoda may also soon be started, but unless there are plants of these with well-ripened wood, and that have been some time at rest, there will be nothing gained by attempting to start them for some time, for in most cases it is difficult to maintain a sufficiently warm temperature to secure free growth if the plants have not been well prepared for an early start. A gentle bottom heat of about 80° or 85° will be of service by inducing healthy root action, and if this can be secured there will be little difficulty about obtaining free vigorous growth. Let Ixoras and all other hardwooded plants that have made sufficient growth be kept rather dry at the root, in order to check their growth and induce a tendency to form bloom buds, but do not let the soil in the pots become so dry as to affect the foliage. The conservatory being now gay with Chrysanthemums and other plants in flower, care must be taken in the very first place that all drip from the roof be avoided. To prevent drip, very little water must be applied in any way; give only that which is absolutely necessary at the roots. However, under these circumstances a very moderate amount of atmospheric heat must be afforded, for wherever heat is allowed there must be moisture in the atmosphere, otherwise the plants will soon show marks of debility; therefore, the proper conservatory management from the end of November until the early part of February, is to keep as low a temperature as possible consistently with the main object in view—viz., enabling plants with duly organised buds to develope their blossoms in a proper way.—W. KEANE.

DOINGS OF THE LAST WEEK.

WE have had a very busy week, but the work has been chiefly a repetition of that of the last few weeks.

In the kitchen garden Cabbages were earthed-up, Endive not required to be blanched uncovered carefully, Mushrooms in open sheds covered up more to protect them from the cold, and Cucumbers slightly smoked, and syringed next day with weak soft-soap water at from 110° to 120°—a liquid, by the way, easily made, and which no insect we have met with fancies, even thrips, the worst of all enemies to thoroughly beat, being destroyed by it when persevered with.

Bear in mind that at this season growing plants will stand less *smoking* and washing than in summer. It is different with plants at rest. One secret we must let out, as it is too good to be kept, and that is, a comparatively *low night temperature* is the great safeguard against insects of all kinds under glass. It will almost master one of the worst of all to destroy—the mealy bug. To thrive, this insect must have a high temperature; many pounds of tobacco and of sulphur, and bottles of expensive liquids, might be saved if we would only let our plants rest and recover themselves at night. A high

temperature from sun heat will rarely in these latitudes hurt a plant or a man if the first have free ventilation and the second have energy and determination to keep moving; but how can either be refreshed with a high temperature in darkness, when sleep and repose are necessary for both? Not long ago we were asked to look at Cucumbers in a house plastered with green fly, and no wonder, for the temperature at 8 P.M. was fully 80°. The temperature enervated the plants, and all the airing, &c., during the day could not make them robust. With two or three cool smokings and warm washings the insects were mastered, and the plants recovered in a night temperature of from 60° to 65°, and a day temperature of from 65° to 70°, with a gradual rise of 10° from sun heat, with little air, but that early given.

Two facts are here worth repeating. The first is, that the smoke from all combinations of tobacco cannot reach the plants too cool. Of all tobacco, shag is the safest and best. In these smoking days, however, we seldom use it, as it is always as well to keep temptation out of people's way; and hence, what little we use is confined to the paper and other preparations advertised, but in the case of all of them if the smoke reach the plant but it is sure to injure the leaves. The second fact is, that no plant ought to have its leaves damp when smoked with any preparation of tobacco. Fumigating plants when their leaves are damp, does more injury to them than to the insects. We have seen tender plants almost killed from being syringed before being smoked, although they would have been uninjured if the foliage had been dry.

Smoking, to be effectual and safe, must be resorted to when the first insects appear. Waiting until leaves become crusted or plastered with aphides is merely wasting time and tobacco. It would often be better to take all the leaves off or take the plants up. When so bad frequent smokings must be resorted to, as the smoke has no effect, we believe, on the eggs, which are quickly hatched by the heat. Soap or size water is more prejudicial to them, as shutting them up with a thin film from the air. Tobacco is often worse than wasted, because used too late.

When plants are planted out in pits, frames, and houses, unless individually they can be enclosed in a cloth, the house or pit must be smoked. In the case of plants grown in pots and moveable, it would be seldom necessary to smoke a house, and thus make it repulsive to many for a time, as one pot or a number of pots might be smoked and kept long enough in a small close box; and thus, often a pinch of tobacco or its preparations would be as serviceable as ounces or pounds in a larger place.

As against smoking we have great faith, when they can be had and applied, in nimble fingers and water-washings. The chief advantage of smoking is that the smoke penetrates into every joint and cranny. We have seen tobacco water, strong, too, used in washing shoots infested with insects, killing the insects, but often killing the shoots as well. Running the fingers and thumb along the shoots to squeeze the insects, and then washing all the remains off with a forcible jet from the syringe would be equally effective as respects the destruction of the insects, quite as pleasant to the operator, and more safe to the plant itself. Often when we went more from home we have been anxiously consulted by young ladies as to how they were to free from insects some favourite plant in a window, every unhealthy symptom making them uneasy as associated with omens as to the condition of the giver, far away, but not out of mind if out of sight. The tenth part of the time spent in merely looking and fretting would have been more than sufficient with their pliant fingers, with or without the help of a sponge, to clear away every insect and every particle of dust, and cause the renovated plant to become in very thankfulness a cheering forecaster of hopes and joys to come.

FRUIT GARDEN.

We have done little more than previously referred to. Strawberry pots out of doors are chiefly lying on their broadsides to escape the drizzling showers, and we have a little litter and straw ready to throw over them in frost. Pruning may be proceeded with, as the frost will cause the leaves to cling for some time to Apples and Pears. It is rather singular the frosts should have destroyed them when even Scarlet Pelargonium leaves and Peach leaves escaped. The leaves of the latter out of doors are still too green.

Planting may be proceeded with if the soil is damp enough. In this neighbourhood, at a few inches from the surface, it is far too dry and hard to permit of planting on a large scale being done with advantage. Nurserymen complain that they cannot take up trees and shrubs without the help of the pickaxe, and then customers grumble that the trees do not succeed well when removed from such dust-dry soil. Better under such circumstances to wait a little; or, if that cannot be done, let the roots be taken up with unusual care, be well soaked and puddled, and then packed in damp litter; and when planted the somewhat damp surface soil should be packed round the roots where watering cannot be resorted to. In general the surface soil is damp enough for 3 or 4 inches in depth, but in our case, and in this neighbourhood, wherever a crop has been grown, at a greater depth the soil is very dry, showing that much rain is wanted to give it its common amount of moisture.

ORNAMENTAL DEPARTMENT.

The same facts apply to the *removal of* all trees and shrubs in the pleasure grounds. Plants brought from a distance will require additional care on account of the dryness of the soil. Those merely moved at home can have that care supplied by attention to watering. For mere levelling, where no great depth has to be penetrated, no weather could answer better, and turfing done now will give no trouble afterwards, as the surface soil is quite damp enough. One reason why Scarlet Pelargoniums withstood the frost so well was greatly owing to the bulk of the roots being so dry. With respect to them we noticed a singular fact yesterday, when we cleared the most of them away. The weather being dry, the most of the leaves were as fresh and green as they were in August, the footstalks of the leaves were also seemingly quite sound; but though many of the stems looked green, the heart was frosted black or brown. Below the ground and a few inches above it the stems and roots were safe after passing through several frosts of 10°, and many slighter ones. These roots on an emergency, if taken up and packed closely in any place, however dark, would have broken well as the days lengthened and warmed in spring. Some of the beds, especially those of variegated Pelargoniums and Heliotropes, began to taint the air, and as the weather was dry, we cleared the whole off, making a bottom of a large rubbish-heap with the material, if we do not move it again to make the bottoms of hotbeds. In wet weather, proceeded with clearing and boxing the Pelargoniums taken up from the beds, and which have been kept safe under a little litter. We also potted, moved, and cleaned pot plants.

No weather could be better for making alterations in ground work. This is often more necessary in small places than in large ones, as the smaller the place the sooner it becomes monotonous to the eye. The smaller the place the easier it would be to change the general aspect every year. A great point would be gained, as respects pleasing variety, if every owner would study the nature of his own place, and gratify his own individual taste, and then we should not find in so many cases that one garden is so much a repetition of another. Even in the front gardens of suburban residences we should like to walk along, look through the open railings and see every little garden different in its arrangements from all the rest. A vast variety as to the arrangements of grass and gravel, plants and shrubs, could thus be seen in a single suburban street, and every owner would derive a higher gratification than in merely imitating his neighbour.

For planting Tulips and other bulbs no weather could be more suitable; much depends on having them in good condition. Had we a little garden, and could spare a little money, we should at least dip into Crocus collections. What can be more beautiful in spring, even in good patches of a colour, planting the bulbs or corms 2 or 3 inches apart? And what more interesting than contrasting these yellow, blue, white, and purple colours in artistic tracery, love-knots, &c.? Before the group beds were cleared and ready, all bulbs could be set on leaf mould, covered over, and lifted carefully when the ground is well prepared for them.

Zinc roofs.—In our corridors—glazed in front and zinc-roofed—such plants as the Coleuses, that made a fine appearance all the summer, began to show the effects of the cold, though not at all frosted, by dropping their leaves. They passed, however, the cold of Oct. 19th and thereabouts, and only suffered last week. The plants were too large for us to attempt to keep, as we have small plants which will take little room in winter. The full enjoyment of such corridors, however, depends very much on being able to keep them temperate by heating in winter, and this we hope to have done. Where only a temperate heat is required, and the mere keeping out of frost in severe weather, no mode of heating is so economical as by portable iron stoves inside the place. Where more is wanted, combined with comfort and freedom from the trouble of firing inside the

place, and the space is at all large, nothing will compare with heating by hot water. Thanks to husbanding sun heat, and the still enclosed air, our unheated corridors have kept plants better than we could have expected. Where there is a lofty glass roof and a thick wall at the back, such plants as Scarlet Pelargoniums have withstood rather severe frosts. With a lower curvilinear roof of zinc the frost made no impression on plants where the glass in front was protected by blinds; where not so protected at one end, Fuchsia leaves and Pelargoniums near the glass were crusted with frost last week. Something depends on colour, more than is generally imagined. The back wall is painted a light stone colour, which does not absorb heat quickly, but it radiates heat very slowly. Had we sunny days these walls would reflect light and heat more than they would absorb it. The top of the semicircular zinc roof inside is painted almost a pure white, which helps to make the place more light, as any rays that reach the concave roof will be reflected rather than absorbed. Zinc oxidises very slowly when exposed to the air, but still it oxidises, and to prevent it ours was painted outside as well as inside. By our suggestion it was first painted a rather light stone colour. Last time our opinion was overruled, and it was painted a dark lead colour—rather darker than the natural colour of the zinc. When of a light colour outside, the zinc-covered portion was warmer in winter than that covered with glass, partly owing to its greater closeness, as then the glazing was done with small squares. Since it has been painted of a dark colour, the zinc-covered portion is much warmer in summer and much colder in winter than that portion covered with glass. The white colouring inside does a little, but not much, to prevent the dark colour outside freely absorbing and freely radiating heat. Hence the zinc becomes very hot in a sunny day in summer, and very cold in frosty nights in winter. From the same causes, when zinc roofs are merely supported on rafters 2 or 3 feet apart, and the zinc is left of its natural colour, or painted of a dark tint, the outline of the roof, instead of being uniform, will be puckered into inequalities, marring its levelness, though not injuring it as a roof for protecting from wet.

This reminds us that a correspondent says, "I have a lot of old sheets of zinc lying about that had been used for roofing, 3 feet wide and 5 feet long, uneven but sound, with the exception of a few holes—could I use them for covering cold earth or turf pits?" Yes, if not deemed too good for the purpose. We would place each sheet on a hard level surface, level the worst of the inequalities, then pile one sheet on the other, cover them with a level surface, with heavy weights make the sheets pretty level, and then fasten each sheet to a light frame of wood. These, placed closely together, will make a good covering without rafters. In wet, mild weather they could be elevated back and front, in fine weather be lifted off; the colour would be of little consequence, as in frosty weather they could be covered with fern, litter, &c. Even the many-cornered pieces can be easily reduced into shape, for though zinc cuts badly, a pair of steel scissors, procured from an ironmonger on purpose, will clip it almost as easily as common scissors will clip calico.—R. F.

TRADE CATALOGUE RECEIVED.

J. Whitehead, Croft Bank, Hollinwood, near Manchester.—*Catalogue of Carnations, Picotees, Pinks, &c.*

COVENT GARDEN MARKET.—November 10.

Scarcely any alteration worth quoting; the attendance of buyers, however, has been better during the last few days.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Books (*A Subscriber*).—The "Garden Manual," "The Cottage Gardeners' Dictionary," and Johnson's "Science and Practice of Gardening," will give you all necessary information. You can have them post free from our office if you forward 12*s.* 2*d.* in postage stamps with your address. We cannot answer your question about the Customs.

Address (*A Subscriber*).—We do not know it.

Prolonging the Beauty of the Arbutus Berry.—"It is too valuable for purposes of table and other decoration to allow it to die without an effort to prolong its existence." Try dipping the berries, when quite dry, as they hang on the shrubs, into some coachmakers' colourless varnish.

Excrescences at the Base of Hollyhock Stems (*H. B., Honiton*).—The excrescences were caused, we think, by the stems being cut down too early. The roots were still active, and the growth not sufficiently fast to dispose of the sap they supplied, and it consequently extravasated. Probably it will not perceptibly injure the next year's blooming.

Various (*Amateur*).—We do not think there would be a sufficient demand for such a work as you name. There is no good work on aquaria. Some notes on the marine aquarium are in our columns to-day. You will have seen in our last number some directions for wintering Coleuses. Mr. Lloyd's successor is Mr. King; the direction is Great Portland Street.

Silver Beet Culture (*D. H.*).—The seed should be sown in good rich soil at the beginning of May, in drills 15 inches apart, like the common Beetroot. The plants should be thinned out, when large enough, to a foot apart in the rows. They should be kept free of weeds, stirring the ground about them until they are of good size, or as long as it can be done without injury to the leaves. The midribs of the leaves are used like Sea-kale. No blanching is required, but some cover the plants with Sea-kale pots, and the pots with leaves. In this way the midribs become more tender, but are less vigorous, though if the plants start for seed the stem is good. Some take up the roots and place them in a cellar, covering them with dry sand; and in a Mushroom or other house where there is a gentle heat, they may be blanched by covering with boxes or pots, and the leaves are very tender, more so than those taken from the plants in the open ground, but what is gained in tenderness is lost in flavour; besides, the midribs are not so thick and fleshy.

Passion-flower not Flowering (*E. B. B.*).—Your plants being seedlings, will account for their not flowering, and we advise you to thin out the shoots now so as to expose them fully to light and air, and thin them out considerably next year, so that they may continue so. Keep them dry at the roots from now until next March, or until they begin to grow, and yet not so dry as to cause the shoots to shrivel. The roots are best confined, as when these have a large space to run in the plants grow much too freely, and, of course, flower sparingly, and in some cases not at all. We should think your plants will flower next year, but it is not unusual for seedlings not to flower until the third or fourth season.

Planting Anemones (*T. H.*).—The best times to plant Anemones are October and February. We prefer October for all but very heavy wet soils, and there we think February planting best. The October planting flowers earlier than the February one. For named kinds required for furnishing blooms at a certain time, February planting may be desirable, otherwise we do not recommend keeping the roots out of the ground so long, except for the purpose of increase.

Salting Asparagus Beds (*H. J. R.*).—The present is not a good time for applying salt, because the rains and snows of winter wash it away; the roots are at rest, therefore do not absorb it, and it acts as a stimulant to their bark at a time when they are injured rather than benefited by stimulation. Two or three slight saltings of beds during the growing period are the best practice.

Ranunculuses in Pots (*P. C.*).—They are not often grown in pots, but they may be grown in that way. See answer to "*Iris*," October 7th, page 290.

Gishurst Compound (*A Caution*).—Apply it exactly according to the printed directions which accompany the compound.

Pruning a Vine in a Ground Vinery (*A Cottager*).—We have referred to "ground vinery" page 51, No. 433, and as the one rod left has grown strong, and is 7 feet in length, we would cut it back to 3 or 3½ feet. It would have helped the ripening of the wood if you had given little air after the middle of September. The sun heat is the best of all maturers.

Vines in Pots (*A Working Mechanic*).—If a heavy crop be taken from a young Vine in a pot, it will rarely do any good the second year, as all its energies were exhausted in the crop. If only three or four bunches were taken and the wood were strong, the plant might do tolerably well in the following season, if—say, in a 15-inch pot; but if the plant is in a pot of that size now, it will often be better to richly top-dress instead of fresh potting so late. Everything fruited in a pot does best when, before starting into fresh growth, the pot is full of roots.

Watering an Inside Vine Border (*Cliftoniensis*).—We would water the border inside directly, making some holes and doing it at two operations instead of once, allowing an interval of a week or ten days between them. If the soil is so dry to the depth of 2 feet, the roots are apt to be dried-up, and, what is worse, to go down deeper in search of moisture. There could be no reason for keeping the roots so dry after the fruit was cut in August, unless it was to help to ripen the wood, but this dryness may easily be carried to excess. We would use tepid water.

Oxalis tropæoloides (*H. M.*).—As you have no greenhouse or other convenience, we would advise you to let your thick patch of Oxalis tropæoloides remain where it is; merely put some dry ashes over and among it, and stick round and over it some evergreen twigs. The plants will most likely lose their tops, but they will come up strongly next spring. Last season, with us north of London, it was perfectly hardy. We merely took it up and transplanted it regularly. We will serve it, Cineraria maritima, and Centaurea candidissima as above, with dry ashes and burnt earth.

Sewage (*H.*).—The residuum is very little and not offensive, the constant passage of fluid dissolves everything but paper.

Compost for Roses (*F. H. G.*).—The mixture of horse dung and malt dust recommended by Mr. Rivers, may be used fresh, but will preserve its efficiency for a long time if kept under cover.

Furnace for Steam-heating (*E. C. Hedges*).—For a hothouse to be heated by steam-pipes, we should prefer the furnace to be outside the house, as thus some possible inconveniences could be avoided. Furnaces inside hothouses are only advisable when the utmost economy as respects fuel is to be considered.

Heating a Small Greenhouse (*Forest Hill*).—The cheapest mode of heating your house, 16 feet by 5, is by a small iron stove with a flat top, so that you can place a pan of water on the top, and take a 3 or 4-inch pipe through the roof or back of the house. If your stove fireplace is lined with firebrick all the better. One costing about 50*s.* should suit your purpose. We presume you have read something of what has been said of the management of such stoves. We are in doubt about the Ferns unless they are rather hardy kinds, and even they should not come very near the stove. The Camellias and Azaleas will be quite safe at 35°, but to bloom well they require from 45° to 50°.

Heating a Fernery and Greenhouse from one Boiler (*E. L. I.*).—Is the fernery now insufficiently heated from the boiler, owing to the pipes being so few? If so, then the cheapest and simplest mode would be to connect the old and new pipes, especially the flow, and the simplest mode of doing this would be to connect them with 1-inch gas pipes, with a screw into each pipe. If the new pipe is on the same plane as the old pipe it will soon be nearly as hot. We have no doubt that from Weeks's tubular boiler you can heat your greenhouse and fernery equally well, though the latter is 3 feet below the level of the former, provided, as shown by your sketch, the lowest pipes in the fernery are above the level of the top of the boiler, and more especially as you seem to take two separate flows from the boiler—one flow to the greenhouse, and one flow to the fernery. Each pipe is, therefore, independent of the other. It is often different when different places on different levels are heated from one flow-pipe, branch off as it may, as then there will always be a tendency to have the greatest flow to the highest point. Hence, in heating warehouses, &c., in two or three storeys, it is often best—generally best—to take the flow to a cistern at the highest point, and from thence take flows downward from the higher to the lower storey. The heat is thus more equalised than if taken into the lower storey at once from the ascending flow-pipe; and so when a number of houses and pits are to be heated, the flows being of different levels. You will avoid this by the separate flow for each house direct from the boiler. We do not see why on account of a wall, you should bend down your pipe as it leaves the boiler for the fernery. This lowering of the pipe is always injudicious. To make it answer you would require an open air-pipe at the bend. Even then we should not like it. If really the level of the pipes in the fernery requires this, then the simplest remedy against all likely mishaps would be to sink the boiler. There will never be rapid circulation, if so soon after issuing from the boiler, the pipe sinks so much. Your success will depend on an open cistern at the farther end, and a small, open, gas air-pipe over the bend. The working will always be best when every heating-pipe is above the level of the top of the boiler. The returns may be thus situated before it is necessary to dip down to the bottom of the boiler.

Cucumber Winter Culture in Pots (*Choque*).—There is no difficulty in growing Cucumbers in pots in a stove, the chief point is to secure an average night temperature of 65°, and a day temperature of from 70° to 75°, and of 80° with sun heat. Any part of the stove will do, provided the leaves of the plant be exposed to all the sun and light possible. We have had the pots on the curbe of a pit above a flue, plunged partly in a bed, and sometimes set on a shelf at the back of the house, and the vines of the plant trained down. If anything, the plants did rather the best when the pots were set in a bed, so as to have an average heat of 80°, not more, at the roots. When we wanted Cucumbers quickly, we have grown them in 8-inch pots. Fifteen inches is a very good average size. The soil for winter may be two parts of sweet fibrous sandy loam, and one part of equal quantities of heath soil, dried sweet leaf mould, and a little charcoal. The heath soil helps now; after January we would rather be without it.

Eschscholtzias (*Sacrotivir*).—They are herbaceous plants. In Paxton's Dictionary they are erroneously called tuberous-rooted, and in the "Cottage Gardeners' Dictionary" as erroneously bulbous-rooted. The genus Venidium is Arctotis, and Callirhoe is Nuttalia in the "Cottage Gardeners' Dictionary." Centauridium Drummondi is a recent introduction.

Packing Trees for Exportation (*Subscriber*).—Tie the branches of each together, envelope the roots in moss, and wind a straw band round the whole—roots, stem, and branches; and after tying the trees together in a bundle, envelope it with straw as you see done by nurserymen. Now is a good time to send them.

Eradicating Horseradish (*Oakham*).—We know of no better plan than persisting in what you have done. To dig up the plants by the roots is labour in vain, as it is next to impossible to find every piece, and not unfrequently, from the pieces left, it is a source of increase rather than clearance, and we are not surprised that you trenching the ground has caused it to come up more thickly than ever. Continue to pull up the plants as they appear, not waiting until they have grown to a considerable extent; but as soon as they can be laid hold of remove the soil about each a few inches deep, or so that they can be laid hold of, and pull them up, placing a little salt in the hole from which the roots were drawn.

Cutting Down an Oleander (*Idem*).—Cut it down at the end of March, keeping it rather dry, or avoid making the soil very wet until it begins to grow, and has shoots a few inches long, then repot, keeping a moist atmosphere, and do not water heavily at the roots until they are working freely in the fresh soil, then water freely. In repotting remove as much of the old soil as can be done, reducing the ball considerably, and pot in a smaller-sized pot.

Potting Hyacinths to Bloom in March (*A Subscriber*).—Hyacinths, Tulips, Narcissuses, and Crocuses to flower at the end of February and through March, ought to be potted without delay; indeed, they would have been better potted a month sooner. Place them in a cold frame, and cover them with spent tan or ashes to about an inch over the rims of the pots; only employ the lights to keep off heavy rains and during severe weather. About Christmas remove the bulbs to a cool house, placing them in the most light and airy position, and as near the glass as practicable. Up to February the temperature from fire heat should not exceed 40°, when it may be increased to 45°, and in that they will bloom at the time required.

Pruning Roses (*A. D.*).—You may now peg the shoots down, or cut them back to within three or four eyes of where you would prune them to, deferring the final pruning until the beginning of March, or if you peg the shoots down you could draw out the pegs in March, and then prune the plants as required, or leave them to flower as they were pegged, merely removing the points of the shoots. By the partial pruning now, or pegging down the shoots, you would escape the winds, and by deferring the pruning until March, injury from spring frosts would be avoided. Your question was answered October, 21st, page 328.

Red Spider (*Idem*).—You do not say what are the occupants of your house, and we cannot, therefore, advise.

Newtown Pippin in an Orchard House (*Idem*).—Like Pears, Apples do not mature well in an orchard house; but placed out of doors in August they mature perfectly. It is, perhaps, due to the greater dryness of the atmosphere of an orchard house, as compared with the open air, and the want of dew in the former.—G. A.

Climbers for a Greenhouse (*A. B.*).—There are no plants which will endure the gas. Why not have a funnel or funnels connected with the exterior to take away the fumes of the gas? Habrothamnus elegans, Hoya carnosa, Hibbertia volubilis, Jasminum gracile, Kennedya inophylla floribunda, K. monophylla, K. Marryattæ, K. rubicunda superba; Lapageria rosea, Plumbago capensis, Rhynchospermum jasminoides, Sollya linearis, Tacsonia Van-Volxemi, and Tropæolum Triomphe de Gand.

Bulbs after Flowering (*Poor Amateur*).—There is no necessity for throwing the bulbs on the rubbish heap after they have been forced; but they flower so indifferently a second year in pots that for the most part they are not employed, but planted out in the borders, where they do well. After flowering continue the bulbs in a light airy position, and in a house from which frost is excluded, supplying them with water as required; and when danger from frost is past plant them out in the open ground, supplying them with water until the leaves turn yellow; then withhold it, and when quite yellow take up the bulbs, dry them, and remove the loose skin and offsets, keeping the bulbs in a dry place until planting time.

Australian Seeds (*Centurion*).—Albizzia lophantha is a synonyme of Acacia lophantha. Alyxias are Apocynaceous plants, all described in Don's "Botanical Dictionary." A. pugioniformis is a variety of A. ruscifolia, pictured in Loddiges' "Botanical Cabinet." Banera is in the "Cottage Gardeners' Dictionary." B. rubioides and rubiæfolia are the same. Cryptocarya glaucescens is a Lauraceous shrub, noticed in Loudon's "Hortus Britannicus." Fremela empressiformis is a Cogniet, described in the last edition of Loudon's "Encyclopædia of Plants." Sow in February or March; directions are given in our vol. xv., page 424.

Humea elegans (*S. P.*).—The plants which have flowered this year will not do so next. Those which have not flowered should be taken up and potted; winter them in a cool airy house, repotting them as the pots become filled with roots, and they will flower well next year. It will be sufficient if frost be excluded from the house in which they are wintered. Humea elegans is a biennial, but flowers the first year if sown early; to do well the seed ought to be sown in May, and the plants treated as biennials.

Erratum.—Page 362, left-hand column, twenty-seventh line, for "white at top and black at bottom," read "*black at top and white at bottom.*"

Apples, &c. (*A Novice*).—Absence was the cause of their not being named, and when we returned they were too decayed to be recognised. Send some other specimens.

Names of Fruits (*E. W.*).—Beauty of Kent. (*New Forest*).—Beurré Bosc and Beurré d'Aremberg quite correct. The former is sometimes coarse in the flesh, and decays at the core. (*F. L. A.*).—1, Thompson's; 2, Achan; 3, Chaumontel; 4, Beurré Nantais; 5, Borovitski; 6, Nonpareil; 7, Lewis's Incomparable.

Names of Plants (*J. L. D.*).—We cannot name plants from their leaves only. (*M. H.*).—1, Aster Novi-Belgii; 2, A. Novæ-Angliæ; 3, A. tardiflorus, var. cæspitosus; 4, A. cyaneus. (*James Scott*).—1, Peristrophe speciosa, formerly known as Justicia speciosa; 2, Aster Novi-Belgii. (*Ballybrophy*).—Lonicera involucrata. This may be thought a very curious Honeysuckle, and is, indeed, a great departure from the ordinary character of the genus. It is native of California. (*D. M.*).—We take your plant to be Lobelia ilicifolia; unfortunately our material is not the best, there not being a perfect flower on your specimen.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending November 9th.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE CARPET KNIGHTS AND LA DAME DES POULES.

Your correspondent, signing himself "Justice," will be quite able to rejoin to "Aliquis;" but at the risk of being thought meddlesome, I must say a few words on "Our Poultry Shows," moved by the desire to resist anything which may try to retard the reforms proposed.

The carpet knights, mentioned by "Aliquis" as gentlemen "who leave their drawing-rooms to blister their fingers with boxes and hampers, and pens, and cages, and rope, and string, and canvas, and packing-needles," can do all that "Aliquis" sets forth; and, in the spirit of that chivalry which "Aliquis" invokes, will do so without needing the reward of successful competition or a prize of money's worth. The lady writing out the "copy" of a heavy catalogue, folding and addressing the early editions so that they may reach the breakfast-tables of anxious exhibitors, plying her packing-needle, &c., deserves the praise which she appears to have won from "rough and honest men;" but she would be no less a lady, nor a less fitting companion picture to the carpet knights, if she declined to compete for honours in her own neighbourhood. The sum and substance of these word pictures, divested of the haze of "all that is chivalrous," amounts to this—namely, that committeemen who "dip their hands deeply into their pockets," and incur "labour and expense," should receive, or have the chance of receiving, a *quid pro quo*.

The first objection, urged by "Justice" and endorsed by myself, is, therefore, not answered; it is simply re-asserted in a cloud of words. The attempted answer to the second objection I do not understand, in consequence of some confusion in the pronouns used by "Aliquis." The case, however, which he puts is admitted by him to be one which "is not contemplated, and will not often occur;" and which, if of "frequent repetition, would defeat its original intention." If so, where is the use in supposing anything of the kind?

I am happy to see that the Birmingham authorities are setting a good example in discouraging competition on the part of committeemen and others officially connected with poultry shows.—Egomet.

LONDON POULTRY SHOW.

There will be a London Poultry Show at the commencement of next year. A prize list of £300 will be guaranteed by the Committee and the Directors of the Crystal Palace, where the Exhibition will be held.

AUCTION AT THE BIRMINGHAM POULTRY EXHIBITION.

There is one point which your correspondents who desire an alteration in the time of the auction at the Birmingham Show appear to have overlooked—namely, that some fanciers have made their arrangements already to attend on the Monday, and cannot well change the day. I certainly think it would be scarcely fair if the Committee were now to defer the sale until Tuesday. They might fix a later hour, say three or four o'clock in the afternoon, and thereby meet what appears to be a real want; but the change to another day ought not, in my opinion, to be made this year after the public have been all along led to believe that the sale would take place on the Monday. At the same time I fully coincide in what your correspondents have urged, that it is very advisable so to arrange matters that there may be no occasion for any one to be away from home or to travel on the Lord's day.—E. M. B. A.

THE BIRMINGHAM POULTRY SHOW.

The entries closed on the 1st inst., and are such as to warrant the conclusion that the Show will be of the usual popular and interesting character. Fluctuations there must inevitably be; but from the subjoined statement it will be seen that, although in some instances there is a decrease, as compared with 1868, the aggregate exceeds the average of several preceding years. Although an additional charge of 6*d.* per pen is made to exhibitors of poultry, with the view to check the constantly increasing demands for space, the feathered races will still be fully represented.

	1865.	1866.	1867.	1868.	1869.
Poultry	1675	1897	2111	2315	2016
Pigeons	331	418	565	432	490

LISTS OF PRIZES.

Persons sending birds to a distance may not be able to attend the exhibition themselves, but will naturally be very anxious to learn the decision of the judges; they, therefore, send the amount required for a list of awards, requesting and hoping the Secretary will send it to them by post the evening of the first day of the show; instead of doing so, a list is received, perhaps, after the birds have arrived at home; at any rate after it is of no use, as the result has then been published in the daily papers. Secretaries ought to post the list on the evening of the first day of the Show, and I think exhibitors are entitled to this little attention.—Aliquis.

MISTAKES AT THE CHESTER SHOW.

I have received a pen of Dark Brahmas, which I presume has been sent to me in error from Chester Show. Attached to the basket in which they came is an exhibition label No. 139, on the back of which is my name and address in full. You will oblige by giving the above facts publicity, as I am anxious to return the birds to their rightful owner, who may in the meantime rest assured that his birds are well cared for.

In connection with the above Show, I with many other exhibitors would like to have explained why we were all (whether exhibitors of poultry, Pigeons, or dogs), charged 6*d.* per basket for its conveyance from the Show to the railway station. As there were 843 entries, and presuming there were 700 returned by rail, the exhibitors were charged £17 10*s.* for what at other shows is generally done gratis.—Richard M. Lord, *Penn Road, Wolverhampton.*

BRISTOL AND CLIFTON POULTRY AND PIGEON SHOW.

In many respects the Bristol and Clifton Show has been remarkable; but chiefly for the fact, that although conducted for two successive seasons at a heavy pecuniary loss sufficient to dishearten most men, the indomitable "pluck" of the Committee, who on the third occasion issued a schedule which in the face of the past might almost be termed audacious, not only fairly turned the scale as regards pecuniary matters, but actually placed the Show next to Birmingham, beating even Manchester in the number of poultry entries. The new sche-

dule is now before us, and we must say that a more extraordinary sheet was never issued. Thirty silver cups, amounting in value to not far short of £200, and money prizes over £330, are the grand totals, and grand they are. Even Birmingham will need to be on the alert if this western upstart is to be "kept behind." There will be an increased number of judges this year; and with a hall unsurpassed anywhere for purposes of exhibition, no doubt the show will be even more than last year a triumphant success. We note as a hint to other committees that there is an excellent trimming clause, stating that the judges' attention will be specially requested to any fraudulent proceedings, but leaving the responsibility with them. This is right.

PRIZES FOR FRENCH VARIETIES OF FOWLS.

I also applied for three out of the four prize lists mentioned by "Blackbird," and not caring to enter my Crève-Cœurs in the "Any other variety classes," I have not entered them at either show. I last spring gave a long price for the first-prize Crève-Cœurs at Hull, and though they there beat a very good class, and at Ipswich the cock was called by *The Field* a very first-rate bird, at Beverley, in the "Variety class," they were only highly commended, as were two other pens of Crève-Cœurs, the prizes going to Sultans and Black Hamburghs. I do not at all dispute the decision of the judge, as the prize pens were as good of their kind as they could be, I only wish to prove that the Frenchmen should have a class to themselves, as they do not stand a chance against Sultans in the show-yard, and not much against Black Hamburghs, though at most shows French fowls outnumber the other sorts by three or four to one. I am this week sending birds three hundred miles to a show, as I cannot hear of a French class near home; and I am sure that if breeders of French fowls only show where they have a class for their favourites, they will soon find that they will not have to waste so many stamps as they have to do now in finding a prize list with a class for French fowls.—Crève-Cœur.

[We have heard from more than one committee that if the breeders of French fowls will agree to send a certain number of pens, or to offer a cup as a prize to be competed for by them, the committees would have a class or classes for the said fowls.]

CHESTER POULTRY SHOW.

At the recent poultry Show held at Chester I entered a pen of fowls, and, as usual, on forwarding them paid the carriage, 1*s.* 10*d.* To my surprise, on receiving them back, I was charged 2*s.* 6*d.* At first I thought I had received the wrong birds again, that probably they had been so well provided for during their absence from home as to have increased in weight: but no, neither supposition was true. I then inquired from the other exhibitors here, and I find they, too, have been dealt with in the same way. Now, as I am determined to find out how this occurs, and if possible put a stop to so gross an imposition, I should like to ask your readers, if any, who may have experienced the same imposition, if they can give me any information, as it is my intention to obtain a repayment of the overcharge if possible.—Henry Vaughan.

LICE ON PIGEONS.

I find nine out of ten Pigeon fanciers who give very high prices for birds, know very little about their treatment. I am constantly receiving letters from gentlemen about their Pigeons dying from some cause unknown to them. To keep a flight of fancy Pigeons in health and prosperity, they require as much care and attention as that which a good shepherd bestows on his flock.

Pigeons are all more or less troubled with two different sorts of vermin, called "Pigeon lice." I can always tell when one of my birds is troubled with these pests. Birds so affected may easily be found out; they will while walking about suddenly stop and peck very quickly under their wing, and other parts of their body, and shake their feet as if wanting to get rid of something disagreeable. My treatment is to dress my birds twice every year with sheep ointment, or blue unction, in the following manner:—I take a small pot of ointment, and place it in a basin of warm water to melt it; then I take a small piece of stick, cutting the end flat, dip it into the ointment, and put a small quantity just above and below the vent, under each wing, and under the throat or neck of the Pigeon. By the above treatment I keep my birds free from the vermin, and they live to the age of ten or twelve years, and breed well with me up to that age.—W. Woodhouse.

CHESTER POULTRY SHOW.

The Drill Hall, Chester, though not a building of limited size, was filled almost to excess on the 4th and 5th inst. with birds from the principal poultry yards in the kingdom, consequently the Show proved unusually good. So great was the interest excited by a liberal prize schedule, that the Committee, though reluctantly, were compelled to decline more than a hundred of the entries that were last proffered to the Secretary, a very strong proof that the emulation of poultry-breeders is not subsiding. We regretted to find, as usual, that a considerable number of excellent pens arrived about the time the Judges had finished their duties.

Dorkings were the first class on the list, and very rarely have such good classes met the eyes of breeders of this useful variety of fowls. Of *Spanish* the entries were numerous, and the birds were shown in capital condition. We noticed, as everyone present must have done, a cock of this variety disqualified for having his comb tied upright with a piece of thick string, as awkwardly carried out a piece of deception as we have witnessed for many years past, for, as a gentleman jocosely remarked, "he looked as though he had a halter on." The *Game* classes were beyond question among the gems of the Chester Show, the Brown Reds being the best of those exhibited this season. *Dark Brahmas* were excellent, but we regretted to find on close inspection several pens of birds naturally falcon-hocked, very cleverly pulled some three or four weeks back, so that the half-grown feathers might insure security from detection. The Judges, however, quickly discovered the deceit, and these pens were therefore passed unnoticed. The *Cochins* were good, whether Buff, Partridge, or White. In the *Hamburgh* classes every variety was well shown, being, as a general rule, remarkably true to feather. There was a very unusual case of disease, elephantiasis in the legs of a Golden-pencilled Hamburgh cock, that drew special attention, as although hitherto almost unknown among any variety of fowls save Cochins, of late several cases have presented themselves among Sebright Bantams and Crève-Cœurs. It is a disease that should be promptly dealt with in its early stages, as it is very contagious, and when once confirmed is most difficult to eradicate. The Pencilled cock just alluded to had legs increased in size by this disease, until they were almost as large as those of a Dorking. Compound sulphur ointment in the early stages is an excellent application. *Polish* were better by far than customary, and the entry was a large one. Game *Bantams* were not exhibited in the condition they should have been. Thirty-six pens in the "Selling class" formed a very good entry, and were so good that many lots changed hands, the maximum price being 30*s.* the pen. The Aylesbury *Ducks* exhibited by Mrs. Seamons, of Aylesbury, ensured an unusual amount of interest in this neighbourhood, and Mr. Gamon's several pens of Rouen Ducks were well worthy of their position. *Geese* and *Turkeys* were especially good. In the first-named class, a pair of those rare birds, the Australian Cereopsis Geese, sent in at the very low price of five guineas, gave any intending purchaser such an opportunity of buying as might not again occur for many years; nothing in the Show could have been exhibited in finer plumage.

Pigeons had a room allotted to themselves up-stairs, and it appears not a few visitors, by oversight, were deprived of the pleasure of inspecting an unusually fine collection.

Dorkings.—1, H. Crossley. 2, J. White (Grey). *hc*, Mrs. Arkwright (Coloured); Rev. E. Bartrum, Great Berkhampstead (Coloured); Viscount Turnour, Shillinglee Park (Coloured). *c*, Rev. E. Bartrum (Coloured); T. E. Kell; N. G. Russell (Coloured); E. Shaw (Grey).

Spanish (Black).—1, H. Lane. 2, H. Beldon, Goitstock, Bingley. *hc*, T. & E. Comber, Warrington; R. Davies; F. James; P. H. Jones, Fulham. *c*, W. R. Bull; J. Gliddon; J. Siddorn.

Game Cock (Any colour).—Cup, J. Wood (Brown Red). *hc*, J. Platt (Brown Red); G. F. Ward (Brown Red). *c*, C. Chaloner, Whitwell, Chesterfield (Duckwing); J. Platt (Brown Red).

Game (Black-breasted Red).—1, C. Chaloner. 2, J. Forsyth.

Game (Brown-breasted Red).—1, J. Wood. 2 and *hc*, J. Platt. *c*, T. Burgess, Burleydam.

Game (Any other variety).—1, J. Halsall, Ince (Duckwing). 2, W. Gamon, Chester (Duckwing). *c*, W. Gamon (Duckwing); J. Halsall (Duckwing).

Game Pullet.—1 and 2, J. Wood (Brown Red). 3, J. Forsyth (Black Red). *hc*, Barker & Charnock (Black Reds); T. Burgess; T. Mason; E. Noble (Black Red).

Brahma Pootra.—1, F. O. C. Haworth. 2, H. Lingwood, Martlesham (Dark). 3, Hon. M. A. Baillie Hamilton (Dark). *hc*, Rev. E. Alder; Rev. J. Bowen (Dark); W. R. Boyle (Dark); Dr. Holmes (Dark); G. A. Stephens (Dark); Miss A. Williamson (Light); Mrs. Woodcock (Dark). *c*, Rev. J. Bowen (Dark); T. A. Dean (Light); W. B. Etches (Dark); E. Leech, Rochdale; M. Leno, Markyate street, near Dunstable; W. Gamon.

Cochin-China (Cinnamon or Buff).—1, Bowman & Fearon, Whitehaven (Buff). 2, W. A. Taylor (Buff). *hc*, W. Sanday (Buff); C. Sidgwick, Ryddlesden Hall, Keighley (Buff).

Cochin-China (Any other variety).—1, W. A. Taylor (Partridge). 2, E. Tindman, Whitehurch, Salop (Partridge). *hc*, Bowman and Fearon (White); C. Sidgwick (Partridge); Miss Story (Partridge). *c*, H. Crossley.

Polish (Black).—1 and *hc*, W. Gamon. 2, J. Dickenson.

Polish (Any other variety).—1, H. Beldon. 2 and *hc*, W. Gamon (Silver and Golden).

Hamburgh (Golden-spangled).—1, J. Ogden. 2, W. A. Hyde. *hc*, E. Brierley; Duke of Sutherland. *c*, S. & R. Ashton, Mottram.

HAMBURGHS (Silver-spangled).—1, H. Belden. 2, J. H. Howe. *hc*, Ashton & Booth. *c*, A. Woods.

HAMBURGHS (Golden-pencilled).—1, H. Belden. 2, W. R. Park. *hc*, W. Clayton; W. Speakman; Duke of Sutherland. *c*, W. Parr, Patricroft.

HAMBURGHS (Silver-pencilled).—1, Duke of Sutherland. 2 and *c*, H. Belden. *hc*, W. R. Park.

GAME BANTAM COCK.—1, J. Crosland, jun. (Black Red). 2, H. F. Nicholson (Duckwing). *hc*, W. F. Entwisle (Black Red); G. Maples (Duckwing); F. Steel (Black Red).

GAME BANTAMS.—1, W. F. Entwisle (Black Red). 2, G. Maples (Duckwing). *hc*, W. Adams; R. N. Barlow (Black Red); J. Crosland, jun. (Black Red); J. W. Oates (Black Red).

GAME BANTAMS (Any variety not Game).—1 and 2, M. Lene (Laced). *hc*, H. Belden (Black); T. C. Harrison (Laced); G. F. Hodson (Gold-laced); W. H. Tomlinson (Black); J. White (Black). *c*, Mrs. Bellyse (Gold-laced).

ANY OTHER VARIETY NOT PREVIOUSLY MENTIONED.—1, Mason & Walker (Black Hamburghs). 2, Hon. C. W. Fitzwilliam (Crève-Cœur). *hc*, S. Butterfield (Black Hamburghs); Hon. C. W. Fitzwilliam (La Flèche and Crève-Cœur); Mrs. Seamons (Crève-Cœur); Rev. W. Sergeantson (Black Hamburghs); G. A. Stephens (Houdans). *c*, J. H. Dawes (Houdans).

SELLING CLASS.—1, Rev. W. Sergeantson, Acton Burnell (Black Hamburghs). 2, Miss E. Williams (Crève-Cœur). 3, C. W. Brierley. *hc*, A. Bamford; W. F. Checkley (Buff Cochins); R. Davies (Black Spanish); W. Little (Brahma Pootra); E. Ryder (Rouen Ducks); T. Wakefield (Silver-spangled Polands). *c*, T. & E. Comber; W. J. Cope (Dockwing Game); J. Mansell (Black Spanish); H. B. Morrell (Dark Brahma); Viscount Turnour (Coloured Dorkings); C. Williams (Black Red Game).

DUCKLINGS (Aylesbury).—1 and 2, Mrs. Seamons, Aylesbury. 3, S. H. Stott. *hc*, W. Stonehouse.

DUCKLINGS (Rouen).—1, and 2, W. Gamon. 3, J. Dickenson. *hc*, W. Gamon; S. H. Stott; T. Wakefield. *c*, W. Evans.

DUCKS (Any other variety).—1, C. W. Brierley. 2 and *c*, M. Lene (Mandarin and Carolina). *hc*, S. & R. Ashton (Carolina); R. P. Williams (Bahama).

GOSLINGS.—1, S. H. Stott. 2, Mrs. Seamons. *hc*, E. Leech; R. P. Williams. *c*, G. Bagnall; Rev. G. Hustler; J. White.

TURKEYS.—1, W. Sandy, Cambridge. 2, T. & E. Comber, (Cambridge). *hc*, Earl Grosvenor (Norfolk); S. H. Stott (Cambridge).

PIGEONS.

CARRIER.—*Cock.*—1, G. C. Holt. 2, J. Hawley. *vhc*, E. Horner, Harewood. Whole class *hc*. *Hen.*—1 and *vhc*, G. C. Holt. 2, J. Hawley. *hc*, J. Thompson; E. Walker. *c*, G. H. Roberts; J. Thompson.

POUTER.—*Cock.*—1, W. Gamon. 2, E. Horner. *hc*, W. Harvey, Sheffield; J. Hawley. *Hen.*—1 and 2, E. Horner. *hc*, W. Harvey. *c*, W. Gamon.

TUMBLERS (Almond).—1, J. Fielding, jun. 2, J. H. Ivimy.

TUMBLERS (Balds or Beards).—1 and *c*, W. Woodhouse. 2, J. Fielding, jun. *hc*, F. Graham; W. Woodhouse.

TUMBLERS (Any other variety).—1, R. Minnitt, jun. (Mottles). 2, J. Fielding, jun. *hc*, J. Grice (Red). *c*, J. Hawley (Mottles).

TUMBLERS (Any variety not Short-faced).—1, J. Hawley (Mottles). 2, E. Horner.

DRAGOONS.—1, J. H. Frean. 2, Mrs. Arkwright.

BARBS.—1, J. Fielding, jun. 2, G. H. Roberts.

NUNS.—1 and 2, W. Croft. *hc*, W. Bankes; F. E. Thompson. *c*, P. H. Jones.

FANTAILS.—1, W. Harvey. 2, F. Graham. *hc*, F. Graham; E. Horner; W. B. Tomlinson; J. Walker.

JACOBINS.—1, E. Horner. 2, P. H. Jones. Extra 2, E. E. M. Royds. *hc*, R. Fleming; E. E. M. Royds.

TRUMPETERS.—1, W. Gamon. 2, W. Harvey. *hc*, W. Gamon; E. Horner. *c*, C. F. Staunton.

OWLS (Foreign).—1 and *c*, F. Graham. 2, J. Fielding, jun. *hc*, A. A. Vander Meersch.

OWLS (English).—1, J. Crosland, jun. 2, F. Graham.

TURBITS.—1, W. Bankes. 2, E. Horner. *hc*, J. Fielding, jun.; P. H. Jones.

RUNTS.—1 and 2, F. Graham.

ANTWERPS.—1, W. Harvey. 2, J. Crosland, jun. *c*, Mrs. Arkwright; W. H. Mitchell.

ANY OTHER VARIETY.—1, W. Harvey. 2, J. Fielding, jun. 3 and 4, F. Graham (New variety). *hc*, W. Harvey; E. Horner; P. H. Jones.

The Judges of *Poultry* were Messrs. Hindson, of Liverpool, and Hewitt, of Birmingham; and for *Pigeons*, Messrs. Esquilant and Hedley, both of London, officiated.

SOUTHAMPTON ORNITHOLOGICAL SHOW.

THIS was held at the Carlton Hall, Southampton, on the 9th and 10th inst., and continues this day. The following is the list of the awards:—

SPANISH.—1, F. James, Peckham Rye. 2, J. R. Rodbard, Aldwick Court, Wrington, Bristol.

DORKINGS.—1, T. Martin, Claines, Worcester. 2, J. Smith, Shillinglee, Petworth. *Chickens.*—1, O. E. Cresswell, Hanworth Rectory, Hounslow. 2, H. R. Seymour, Crowood, Hungerford.

COCHINS (Any variety).—1 and Cup for best pen, J. Cattell, Birmingham (Buff). 2, Mrs. Allsopp, Worcester.

BRAHMAS (Dark).—1, H. Lingwood, Creeting, Needham Market. 2, H. Dowsett, Pleshy, Chelmsford.

BRAHMAS (Light).—1, J. Pares, Postford, Guildford. 2, H. M. Maynard, Ryde, Isle of Wight. *Chickens.*—1, Mrs. A. Williamson, Leicester. 2, Mrs. T. Turner, Avon, Ringwood. 3, H. M. Maynard.

GAME (Black and other Reds).—1, Capt. G. Price, Taynton, Gloucester. 2, J. Fletcher, Stoneclough, Manchester. *Chickens*—1 and 2, J. Fletcher.

GAME (other variety).—1, G. Sainsbury, Devizes. 2, J. Mason, Worcester.

HAMBURGH (Silver and Gold-pencilled).—1, N. Barter, Plymouth. 2, Mrs. Allsopp. *Chickens.*—1, H. Pickles, jun., Earby, Skipton. 2, Mrs. Pattison, Dorchester.

POLANDS.—1, J. S. Watson, Earby, Skipton. 2, T. P. Edwards.

FRENCH VARIETIES.—1, Mrs. Pattison. 2, Capt. T. S. Robin, Fontenay, Jersey (Crève-Cœur).

HOUDAN CHICKENS.—1 and 2, W. O. Qnibell, Newark. 3, Hill & Co.

ANY OTHER VARIETY.—1, Hill & Co. (Gangesian). 2, J. Hinton, Warminster (Malay).

GAME BANTAMS.—1, S. Samways, Southampton. 2, E. Payne, Cardiff.

BANTAMS (Any other variety).—1, Miss A. Hodson, North Petherton. 2, H. Draycott, Humberston.

DUCKS (Aylesbury).—1, W. Tippler, Chelmsford. 2, A. Saunders, Southampton.

DUCKS (Any other variety).—1, A. Saunders (Rouen). 2, C. N. Baker, Chelsea (Mandarin).

GEESE.—1, Mrs. M. Ford, Weymouth (Toulouse). 2, Major-Gen. H. P. de Bathe, Chichester (Sebastopol).

TURKEYS.—1, St. J. Coventry, Winborne (American). 2, W. Fookes, Blandford.

SELLING CLASS.—*Cock or Cockerel.*—1, Mrs. Christie Glyndebourne, Lewes (Partridge Cochin). 2, Viscount Turnour, Petworth (Dorkings). *Hens or Pullets.*—1, W. Stanford, jun., Steyning (Dorkings). 2, T. Rogers.

PIGEONS.

POUTERS.—1, R. Fulton, Deptford. 2, H. Yardley, Birmingham.

TUMBLERS.—1 and 2, R. Fulton.

BARBS.—1 and 2, R. Fulton.

JACOBINS.—1, H. M. Maynard, Ryde. 2, J. C. Ord, Pimlico.

FANTAILS.—1 and 2, H. Yardley.

OWLS.—1, P. H. Jones, Fulham. 2, R. Fulton.

TURBITS.—1, O. E. Cresswell. 2, P. H. Jones.

CARRIERS.—1, H. M. Maynard. 2, J. C. Ord.

TRUMPETERS.—1, J. Hawley, Bingley. 2, C. Bulpin, Bridgewater.

NUNS.—1, H. Yardley. 2, C. Bulpin.

DRAGOONS.—1, H. M. Maynard. 2, J. C. Ord.

ANY OTHER DISTINCT VARIETY.—1, W. B. Tegetmeier, Finchley (Pigmy Pouters). 2, H. Yardley.

SELLING CLASS.—1, J. C. Ord (Carriers). 2, H. M. Maynard (Carriers).

CANARIES.

NORWICH (Clear Yellow).—1, T. Mann, Camberwell. 2, Messrs. Moore and Wynn, Northampton. 3, Messrs. Bemrose & Orme, Derby.

NORWICH (Clear Buff).—1, W. Walter, Winchester. 2 and 3, Messrs. Bemrose & Orme.

NORWICH (Marked or Variegated Yellow).—1, W. Walter. 2, Messrs. Moore & Wynn.

NORWICH (Marked or Variegated Buff).—1, Messrs. Moore & Wynn. 2, H. Apted, Broadwater. 3, O. Nicholson, Landport.

NORWICH (Any other variety).—1, W. Walter. 2, Messrs. Irons & Gayton, Stockley.

BELGIAN (Clear Yellow).—1, R. Richardson, Landport. 2, O. Nicholson.

BELGIAN (Clear Buff).—1, O. Nicholson. 2, J. Hayes, Sutton-in-Ashfield.

BELGIAN (Variegated or Marked Yellow).—1 and 2, O. Nicholson.

BELGIAN (Variegated or Marked Buff).—1 and 2, O. Nicholson.

LIZARD (Golden-spangled).—1, E. Hawkins, London. 2, Widdowson and Holmes, Swindon.

LIZARD (Silver-spangled).—1, H. Apted. 2, J. Hayes.

GOLDFINCH MULE (Jonque).—1, J. Baxter, Newcastle-on-Tyne.

GOLDFINCH MULE (Mealy).—1, T. Cordingly, Brighton. 2, Rev. V. Ward, Canterbury.

CANARY OR MULE (Any other variety).—1, H. Vine, East Cowes, Isle of Wight (Cinnamon). 2, J. Baxter (Linnet Mule).

BULLFINCH.—1, Mrs. W. C. Drummond, Bath.

GOLDFINCH.—1, W. Walter.

LINNET.—1, J. Baxter.

SKYLARK.—1, J. W. Harrison, London.

WOODLARK.—1, O. Nicholson.

BLACKBIRD.—1, Mrs. Roe, Southampton.

SONG THRUSH.—1, T. Webb, South Norwood.

STARLING.—1, J. W. Harrison.

ANY OTHER VARIETY.—Equal 1, A. G. Hubbarde (Magpie); J. W. Harrison (Nightingale). 2, O. Nicholson (Cream-coloured Goldfinch).

COCKATOO (Any variety).—1, M. George, London (Lemon).

PARROTS (Any variety).—1, J. W. Harrison (King). 2, W. Walter (Grey).

LOVE BIRDS.—1, W. B. Bailey, Purfleet.

JAVA SPARROWS.—1, W. Walter.

WAX-BILLS (Any variety).—1, W. B. Bailey (St. Helena).

ANY OTHER VARIETY.—1, J. W. Harrison (Bearded Tits). 2, J. Fry, Southampton (Parroquets).

PHEASANTS.—1 and 2, E. Gibson, Ryde, Isle of Wight (Gold and Silver)

JUDGES.—*Poultry:* Edward Hewitt, Esq., Sparkbrook, Birmingham. *Canaries:* A. Willmore, Esq., London.

YORK ORNITHOLOGICAL SOCIETY'S SHOW.

THE following is the prize list of this Show, held at York on the 3rd inst.:—

NORWICH (Clear Yellow).—1, Moore & Wynn. 2, T. Irons, Northampton. *hc*, Pennock & Blackstone, Whitby; E. Orme, Derby.

NORWICH (Clear Buff).—1, J. Bexson, Derby. 2, E. Orme. *vhc*, Pennock and Blackstone; T. Irons, Northampton; J. Bexson.

NORWICH (Evenly-marked Yellow).—1, J. Bexson. 2, Moore & Wynn. *hc*, G. Gayton; Moore & Wynn.

NORWICH (Evenly-marked Buff).—1 and 2, Moore & Wynn. *vhc*, G. Gayton, Northampton. *hc*, Pennock and Blackstone.

NORWICH (Black or Grey-crested).—1, Pennock & Blackstone. 2, T. Irons. *hc*, J. Calvert.

NORWICH (Yellow or Buff-crested).—1, — Clarkson. 2, R. Reed.

LIZARD (Golden-spangled).—1, Clarke & Houghton. 2, Pennock and Blackstone. *hc*, — Ransley; R. Hawman. *c*, Allen & Baines.

LIZARD (Silver-spangled).—1, — Rawnsly. 2, — Hawman. *vhc*, Allen and Baines, York. *hc*, Clark & Houghton.

BELGIAN (Clear Yellow or Buff).—1, F. Fritschler, Beverley. 2, W. Needler, Hull. *hc*, W. Dodsworth; W. Needler.

CINNAMON (Yellow or Buff).—1, T. Irons. 2, — Bexson. *vhc*, — Gayton; R. Hawman. *hc*, Moore & Wynn.

CANARIES (Any breed).—1, Clarke & Haughton. 2, J. Downs. *vhc*, — Brushby; Moore & Wynn. *hc*, Mrs. S. Gadsby.

CANARY (Any other variety).—1, — Calvert. 2, R. Trelschler. *vhc*, J. Greenless. *hc*, — Irons.

Cage of Six Canaries, in Variety.—1, Clarke & Haughton. 2, M. Burton. *hc*, J. Calvert.
Goldfinch Mule (Variegated).—1 and 2, W. Needler. *vhc*, — Bunting; J. Robinson. *hc*, C. Burton.
Goldfinch Mule (Dark).—1, Allen & Baines. 2, Moore & Wynn. *vhc*, M. Burton. *hc*, R. Smith.
Linnet Mule.—1 and 2, — Burniston, Middlesborough. *hc*, Miss M. Gawan.
Goldfinch.—1, R. Hawman. 2, S. Bunting. *vhc*, J. H. Baw; — Burniston. *c*, J. Foster, York.
Linnet (Brown).—1, J. Foster. 2, S. Bunting. *vhc*, J. N. Harrison; — Burniston. *hc*, — Dodsworth.
Parrot (Any colour).—1, Miss E. Hill, York (Scarlet). 2, J. Calvert, York (Grey). *hc*, J. Scott (Grey).
Canary (Ticked or Uneven-marked).—1, J. N. Harrison. 2, E. Orme.
Canary (Clear Yellow).—1, T. Cowl, York. *hc*, S. Hardcastle; J. Mollitt.
Canary (Clear Buff).—1, G. Carr. *hc*, J. Mollitt; W. Clarkson.
Judge.—Mr. J. Barnesby, Derby.

DARLINGTON ORNITHOLOGICAL SOCIETY.

The first Show of this Society was held on the 6th inst., when nearly three hundred specimens of Canaries and British birds were staged for competition.

The Society is only in its infancy, this being its "first step;" and a most creditable attempt it was, the result affording every encouragement to its promoters to repeat the Exhibition next season on a more extensive scale. The Secretary (Mr. W. W. Ellerton), and Committee were most assiduous in attention to their duties, polite and courteous to strangers, and not lacking in firmness and decision in requiring the conditions of their schedule to be acted upon in their integrity by exhibitors, and will, with increasing experience and outside support, which they deserve, make the Darlington Show take a fair position among the North of England exhibitions.

The entries were chiefly from the neighbourhood; but the thanks of the Society are due to those All-England men who make it a point of duty to support every well-conducted show by sending specimens to enrich the exhibition, regardless of the question of expense. Northampton, Sunderland, and Derby each sent its contribution.

The *Belgians* were strong in numbers and quality, the winning birds being in some instances hideous in their beauty. "Wiltshire Rector" once wrote me that he had no special liking to any particular variety of Canary, but was conscious of an intense dislike to Belgians. Now he writes that he regards them with sympathy and not horror. I am afraid he is smitten past all recovery. I can understand a man being enticed by the blandishments of a lovely Clear Norwich, the sparkling dress of a syren Lizard, or the more sober beauty of a modest Cinnamon dressed like a prim little Quakeress; but when he loses his heart to a Belgian hunchback the disease can go no further, and frequent will be the notices to the churchwarden. "Absent on urgent private affairs." But I think if he had seen the first-prize Clear Yellow Belgian when he was "put up" his old dislike would have returned. It reminded me of a scene at our last show, where a lady was very anxious to see a Belgian bird put into position, and a very grand specimen was "put up." But when it began to straighten its legs till its happy owner asserted it would turn its joints inside out, and when it seemed to be making frantic endeavours to get its shoulders over its head, and was evidently bent on dislocating its neck, she took her husband's arm and said, "That'll do, John, that'll do; have him *put down* again!"

The *Norwich* classes were fair, and the prize birds excellent, but I have seen better exhibited by the same names. I suppose they are doing battle at Southampton. The Crested birds were very good, but the wording of the schedule necessitated very "all round" judging, as no special variety was indicated. I always hail the advent of a new name in a catalogue, and especially when it is that of a gentleman of position. Charles Taylor, Esq., son-in-law of George Elliott, Esq., M.P., made his debût in this class with two very creditable specimens. They bore evident signs, however, of having received their ablutions from a 'prentice hand, but for which they would, probably, have taken a higher diploma than V.H.C. and H.C. I hope to see more of Mr. Taylor's stock.

The *Lizards* were a very good sample, the first-prize Golden-spangled notably so, showing strong points of excellence. Messrs. Irons & Gayton were in immense force in Cinnamons, their Jonques being super-excellent. Of the Yorkshire birds I can only say, as I have said elsewhere, that they bore a strong resemblance to inferior Norwich birds, and there was very little pleasure in judging them. The true Yorkshire is a noble type of Canary, and very different from the mongrels often entered as such. The "Any other variety" class enabled Messrs. Pennock and Blackston, and Messrs. Moore & Wynn to win with very fine specimens of Ticked and Unevenly-marked Norwich.

The Goldfinch *Mules* were a show in themselves, though there was only one class for them—viz., "Evenly-marked Buff," the Committee falling into the same error in classification as at North Ormesby. Mr. Young was first with one of his stud, and Mr. Shiel followed with three beauties, which it was hard to separate. The Rev. S. T. Mosse also exhibited a bird which, with time and improved condition, will require a deal of beating. Dark Mules were not numerous, but first-rate in quality. The first prize in Class V., "Any other variety of Mule" fell to a splendid Brown Linnet Mule, backward in condition, but a bird of extraordinary merit—evenly and lightly marked on the wings, and side of the head, and tail, and of extra colour. The clear Greens represented two sections, the Norwich Green, and the common Pea Green. There is a diversity of opinion as to which is the more meritorious bird, and the judgment in this class caused, I will not say dissatisfaction, but a little spirited argument by the admirers of either class. As the common Pea Green bird is that meant in all our northern schedules, it would be as well to state "common" in contradistinction to "Norwich." The former is the favourite home pet of our colliery districts, and the latter the foundation of the glorious Norwich Jonques, and I am glad to see, that in societies where the matter is understood, there is now a separate class for "Norwich Green."

The *Goldfinches* and *Linnets* were numerous and very splendid birds, and the varied specimens in the miscellaneous class were each and all worthy of favourable comment.—W. A. Blakston.

Judges.—Mr. Pearson, Durham, and Mr. W. A. Blackston, Sunderland.

MATCHES OF BARB PIGEONS AT THE PHILOPERISTERON SOCIETY.

These took place on the 9th. Capt. Heaton showed five pairs of old birds against five pairs of the other members of the Society's birds. The Captain's birds were one pair of Reds, one pair of Duns, and three pairs of Blacks. The other members showed against them two pairs of Reds, one of White, and two of Black. The decision on these was an easy matter for the three gentlemen who officiated as Judges—Messrs. Wiltshire, Esquilant, and Tegetmeier, for with the exception of one Black cock and a Red hen, belonging to Mr. Headley, which were two extraordinarily good birds of their age, the Captain's went clearly before the others. No one could avoid remarking what a splendid pair of Reds the Captain's were, and his Dun hen is no doubt the best Dun hen in the fancy: in fact, the only old birds he showed that were not extra good in all points, were the Dun cock and his old Black cock, their forms being bad in skull and coarse. The Black cock is the remains of an extraordinary bird for skull and eye.

Next came the young birds of 1868, the Captain showing one pair of Yellows and three pairs of Black against four pairs of the same age of the other members. In these the Captain

won in cocks, and the other members in hens. Of these birds, if the owner have patience to keep them for two or three years, he will have birds of which a Barb-fancier might be pleased to have a sight.

Next came four pairs, each of birds of 1869. In these Messrs. Jones and Headley easily vanquished the Captain in the cocks, and in the hens the merit was equal. The Captain cannot have too much praise for his pluck in challenging and defeating the most of the members of the great Philoperisteron Society in the friendly manner he has, and the manner in which the defeated members acknowledged their defeat was most praiseworthy.

RABBITS AND THEIR VARIETIES.

When speaking of the fancy Rabbit we always associate it with being exhibited, so that as an introduction to any remarks I make in reference to any particular variety it may not, I hope, be deemed out of place to say a few words respecting shows, more particularly the want of uniformity in the scale of entry fees.

I fully admit that all committees think they are fixing the proper charge, but I cannot understand why there should be such a vast difference in the opinions of committees; for instance, I have before me schedules containing entry fees, showing the almost incredible difference between 6*d.* and 10*s.*, a £3 first prize being offered in the latter case, a five-shilling one in the former; the one far beyond the speculative feelings and means of many would-be exhibitors, the other deemed unworthy of notice. The entry fee is certain in its payment, but the prize not so sure. I incline to the belief that a tenth is about a fair proportion of the prize as entry fee, or what we often now find—viz., a £1 prize and a two-shilling entrance fee. And why, I should like to ask, do we find such differences made in the prizes awarded when the same fee is exacted for all? I have seen schedules in which the Lops are to receive a £1 prize, the other varieties 10*s.* Now justice says, Make them all alike in awards if equal in entrance fee, or at least assign a satisfactory reason to the exhibitor why the inequality should exist.

I often think committees to some extent fail in rendering their shows so attractive to the exhibitor as might be done with a little more judgment and care in fixing the scale of entries. No doubt a great similarity is found in issuing a schedule of entries and awards to putting forth a programme of any entertainment. The first point is to convince the exhibitor that it is worth his while to enter his stock, feeling that the entrance fees and awards are proportionate to each other, leaving the result to the knowledge of the judge, who gives the finishing touch to the weeks' or months' toil on the part of the committee. In the case of the pleasure-seeker, he also wants to feel convinced that his fee for admission will be fully repaid by the pleasure derived from the entertainment. I think the above hints are worthy of notice by committees, and that acting on them would conduce to the success of their shows.

I will now continue my remarks on the varieties of Rabbits.

Dutch.—"The pretty little Dutch!" say all who look upon these diminutive specimens of the Rabbit family. It is small, but very attractive, wonderfully docile, and very amiable in disposition. It is originally from Holland, but is also found and reared very extensively in France under the name of Nicard. It is much esteemed in Old Provence, and valued for its hardy and prolific nature. The does are excellent mothers, generally rearing from six to eight young, and are also excellent nurses. I would recommend all fanciers to have a couple of these mothers having litters at the same time as their other valuable specimens, for fear of accident, or there being, perhaps, too many for the doe to rear, especially if intended to be "extra strong" for exhibition. Then the maternal affection of the Dutch doe may be relied on, as she cares for the well-being of the helpless progeny of another doe overburdened with a large family. They are of various colours, as tortoiseshell (which in the estimation of some is the perfection of marking in this variety); blue, with a white ring round the neck; grey and black, with a white ring; and at times the body is dotted over with—say, blue and white, which gives Rabbits of this breed a pretty appearance. The marking seems to be a little uncertain, like that of the Lop or Angora. Of the former, the marking is frequently made the subject for a separate class and prize at shows (not forgetting other points, of course); whilst the Angora, as I have previously stated, receives its prize irrespective of colour.

At present our judges seem at a loss as to the points of the Dutch, and at times I think it would be well if committees would have two classes for them—say one for tortoiseshell, and the other for any marking, as a blue, grey, or black body, with a white ring round the neck. This ring is at times not complete; a few hairs, perhaps, behind the ears, of the same colour as the body, forming a kind of buckle as if to attach the white collar. The perfection of this ring might be the point of excellence, if the specimen were perfect in other respects.

I am glad to find that this variety is now receiving the attention its beauties deserve. At some shows a distinct class is given for it. I should be glad to find all the fancy Rabbits represented at such periodical gatherings, and have no hesitation in saying that if properly invited by a distinct class, they will be in prompt attendance for the judges' opinion.

By breeding in-and-in this variety may be reduced to a very diminutive size. This by some is considered a point of excellence. I have heard of specimens weighing less than 1½ lb. I do not wish for them of less weight than 2½ lbs., and cannot perceive the advantage of reducing them to a weight so much less than the natural size.

The Himalayan and Silver-Grey will form the subject for a few remarks ere long.—Charles Rayson, *York Mount, Prestwich, near Manchester.*

SPURIOUS HONEY.

I have directly not a word to say regarding this controversy, as to the merits of which I am indeed profoundly ignorant, but I wish to confirm what has been stated by "A Manchester Man" regarding Mr. Pettigrew, who is to my own knowledge a bee-keeper of very many years' standing, and of great practical ability. He is also, as most of us are aware, a man of original ideas, which, although they may not invariably be correct, he does not shrink from propounding openly, and advocating earnestly, fairly, and honestly. It must, therefore, be apparent that it is simply absurd to say of such a man that he should not assume to give information to others on the subject of bees, and I should be very sorry if anything which has transpired should tend to discourage his contributions to "our Journal." For myself, I can only state that I have always perused them with pleasure not unmingled with profit, and that I have reason to know that they have proved instructive to many others as well as to—A Devonshire Bee-keeper.

AN OLD STOCK IN A COLLATERAL HIVE.

I have a stock of bees which I want to transfer, increase, and manage better. When I attempt to do anything with them the points at their tails keep one in mind of their powers for a few days, for though I encase myself in a bee dress, &c., being close to a road, very frequently I have heard parties wish them gathering honey in some other place but there. I have this season taken off some 45 lbs. of honey from one swarm, which I do not consider bad. They have been in the same box about ten years, and I fancy the combs are too full to leave space enough for a large brood, although, as far as I know, they are healthy and strong. When I take them off the stand, is there any plan by which I could cut any of the comb, as I fear their active attacks will spoil my pleasure, I knowing of nothing to stupefy them, and so remove them? The centre box I keep full of honey; it weighs about 40 lbs., it has slits on each side, through which the bees pass into two side boxes; these I take off every year, and this with 45 lbs. is no exception—I have done the same for years. They have never swarmed but once, and that swarm I have had no honey from for two years. Where can I procure a Woodbury hive? I will then with instructions try to put the swarm into it, and if I procure a Ligurian queen, should I have any chance of uniting it to this stock?—October.

[We fancy we should leave the bees alone in the old hive (which appears to be a Nutt's collateral, and to have been an old and faithful servant), if it were only to see how long bees will thrive in the same combs. As soon as the colony again becomes populous—say towards the end of April, or in May, according to the season, you may, however, transfer the bees of the swarm to a Woodbury hive in the manner described in page 72 of our present volume. Messrs. Neighbour, 149, Regent Street, and 127, Holborn, and Mr. Pettitt, of Dover, supply Woodbury hives, or you may write direct to Mr. Wood-

bury, at Exeter, who would also obtain for you an Italian queen, and advise you as to uniting her.]

BEE-KEEPERS' CONVENTION, LONDON, CANADA.

This convention met according to notice on Tuesday, September 21st, but adjourned in favour of the fruit-growers' meeting held at the same time.

The Committee appointed to draft a constitution and bye-laws, and recommend officers for a permanent bee-keepers' association, beg to report as follows:—

CONSTITUTION.

Art. 1. That this organisation be called the "Ontario Bee-keepers' Association."

2. That the object of this association shall be to promote the interests of scientific and practical bee culture.

3. That gentlemen paying 50 cents yearly shall be considered members of this association, Ladies to be admitted to membership free of charge.

4. That the officers of this association shall consist of president, vice-president, secretary, treasurer, and a committee of five, three to form a quorum—who shall be appointed annually.

5. That this association shall meet annually at the time and place of the Provincial Fair, or oftener, at the option of the committee.

BYE-LAWS.

1. The order of procedure at the annual or public meeting of the association shall be, first, the transaction of business, and then the discussion of questions pertaining to the science and practice of bee-keeping.

2. Any member of the association shall be entitled to send notice to the secretary of a question or questions for discussion at an approaching annual or other public meeting.

3. Questions previously prepared, and of which public notice has been given, shall take precedence of other subjects of discussion at the meetings of the association.

4. Any person proposing a question shall, if present, be expected to introduce the subject.

5. No person shall be allowed to speak longer than ten minutes at one time on any question.

6. The association shall have the power to change or add to the constitution or bye-laws at any annual meeting, notice of such change or addition having been given at least twenty-four hours beforehand.

The discussion of questions was then resumed. After a lengthy and pleasant discussion of the question, "What is the best method of artificial swarming?" it was moved and carried that it be laid upon the table.

The question "Has foul brood ever been discovered in Canada?" was next submitted. As several members answered in the affirmative, it was then resolved, that cases of undoubted foul brood having been reported, this association would strongly urge the total destruction by fire of all stocks and hives affected by this dread scourge of bee-keeping, so as to prevent its spread.

The question of the best size of hives for Canada was then discussed at considerable length, when it was moved and carried that a hive containing about 200 cubic inches is the best for Canada.

THIRD SESSION.

Pursuant to adjournment, the Ontario Bee-keepers' Association met on Wednesday evening at 7.30 o'clock, when the minutes of the last meeting were read and approved. Several items of business being disposed of, the question "Do bees consume less and come out better wintered in a uniform cool or in a warm temperature?" was discussed. After a brief discussion it was resolved that bees winter best in a uniform cool temperature. The question "What kind of plants will honey the best in excessively wet weather?" was next considered. After a short discussion it was resolved, that in the opinion of this association the locust, currant, raspberries, and berry plants in general, sweet clover, and American bee plant, are the best plants for producing honey in wet weather. The question "What is the best method of securing the most surplus honey after having doubled your swarms?" was taken up. After a spirited discussion it was resolved that the best method of obtaining surplus honey is by using large boxes on new hives, and taking honey from old hives by the honey-extractor. The question "Is the centrifugal comb-emptying machine as useful as has been represented?" was then considered. After several replying in the affirmative, it was resolved that we regard the honey-extractor favourably, and recommend its favourable use. The last question brought before the association was—"Is a plain hive the best for successful bee-keeping in Canada?" After an exceedingly interesting discussion a resolution was passed with one dissentient, that a moveable comb hive, and not a plain hive, is best for successful bee-keeping.

After having enjoyed three very interesting and profitable sessions, with an average of sixty intelligent bee-keepers, thirty-five of whom enrolled themselves as members, the meeting adjourned to meet again at the time and place of the next Provincial Fair.

OUR LETTER BOX.

Feeding Fowls for Exhibition (*Cymro*).—You should be rather more explicit, and tell us what breed the birds are. In some you would want to make weight, in others to make hard plumage. Dorkings, Cochins, and Brahmas would belong to the former; Game, Malay, and Spanish to the latter. One thing they have in common, they should be fed four times every day. The first meal should be at daybreak, the next two should equally divide the day, leaving the fourth for the last of daylight. No meal should be so plentiful as to make them leave any, nor should they even be thoroughly satisfied. It is an excellent plan to throw them a piece of bread or some crumbs three or four times every day, only a little, but it does them good. We shall suppose your pen is a pen, being, in short, nothing but a place in which fowls may be confined. As the object is to cause the birds to improve, even as compared with those that are at liberty, it will become immediately apparent they should have everything the others have. Some bushels of road grit should be thrown down. Large sods of growing grass should be cut and thrown into the pen every day. They should be well supplied with fresh spring water. For ordinary fowls, give ground oats slaked with milk, cooked meat chopped fine, bread, and a handful of maize now and then. If the ground oats or barley meal can be slaked in pot liquor, so much the better. Some steamed greaves often do wonders in making weight. To all must be added, where hard feather is sought, a few peas every day; and a raw egg or two—the yolk of them only, will sometimes do wonders for a Game cock.

Houdans Giddy and Paralysed (*H. S. F.*).—All the French breeds are subject to these attacks. The La Flèche are the worst. Our treatment is to give bread and ale, and Baily's pills. A most essential point is to take away their water, and allow them to drink a little only three times per day, and that strongly impregnated with camphor. You will see when they are taken they go to the edge of the vessel containing their water, and take their stand there, drinking every minute. It continues the disease, but the absence of water is the beginning of the cure. We left one of our best pullets this morning just as you describe yours. We took away her water—she will be well to-night.

Fowls and Guinea Pigs Killed (*G. F. T.*).—We believe you are suffering from the depredations of hedgehogs. We were the victims of such visitations for a long time, and it was only after watching some nights we discovered it. That was in a lonely orchard. We have in London pets and pests; among the latter we reckoned black-beetles, and were advised to try a hedgehog. We did so—from the day we did so we had mysterious deaths and disappearances. At last we found the delinquent. He killed and partly ate a pair of Carolina Ducks, and yielding to the feeling of ease following a copious meal, he composed himself among the down and feathers, and went to sleep. Hence the discovery.

New York Poultry Show (*H. B. M.*).—Write to Mr. Tegetmeier, who, we believe, is London Secretary.

Poultry Farm (*Young Nemo*).—You can keep two hundred adult fowls on four acres of grass. We hope soon to hear of poultry-gardening, believing that the surface may be increased by inequalities, and shelters, dusting places, and refuges artificially provided, the whole subject to a law that there shall be no hollow or damp place. We do not hold with crosses. If you are satisfied that Hamburghs and Spanish are the best layers, why not keep the latter on account of the size of their eggs? An egg is an egg on paper, but it is by no means the same at breakfast or in a pudding. We believe six Spanish eggs are equivalent to ten Hamburghs. Eggs at this time of year, or, indeed, always, should be sold by weight. For table you want Dorkings or Brahma Pootras. These both sit their own eggs. Crève-Cœurs and Houdans are both excellent layers, but do not sit. We are in the habit of keeping eggs in slaked lime, but not lime water, and they do not taste. We have been told eggs covered with butter or gum keep equally well. We have never tried either.

Points of Light Brahmas (*Inquirer*).—The only difference in points of Brahmas, as between Light and Dark, is in colour. The Light variety should be white with the following exceptions:—The flights and tail should be black; the hackle striped with black; the feathers of the legs light outwards, dark underneath. In every other point they are alike.

Aylesbury Duck's Eggs Unfertile (*A Disappointed One*).—The eggs are very large, but we have seen single Spanish hen's eggs nearly as large as some of them. We have had Ducks, hens, and Geese laying double eggs frequently, but have never known them to continue it always. It is a derangement of the system. We should not hesitate to breed from the same birds again. Laying double eggs is by no means a sign of barrenness.

Exhibiting Ducks (*October*).—From your description we should think No. 1 the best birds, and we consider the hole in the web of the foot quite unimportant. We presume, from your speaking of bills, they are Aylesbury Ducks. If so, it is far better to have black spots on the bills than to have them discoloured. The weight is hardly enough; you want at least 2 lbs more. The loss of the tips of one or two toes would not interfere with the hopes of success for a bird; but if all were missing, it would certainly be a disadvantage.

Andalusians.—We are informed that "H. P." can obtain what he requires, if he write to Mrs. Kirkman, Malton, near Woodbridge, Suffolk. We do not know her birds.

Ground Oats (*R. A.*).—We congratulate you on having succeeded in grinding the whole of your oats. The husk reduced to fine meal is among the most valuable parts of the corn. It is better to give it mixed with water, and it is also more profitable.

Feeding Bees (*L. M.*).—The best mode of feeding is by means of an inverted bottle, as described and figured in page 21, of "Bee-keeping for the Many," which may be had post free from this office for five stamps.

Elder Wine (*Subscriber*).—We believe that Elder wine that has not fermented with yeast, will ferment spontaneously, as do the wines of foreign vintages.

POULTRY MARKET.—November 10.

We have a good supply and a bad trade.

From observations taken near London during the last forty-two years, the average day temperature of the week is 48.5°; and its night temperature 34.1°. The greatest heat was 61°, on the 20th, 1863; and the lowest cold 9°, on the 23rd, 1858. The greatest fall of rain was 0.95 inch.

UNHEATED ORCHARD HOUSES.

IF we may judge from the season experienced in the Channel Islands, it may be said that never since the first introduction of orchard houses has Peach culture in them experienced such great difficulties. Here we had a damp and gloomy spring, succeeded by a sunless summer, and this by an unfavourable autumn remarkable for the most furious hurricane ever felt here. Hail showers and low temperatures closed in the record of this trying fruit season with a grim appropriateness. It would have been indeed too much to expect anything like ordinary results in orchard houses without artificial heat, whatever others may have done. As, nevertheless, several correspondents have recorded in these pages their usual success, in spite of every natural obstacle, I am glad to be able to add my own testimony. It would conduce to the interests of fruit-growers if some experience were gathered from these different results, and if future builders of orchard houses without fire heat would study these data. I, for one, am far from thinking that the present style is final or exhaustive of the question. Great amounts of time, labour, and money are now invested in orchard houses, and the capacities of these should be more carefully ganged than is the case at present.

To my mind the main fault lies in the unreasonable expectations formed respecting the powers of production of orchard houses. We hear of fabulous crops—Peaches by the peck (size not stated, nor quality)—but seldom of steady and uniform rates of bearing, which, after all, are as much a true test of skill in the gardener as they are agreeable to the employer; not to say by far the most profitable in the end. Can anything be more opposed to the aim of orchard-house culture than to utilise (?) these valuable buildings for something of every kind that can be crowded into them? yet many gardeners are compelled from want of other space to have recourse to this expedient. Vines will sometimes bear well in orchard houses, but generally at the expense of the Peaches. The same thing may be said of the other fruits. The presence of bedding plants is fatal to the setting of the Peach crop. Potted trees increase in lateral development, but the number remains the same, and then two or three seasons of overcropping, and the trees may as well be used as fuel.

I do not think that there is now a general want of skill in the management of orchard houses; the present magnificent succession of fruits was literally unknown when I commenced this culture; glass is cheap, information is abundant, and a short trial will readily test either the tree or the description of it in the catalogue. There is no reason, therefore, why any should lay the blame of failure save on his own neglecting to note accurately what he sees before him, and so to judge for himself. I believe the great cause of ill success to be the haste which we all experience to see some return for money and time expended, which induces us to exact from young trees too heavy crops. In many places which are much visited, efforts are unavoidably made to secure a fair show at the expense of the trees' future welfare, and blank spaces generally attract visitors more than real excellence of culture, and invite the easy but vexatious criticism of the ignorant. Let the gardener, especially in the orchard house, harden his heart against either his friend's sympathy or his suggestions when he places unreasonable standards of perfection before him. Let him work to attain a steady rate of production, neither exhaustive nor yet below some fair rate of crop. Let him, above all, take the criticisms of visitors at their true merit. This sounds like hard doctrine, but it is the result of an experience of many such matters.

And what grounds, then, will my friends say, have I now for still recommending this careful noting of facts for self-guidance; this practice of steady, in preference to spasmodic, production; and this careful adaptation of the structure of an orchard house and its contents to ranges of climate and its powers of bearing? I will proceed to mention them.

It is too often supposed that the fruit-growing powers of the Channel Islands are so great that little skill is needed to produce almost anything. This has mainly arisen from the reputation of our noble Chaumontel Pears, which happen exactly to suit our cloudy summers and equable night temperature; but for most other fruits the south of England is our equal, and in almost every garden production France and Belgium are naturally superior. Apricots here will rarely succeed on the open wall; open-air Grapes are inferior to those of England. The prevalence of strong sea breezes laden with salt is opposed to success. The hurricane of the 12th of September last, which exceeded a hundred miles an hour in speed, destroyed every leaf which was exposed to it, and shook down most of the crops. Last year, also, a gale occurred in the middle of August. Even in the case of orchard houses, the spring was disastrous, gloomy, and cold, while the summer was nearly sunless; in the month of October we had smart hail showers, and have now violent wind. All these matters are troublesome in the extreme for orchard houses, and render it necessary to exercise continual watchfulness in ventilation and watering. The excellent crop which I had cannot, therefore, be fairly placed to the credit of nearly spontaneous production as being usually common in the Channel Islands. As early as the 12th of June (a date never before reached here), Early Beatrice Peach ripened; and, as I write, two fine baskets of late Peaches (the only ones there), have just been exhibited at the Jersey Horticultural Show. This makes five months' succession of Peaches and Nectarines—not a bad test of the value of unheated orchard houses. It was, indeed, strange to see these trees in full bloom under a February's cold sky, and ripening well under hail and storm in November—ten months!

Not only was there this long period of bearing, but the whole of the fruit was of full size, and of very good colour. Early Rivers and Exquisite, two of the finest Peaches ever seen in England, were especially fine. The first, ripening on the 1st of July, reached to 8½ inches round, perfect, delicious—as the Rev. W. Kingsley, an excellent

judge, also says—and in every way likely to be our best early Peach. Exquisite, from Georgia, is, I think, the finest of Peaches for splendid colour and melting vinous juice. This season it reached 12 inches round, being finer than ever, and the largest Peach ever seen here. So much for quality of fruit. As to number, it absolutely would have equalled, if spread over a trellis, two and a quarter fruit per square foot. In an orchard house of 100 feet by 30 this would have been something enormous. My house is, however, a lean-to of only 15 feet in breadth. Thus, if it be not too much to triumph over, many friends and others who have at least twenty times the area of glass that I have, and still have hardly one Peach this season—and this in earliness and lateness of production, in single specimens and general excellence, and in amount of crop—it would be hard to say where each or all these could be surpassed. Such facts warrant assertion, and prove that certain conditions must not be transgressed if good results are expected. The trees, in fact, were in steady bearing condition, had never been overcropped, had been much thinned, and this disastrous year did not affect their general vigour.

Another point must not be forgotten. The bulk of the crop was borne on cordons, and the potted trees treated as auxiliaries only. The diagonal cordons on the back wall gave the earliest and the most fruit. The spiral cordons in the borders furnished the latest. Standards, which had been many seasons in pots, and had been closely pruned, had that inward curl of root which takes seasons to develope, and thus grew slowly, and bore well. This makes all the difference when we come to plant-out in borders. Trees planted in a young state, and allowed to develope, must end by defeating their pruners. This is the great secret of success in cordon training—from the outset all rampant shoots are kept under and equalised. There is no way of training so easy as this, nor so adapted to economise space under glass. The regularity of form is exactly what we want here. It is not one-half so difficult as training a pyramid or bush.

In speaking of cordons we must not forget that there are some kinds which are most productive. The low lateral bears fine fruit, but not so many as the diagonal. Again, the small, closely-pruned diagonal I have of late abandoned for a form of this shape having longer shoots and more of them. This gives vigour to the tree, and such have the best chance of regular bearing, besides being better able to overcome the attacks of insects. Some of these old trees—the oldest in England—are of good dimensions being thus expanded; and each alternate cordon being advanced 18 inches from the wall allows freer play to its neighbour. Potted trees will bear well for a time, but will not endure the amount of crop taken from large cordons planted in borders. The difficulty in regularly watering potted trees induced me to treat them as auxiliaries only in respect to profit, as three-quarters of our crop was sent to Covent Garden, the remainder being ample for our own wants. With cordons in the borders, having a supply of water turned on into gutters passing by them, as we do here, there is little risk of neglect.

There is every prospect of a good crop for next season.—T. C. Bréhaut, *Guernsey*.

SOME VARIETIES OF FIGS.

As the season for ordering new trees has now arrived, it may, perhaps, interest some of your readers if I make a few observations on several varieties of Figs which I have cultivated, and the greater part of which were obtained from Mr. Rivers. I must premise that the trees are in pots, and in a moderately-heated orchard house. Varieties which do not bear freely under such treatment, as Brunswick, Castle Kennedy, Figue d'Or, have been consigned either to the open wall or to the faggot heap. The following is a list of those that fruited in the house this year. They are placed in the order of their ripening their second or autumnal crop, which, under glass, is the most important one:—

Early Violet.—August 6th. Very small but high-flavoured. This I believe to be synonymous with Malta.

White Marseilles.—August 17th. The first variety ever introduced into England. The sexton of Tarring informed me, that in the exceptionally warm season of 1868, a standard tree there ripened 150 dozen of the second crop. I have also ripened a second crop in an unheated boarded orchard house. The fruit is very sweet, but with hardly any flavour. Flesh white.

Early White.—This variety was rather popular in the last century, but is now seldom seen. The fruit much resembles White Marseilles, and is, to my taste, at least its equal. The foliage of the two varieties is quite distinct.

Pastelière.—Tree ill-shaped. Leaves ill-shaped and often discoloured. Fruit middle-sized, yellow, and downy, becoming nearly black. Quality good, but most of the fruit dropped off imperfect.

Du Roi.—Vigorous growth. Fruit white inside, about equal to White Marseilles.

Dorée (Nobis of Rivers).—Another vigorous grower, but with small, flattened, yellow fruit. Skin thick. Ripens to a sweet-meat.

Black Provence.—Small compact growth, the very model for a pot tree. Fruit small, elongated. When ripening the prominent veins first become black, giving the fruit a singular appearance. Unless very highly ripened it has a disagreeable taste, like a Fig leaf.

Bourjassotte Grise.—Fruit of a good size, colour dingy, quality most excellent. Well deserving the commendation bestowed on it in the *Gardeners' Chronicle*, December 5th, 1868.

Barnissotte Grise.—Another excellent fruit, but not quite equal to the former. The foliage is not healthy, and spots readily.

White Genoa.—Foliage pale green. Fruit yellow, with pale red flesh. Eye, pretty and pinkish. Quality good, but fruit liable to crack.

White Ischia.—Fruit small, pale, and discoloured. Flesh pale red. Quality so excellent that one cannot but regret that this sort must be grown in heat, and, therefore, that so few of our countrymen can ever enjoy it. It may be fancy, but the taste seems to me to resemble a delicate Fig and a ripe Mulberry melted into one. It is known to systematic botanists that there is a great affinity between the trees which bear these two fruit.

Jerusalem or *Figue Goutte.*—Noble foliage. Fruit green, elongated, pale inside. Eye usually closed with a drop of sugary gum, whence its second name. Sweet, but without much flavour.

Ronde Noire.—Medium size, dusky. Flesh pale. Quality good.

Brown Turkey.—This well-known variety requires no description. For the open wall it is without rival; but, strange to say, of all the varieties I cultivate under glass this is the least satisfactory. The fruit swells, colours on one side, but remains green on the other. The flesh does not become juicy, but is solid. The same defect is found both in the first and second crop. Nevertheless, among much rubbish a few fruits ripen to perfection, and I have observed that these excellent Figs are often situated immediately below the joints where the branch has been stopped, and that they ripen before those situated lower down. I have asked advice as to the defect complained of, but have never been able to get a satisfactory reply. One adviser suggested that there was something the matter with the roots, but as there were about eight trees of Brown Turkey in the house, there is no reason to suppose that their roots were in a more unfavourable situation than those of other varieties. I remember, however, having seen in your pages a statement that Figs exposed to bright sunshine ripened prematurely and imperfectly. This seems improbable when we consider that in foreign countries Figs flourish most under hot, cloudless skies. Nevertheless, it is supported by the fact, that a dozen Brown Turkey trees which I keep back in spring, and which are brought into the warm house to ripen towards the end of October, when the power of the sun has declined, not only in general ripen their fruit well, but these are much darker in colour than those which ripen earlier.

Œil de Perdrix.—September 7th. Plant short-jointed and sturdy. Fruit reddish brown, but without any peculiar beauty of eye, such as one would expect from the name. Flavour good, reminding one of the White Ischia. Liable to crack, and in consequence of the fruit being sessile on the branch, the lower part ripens with difficulty. The last fruits are the best.

Gourreau Rouge.—Medium size, reddish brown, good, but not high flavoured.

Datte.—Green, flesh red. Good.

Grosse Verte.—Green. Flesh dark red, very liable to crack. Last year, by paying great attention to watering, I obtained most excellent fruit. This year I have not been so fortunate. One plant which had not quite water enough produced fruit fully swollen, but deficient in flavour. The other must, I suppose, have had a trifle too much, and the fruit split; so that it is steering between Scylla and Charybdis.

Gourreau Noire.—September 20th. Elongated, black, with a beautiful bloom, desirable both from its colour and its quality.

Col di Signora Nera.—October 7th. Large, chocolate brown, swollen at the neck; quite a sweetmeat.

D'Agen.—Green, with red flesh, and good. Though one fruit ripened on the 17th of October, no other has ripened up to the present time (November 10th). It is too late for general cultivation.—G. S.

AMATEUR ROSE-GROWING.

A THOROUGH florist and a most successful cultivator and exhibitor is Mr. Charles J. Perry, of Castle Bromwich, Birmingham. With the Verbena, Dahlia, and Rose, Mr. Perry may truthfully be said to excel, and he *does* excel. He has raised some of the finest Verbenas ever sent out, and he has made good contributions in the form of new Dahlias; he is also a raiser of seedling Roses, and though he has not as yet secured floricultural immortality in this direction, yet as an exhibitor he has won many a fight in the modern edition of the wars of the Roses. Though Mr. Perry grows a great many standard Roses, yet his chief reliance is on dwarf Roses on their own roots, grown on the "pegged-down system," one by no means new, but well deserving of being more generally adopted, especially by exhibitors. I paid Mr. Perry a visit about the middle of July last, and the glorious floral display his huge bed of pegged-down Roses presented, was one seldom to be witnessed. It was, indeed, as if summer had come forth

"All wreathed in a thousand flowers,"

the hue of the Rose seemed to blend with the fragrance of the Violet, and shed a luscious balm around.

All Roses to be grown on the "pegged-down system," should be, and are with Mr. Perry, on their own roots. By following the plan adopted at Castle Bromwich, it is by no means difficult to have dwarf Roses on their own roots. Early in November cuttings are taken, selecting wood of an intermediate development, what Mr. Perry calls "neither too hard nor too soft," and these are placed thickly in lines in any part of the garden where the soil is good. They can be placed between lines of dwarf-growing plants, if sufficient space be allowed them. A good proportion of these will strike; if only half of them, the propagator has little reason to be dissatisfied. By the following November the rooted plants are ready for transference to the beds. Mr. Perry prepares his beds by digging into his soil, which is a kind of red clayey loam, a good dressing of old frame manure and marl, and he recommends, where the ground is light, a good dressing of decayed cow manure. The plants are placed not less than from 2 to 2½ feet apart, and in the spring they are cut down to two eyes. During the summer these plants show shoots from 4 to 6 feet in length, which are pegged down in the following February, but pegged so as not to root into the ground, being brought only to within 3 or 4 inches from the ground, by using strong pegs cut out of old pea sticks. The shoots so pegged down are cut back to four or five eyes, and during the summer it is nothing for them to make shoots from 6 to 8 feet long. From this time, the pegged-down Roses may be said to be fully established. During the winter, when there is not much else to do, all the old blooming wood is cut away, leaving only three or four of the strongest shoots made the previous summer from the roots. This is done by Christmas, or soon after. Then, after the old wood is cut away, a coating of manure is slightly forked in among the plants, and the shoots are pegged down in the February following.

What are the advantages of this system of pegging down? it may be asked, and in this relation Mr. Perry's experience may be given in reply. He asserts—1st, That by adopting this system the flowers and foliage of the Roses are brought close under the eye, as the flowering wood comes from the horizontal shoots placed in this position by being pegged down. 2nd, The soil round the roots of the Roses is so effectually screened from sun and wind, that it is always cool and moist, even in the driest weather. 3rd, The Roses so treated bloom both earlier and later than by any other mode, as the points of the rods always produce their flowers before the base, and when the shoot from the base of the rod has bloomed, the "stools" or roots throw up strong young shoots that continue to bloom up to Christmas nearly, if the weather be at all favourable. (It is these young shoots that are pegged down the following spring, when they are shortened back about a foot to get to the matured wood.) 4th, Roses so treated may be said to last for ever. Some of Mr. Perry's plants, those on which he mainly depends for a supply of blooms for the earlier exhibitions especially, are ten years old, and yet are as good as when first planted, and throw shoots from 6 to 8 feet in length; in fact, they look more like climbing Roses, so vigorous is their development, and these shoots yield magnificent blooms in the autumn.

Mr. Perry shows his faith in this system by growing a very large number of Roses in this way, and his reliance upon it may be illustrated by stating, that up to July 17th of this year, he had taken ten first prizes as an exhibitor of Roses, including four silver cups, that he commenced to exhibit at Leeds on the 9th of June, where he won three first prizes, and all this had been done mainly by flowers cut from plants treated on the pegged-down system. How rapid and vigorous is the growth may be shown by stating, that on July 17th I saw a shoot from a stool of Louise Odier that measured 6 feet in length, while others were not much behind it.

"Be sure," says Mr. Perry, "never to plant Roses in this way, except they are on their own roots." Roses on the Manetti stock have been a great source of trouble to him, and he has long since abandoned their use altogether for pegging-down purposes. The strongest growers are always the best for this purpose, such as Madame Clémence Joigneaux, John Hopper, Général Jacqueminot, Senateur Vaisse, Madame Charles Wood, Comtesse Cécile de Chabrillant, Jules Margottin, Monsieur Bonceune, La Reine, Emotion, Souvenir de Charles Montault, Jean Goujon, Madame Julie Daran, Louise Odier, La Tour de Crouy, or any moderately robust grower. Tea Roses must not be employed for the purpose. Mr. Perry has never known a single instance of a Tea Rose succeeding when subjected to this process. In a paper contributed to the "Florist and Pomologist," for August last, Mr. Perry gave the outline of his process, and added, "Perhaps the cause of the pegged-down system not being more general, is the length of time required to bring the plants into perfection—viz., three years; but against this drawback the cultivator must consider that they never wear out, as the young wood only is each year pegged down, all the old blooming shoots being cut away. Some of my beds have been planted twelve years, and are in as fine condition now as when they were three years old."

But standard Roses are by no means neglected at Castle Bromwich; they are indispensable for the newer kinds of Roses, and they are always of great value at certain seasons to the exhibitor. Mr. Perry finds it best to plant the Briars before budding where they are to stand permanently; they root freely and finely into the ground, and are in no danger from being disturbed. This opinion was also held and acted upon by that fine and successful amateur Rose cultivator, Mr. J. T. Hedge, of Reed Hall, Colchester. Standard Roses, in Mr. Perry's opinion, should be on stems not above from 3 to 4 feet in height; he thinks that more vigour belongs to a stem of this height than one taller and more exposed. I asked Mr. Perry, while pleasantly discoursing about Roses, if it were possible to grow standards on their own roots, though, perhaps, in some danger of being thought a veritable tyro for my pains. He said he had never tried to obtain them so, but had essayed to bud on the old wood of dwarfs, and then peg the shoots down; the buds would start into growth, but in severe weather the shoot made by the bud was destroyed at the point of insertion in the stock, perhaps, because of the incision made in it.

In regard to the pegging-down of Roses, Mr. Perry recommends that the strong succulent shoots likely to be affected by frost should be cut away (the late growth is here referred to) and that pegging-down should not be attempted till all danger from frost has passed away, the danger being greatest at mid-winter.

With other floricultural weapons Mr. Perry wins many a hard-fought fight. As an exhibitor of Fuchsias he deservedly ranks high, and that not by exhibiting old plants of some three or four summers, but specimens 4 feet in height, and splendidly furnished, obtained from cuttings struck the previous autumn. With Zonal and large-flowering Pelargoniums he is rarely beaten, and as an exhibitor of Verbenas he is seldom excelled—never surpassed.—VIA.

AUTUMN CROCUSES.

I COULD assist the author of the article on autumnal Crocuses ("M. H.," *Acklam Hall, Middlesbrough-on-Tees*), in collecting the autumnal-flowering Crocuses. I might send him Crocus Kotschyi, C. cilicicus, and C. Boryi, autumnal flowering; C. reluchensis, C. reticulatus reflexus, and, perhaps, also Crocus iridiflorus major, and various Colchicums. All these

are, however, planted in the open border, and cannot be sent before next summer.—Max. Leichtlin (*Amateur Collector of scarce Bulbous Plants*), *Carlsruhe* (*Baden*).

PEACHES AND NECTARINES OUT OF DOORS IN 1869.

The past season will be memorable for many years. I read with great interest the causes to which the fruit-failure was attributed by our best gardeners. Some attributed the failure to the non-ripening of the wood, some to winds blowing away the pollen, and some to the wetting of the pollen. Not one of these was the reason. Wood was never better ripened here. Winds are most violent here, but that could not affect trees in orchard houses; and the same may be said in respect to wetness. The few Peaches and Nectarines that set here were situated where rains could easily touch the blossoms.

The following I believe to be the cause of failure—a want of heat—geothermal heat, or earth-warmth; for in heated houses the crops of Peaches and Nectarines were excellent, but out of doors and in unheated houses, with rare exceptions, the failure was general.

Here the Peach and Nectarine trees, in number about 127, were in full bloom by February 1st. I never saw a more beautiful floral sight, extending over 170 yards of wall. The blooms, with sheets over them on running rings on rods top and bottom, kept perfectly fresh for ten or more weeks, but there was no advance. At last out came a withering sun, and the blooms soon fell. About 220 Peaches and Nectarines were formed and grew well to a size as large as a marble, some larger, and then dropped off. I only landed about thirty-five Peaches and Nectarines.

The only tree that held on to perfection all its set fruit was a beautiful Nectarine, Rivers's Pine Apple. It set five fruits. It is quite first-rate, being beautiful and of first-rate flavour. Rivers's Orange Nectarine, the kind gift of Mr. Turner, set three and held on one. That was equally handsome, much larger, and as good. I specially recommend these two Nectarines.

Now, though the result was so small, after so much expense—the sheets, rods, rings, posts, and labour cost £25—still I am not disheartened: the failure was the effect of an extraordinary and abnormal winter and spring. Nothing daunted, I set about managing new wood for next year's crop; and to me there is no pleasure in horticulture so great as the daily supervision and management of my Peach and Nectarine trees.

The country here is so cold that I gave away my two nice Apricot trees, Gros Pêche [Peach Apricot] and St. Ambroise, both good sorts, especially the former. The Apricots here set well, but perish with the cold afterwards.

I will now say something of the way in which my trees are managed. They are pruned alternately, as recommended by Mr. Bréhaut in his excellent work. Some are wholly short-pruned, and have all *bouquets de Mai* attached to the main branches. All the trees here are finely furnished with triple buds; the leaves are off, and the wood looks red and hard. I do not disbud any but the back buds; all the others are left on, and shortened according to judgment. By this means the trees are kept breaking all over, and the plants have lungs at short distances.

Gardeners disbud largely at the time the plants want lungs most—that is, when the sap rises most abundantly; and then by long-pruning, having made their base and centre bare, and having produced gum and canker, they ask in the periodicals, "Why do my fruit trees degenerate?" It is always bad in my opinion, when sap is in activity, to disturb the economy of the tree by large removals of leaves or shoots at one time. I stopped my shoots—not the extensions—on July 12th. On August 12th I cut off half of every leaf, to let in sun and air to harden the wood; and I removed a further portion of each leaf on September 12th. Till fruit is off no leaves should be removed, but only be penned back. Maiden trees I cut to 1 yard high, and train the wood herring-bone fashion. This causes them to bear frequently in the first, and always in the second year. This, of course, depends on the maturation of the wood. Lord Palmerston (two plants), has never been cut down, and next year (its second year), it will bear abundantly.

I will not say a word against orchard houses, heated or otherwise. If they are well managed they are good; but I will not allow that we cannot ordinarily in England grow capital crops of Peaches and Nectarines without them. I like difficulties. I remember what Napoléon I. said—"I delight in danger and difficulties; it is for your kings of Cockaigne to sit at ease." The difficulty of the attempt forms the triumph of the accomplishment.

I differ from many gardeners and amateurs in these two things: I tie with bast instead of using vermin-harbouring shreds, and I keep many sorts instead of a few large ramblers. I allow them only 18 inches of border, remove them frequently with care, and root-prune them. The nails are cast iron; instead of drawing them I either leave them where they are or break them off by a gentle tap. Thus, there are neither shreds nor holes for harbouring insects. I keep down red spiders with a syringe, and sponge with methylated spirits (Mr. Rivers's recommendation) the branches affected with scale, which here is very troublesome. It is instant death to the insects and a very cheap remedy—6*s.* per gallon.

I have just added three of Mr. Rivers's seedlings to my collection—viz., Early Rivers, Magdala, and the Peach Nectarine. The last two are especially fine growers. At present Magdala is the favourite.

I conclude by saying that as many as are thoughtful and wise gained better fruit than Peaches and Nectarines, if they learnt by last year's failures how abortive are all human attempts unless favoured by the Divine blessing.—W. F. Radclyffe, *Okeford Fitzpaine*.

THE NEW GIGANTIC AROID FROM CENTRAL AMERICA.

Our readers will remember that some six weeks since a new gigantic Aroid was exhibited at one of the fortnightly meetings of the Royal Horticultural Society. This extraordinary plant, which has proved to be the sole representative of a new monotypic genus of plants, has been figured in the last number of the "Journal of Botany," where a detailed description may be found from the pen of its discoverer, Dr. Berthold Seemann. It is allied to the genus Dracontium, but differs from that genus in having twice as many stamens as perigonal segments. It produces but a solitary leaf, this one leaf with its petiole being some 14 feet in length. When the leaf has quite died down the flower appears, after the manner of the Colchicum of our meadows, but the flower of this giant Aroid measures 2 feet in length, and 1 foot 8 inches in breadth. The leaf of the one figured attained a height of 7 feet in two months, the leafstalk acquiring a circumference of 9 inches. The same plant ultimately nearly attained the dimensions of the Nicaraguan plants: the leafstalk has a beautifully mottled metallic surface, brimstone yellow in colour, barred and striped with purple, looking, says Dr. Seemann, "like a snake standing bolt upright at the command of some eastern charmer." It was discovered in January of the present year near the Javali Mine, in the Chontales Mountains of Nicaragua, and is altogether the largest Aroid of which we have any knowledge. Its flowers emit the odour peculiar to many Areideæ. The base of the spadix, preserved in spirits in Central America, is now in the herbarium of the British Museum.

Dr. Seemann for several good reasons has named this unique plant *Godwinia gigas*, in honour of one of the Fellows of the Royal Horticultural Society—viz., Mr. George Godwin, F.R.S., F.R.I.B.A., F.S.A., &c., architect, author of "Another Blow for Life," &c., one of the founders of the Art Union of London, and editor of the *Builder*, mainly in recognition of the willing and substantial aid he has so often rendered to literature, science, and art in this country, and for the active support he has given to window gardening in the metropolis, thus helping to spread successfully amongst "even the humbler classes that taste and love for plants, without which, after all, the race of botanists would soon be extinct."

I think a generic name has seldom been better or more deservedly applied than in the dedication of this genus to Mr. Godwin, for his exertions for the benefit and well-being of the people.—W. G. S.

HARDINESS OF PLUMBAGO CAPENSIS.

Of this plant, which is such a special favourite with your correspondent "C. A. G.," I have had some experience, with very little trouble, for the last twenty years.

A large stub on my lawn was furnished with various plants about the year 1850, and among them was Plumbago capensis. Some of the plants were housed for the winter, and some the

winter destroyed; but this little blue flower was allowed to keep its place, and it not only survived, but waxed stronger and stronger each winter, bracing its constitution for the endurance of yet greater chills. For some years past it has had undisputed possession of the stub, completely covering it with its mantle of blue, and forming a strikingly pleasing variety among the reds, whites, and yellows around it. I think the plant may now be considered quite safe, it having stood the test of some very severe winters.—W. J., *Staplehurst, Kent.*

PELARGONIUMS FOR COVERING WALLS.

I see in an answer to a correspondent, in No. 449, that you recommend Pelargonium The Clipper, as suitable for covering a conservatory wall; having grown it in a similar manner, but chiefly for its flowers, I agree with the recommendation, thinking this variety one of the very best for the purpose. In the first batch of the late Mr. Beaton's crosses, sent out by Mr. W. Paul, there are several varieties of sufficient vigour and very distinct in colour, suitable for anyone who may want to plant with the above object. Those which I have grown and can recommend are—Mrs. William Paul, a Nosegay variety with large pink flowers; Amy Hogg, also a Nosegay, with a very large truss and dark rose-coloured flowers; Excellent, rosy scarlet, having a large truss, and good-shaped, thick-petaled flowers; Princess Liechtenstein, salmon pink, and very large. There is another desirable variety called Madame Rudersdorff, which, though more of a salmon colour out of doors, has nearly white flowers in-doors; although it is not of such vigorous growth as the preceding, it is a profuse bloomer. Like all which I have named, it is capable of covering a piece of wall 10 feet high by 6 feet wide, though not in so short a time as the other varieties.

I think for the purpose referred to, this section of the Pelargonium should be more grown because of the quick growth and attractive qualities of the plants, as well as an abundant supply of flowers for cutting being almost a certainty for at least nine months out of the twelve. Their culture, too, is very simple, and unless the plants are mismanaged or neglected they never look unsightly. Mine are growing in a rather heavy, rich, turfy loam, and road drift, with a good sprinkling of charcoal; they have good drainage, manure water at times, and two prunings in the year—namely, in March and August. The pruning chiefly consists in thinning and shortening the shoots. The second pruning gives the plants additional vigour for flowering, which they do all the winter.

With the above Pelargoniums, a plant or two of the lilac-flowered Heliotropium corymbosum may be grown. It flowers the whole of the winter, and most abundantly if treated in a similar manner to the Pelargoniums. With the flowers of the different Pelargoniums I have named, the Heliotrope, and a few sprigs of the Maiden-hair Fern, a bouquet may be made at almost any time, and if the flowers be arranged properly and tastefully it will be fit for any drawing-room.—T. Record.

BUDDING VINES.

Some time since on paying a visit to Trentham, I saw a lot of Vines—Lady Downe's I think—budded with Madresfield Court. Nearly every bud had taken, and they had made fine canes. Though few persons have grafted more Vines than I have had worked here, yet in my ignorance I thought these budded Vines better worth seeing than anything which had come under my observation for a long time, and I set Mr. Stevens down in my mind as a thoroughly clever man. I have seen since an article or two in which the writers make out that there is nothing new in budding Vines, that to them it is quite an old practice; in fact, they and their friends have carried on the practice so extensively, the wonder is how so many of us can have been so behindhand as not to know all about it years ago. Well, it is quite clear Mr. Stevens need not show his Vines to anyone, or, at least, if he do show them, any pride he might have felt in doing so is now quite out of place. The practice, if not as old as the hills, is a very old one. Is it not strange that when anything particularly good and which appears quite new is described, it always is old? I am quite surprised no fossil telegraph posts have been found yet.

Though it is a bad thing to have to confess ignorance, yet it is worse to be unwilling to learn, and I think some of your readers would be glad to know how a young Vine can be cut up into single eyes, and each eye made into a strong fruiting cane, or rather thick rod, in one year. I cannot help thinking that if Mr. Stevens would describe his practice, some of your numerous readers who have not seen the Vines in question, would be much obliged to him for the information.—J. R. Pearson, *Chilwell.*

[We wish Mr. Stevens would oblige us with a detail of his practice. Few persons know how to bud the Vine, although directions were published in 1844.—Eds.]

INDUSTRIAL EMPLOYMENT ASSOCIATION,

ESTABLISHED FOR THE PURPOSE OF PREVENTING PAUPERISM AND CRIME, BY RESCUING DESTITUTE CHILDREN, AND EMPLOYING "WASTE LABOUR ON WASTE LAND." Offices: 35, Parliament Street, S.W.

This Society which has, as our readers will observe, a somewhat long name—yet a shorter one would not, perhaps, properly describe its aim and objects—has recently issued its third report, which is now before us. It takes for its motto, "Prevention is better than cure," and as Lord Stanley has observed, "The principle of the Association is sound;" Lord Shaftesbury, Sir Robert Peel, and others well capable of judging have also written in its favour. At the same time we would warn its promoters not to be too sanguine.

We have at this time a great number of able-bodied workmen leaving our shores, yet we have in the United Kingdom upwards of 31,000,000 acres still uncultivated, some of it capable of high cultivation. These things ought not to be. Then when we consider that children trained to farming operations almost always grow up strong men and women, and capable of earning an honest livelihood, we must regret still more this waste land. Children run to waste for want of employment, land runs to waste for want of cultivation; the former are just fitted to remedy the latter, the latter to remedy the former; and yet this is not done. I wish that the Government would undertake the work. The waste land is England's; the waste children are also England's. This Association endeavours to move both Government and people; we wish it success. We can ourselves speak of the benefit which has arisen from reclaiming land from the dominion of the water; thus Whittlesea Mere was a quarter of a century since a useless portion of England, the land formerly its bed now feeds oxen or grows good corn.

Supposing newly-cultivated land falls into the hands of small holders, much would depend upon their knowledge of cultivating the soil. Thus Fergus O'Connor, when he started his Land Scheme, established a lot of cottages on five-acre plots, near Lincoln. The first occupiers totally failed; they were artisans, and ignorant of soil-culture. Their successors are doing well, being cultivators. One of them is clerk to Rev. Mr. Ellison, he bought one of the five-acre plots, and he and wife and daughter cultivate it. He was a gardener, has a vinery, a Cucumber house, and plant house. He sold £40 worth of plants last year, besides Grapes, &c. It must, however, be observed that the five-acre plots are good land. We are justified in believing that some waste land ought to be brought under good cultivation, and suitable renters could obtain a good livelihood. As in America, so in England, the poorest crowd into the towns; thence come overcrowding, horrible vice, disease, misery extreme, and not seldom crime. If these wasted labourers could be brought to work on now waste land, the tide of human life would be turned back to pure air, clean water, and accommodation fit for beings with mind and souls. Could this Society carry out its object, the happiness and morality of the masses would be increased, and, of course, society itself benefited. The Society has need of funds to continue and strengthen its present staff and labours, and the public must come to its aid, and provide funds of at least £300 a-year for rent of offices and necessary expenses. Those who have to give could surely send a trifle to the Secretary, 35, Parliament Street. Their mite would, perhaps, produce a large interest of good to man.—Wiltshire Rector.

POMOLOGICAL GLEANINGS.

Cherries in the United States.—At the recent meeting of the American Pomological Society at Philadelphia, it was suggested that each delegate should name one variety of Cherry that was considered the best and most flourishing in the section where he resided. This resulted in four of them naming the Kentish, called in the States the Early Richmond, and six Coe's

Transparent, a pale-coloured and rather small Heart Cherry. It seems, therefore, that our large Bigarreau and Heart Cherries do not succeed well either in the eastern or western States. The reports come from Kansas in the west to Massachusets in the east. The cultivators report that the large and choice sorts of Cherries rot on the trees.

—— A few years since if any one had foretold that a good Pine Apple would be sold in London for 2s., and that a large slice would be sold by costermongers for a penny, he would have been laughed at as a visionary. Now, however, the lessons of acclimatisation, and the rapidity of steam vessels, have enabled Mangoes to be sold by our fruiterers. They are raised in Madeira, but are not of the best variety. There are two superior kinds in India, the Small Scarlet and the Malda, the last named having a green outer skin. We were amused the other day at seeing a gentleman attempting to eat one as he would an unpeeled Apple. The proper mode is to remove a part of the outer skin, and scoop out the pulp with a spoon. If the first Mango tasted is well flavoured, the taster will continue to like the fruit; but if the first has a turpentiney flavour, he will never incline to partake of another.

—— Beurré Hardy Pear.—This grand Pear, grand in habit as in fruit, bears well in Scotland. A specimen has been sent to me from near Kelso, where it flourishes as a standard, and is very hardy. It forms a magnificent pyramid, and ought to be planted by the acre. This Pear has been named after Mons. Hardy, formerly of the Luxembourg, a clever pomologist, and English-like in his kind modest bearing.—T. R.

ROYAL HORTICULTURAL SOCIETY.

November 16th.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. Lane & Son, of Berkhampstead, sent three enormous bunches of Muscat of Alexandria Grapes, which had hung since they were ripe in July. The berries were plump and the flavour excellent, though the Muscat flavour was somewhat gone. A special certificate was awarded to them. They also exhibited three handsome bunches of Alicante of large size. Mr. T. Wattam, gardener to T. Longman, Esq., Shendish, Hemel Hempstead, sent three very large bunches of Alicante, well grown and well coloured, which received a special certificate. Mr. Whibley, Mount Pisgah, Sheffield, sent a bunch of Trebbiano and of Chaouch grown in a cool house. Mr. Melville, of Dalmeny Park, sent a small portion of his seedling Perfumed Muscat Grape. The portion sent was too small for the Committee to form any opinion about the size or form of the bunch, but the flavour of the few berries exhibited was very rich and perfumed. Mr. Melville was requested to send a perfect bunch. Mr. R. Fenn, of the Rectory, Woodstock, sent samples of Espiran Grape grown against the wall of a dwelling-house and some from a small vinery, to show the crop from which he had made 342 gallons of wine this season. Mr. Wells, of Southend, sent six bunches of Frankenthal Grapes grown in ground vineries. They were large, and thickly set with well-formed highly coloured berries. They were awarded a special certificate.

Mr. Fowle, gardener to Sir Henry Mildmay, Dogmersfield, sent a basket of large, handsome, and very beautiful Pitmaston Duchesse d'Angoulême Pears, which were awarded a special certificate. Mr. H. Moore, of the Gardens, Bradley Green, near Congleton, sent fruit of a seedling Pear, which was thought very highly of by the Committee, but as the fruit was rather too ripe the Committee were desirous of seeing it again. Mr. G. F. Wilson brought a dish of Triomphe de Jodoigne grown on a pot tree. The fruit were large and handsome, but the flavour was not yet developed, being rather unripe. From the Society's garden came fruit of Beurré du Cercle, Doyenné du Comice, the latter most delicious. Col. Le Couteur, of Jersey, sent dishes of Nouveau Poiteau, Soldat Laboreur, and Crasanne.

Messrs. James Carter & Co., sent leaves of Celery attacked by a disease which proved to be produced by the Puccinia apii. Mr. Charles Turner, of Slough, sent a new Kidney Potato called Beaconsfield, of great excellence. The tubers were cooked, and the Committee unanimously awarded a first-class certificate. Mr. Ingram, gardener to the Duke of Rutland, Belvoir Castle, sent a collection of fine large Potatoes, consisting of Dalmahoy, Ronnd Regent, Paterson's Victoria, Scotch Blue, Long Regent, and Paterson's Economist. The Committee awarded them a special certificate. Mr. Samuel Horley sent a few sticks of Horley's Conqueror Celery, but they were not of sufficient merit to obtain special recommendation. Mr. Lidgard sent a stick of Manchester Solid Red Celery, large, thick, and very solid, which was highly commended. Ocean Pride is a dwarfer variety than the preceding, but not so good in quality, being more of the flavour of Mr. Horley's. Seedling Pink is also a dwarf variety of Red, but inferior in flavour. Horley's Conqueror was also exhibited by Mr. Lidgard, well-grown, but it was much less close and much inferior in flavour to the Manchester Red Solid, which the Committee considered the finest-flavonred of any. Mr. Lidgard was awarded a special certificate.

Mr. Shepherd, gardener to P. Northall Laurie, Esq., Paxhill Park, Sussex, sent a dish of very handsome fruit of Calville Blanche Apple, grown in the open air, to which a special certificate was awarded. Mr. Carmichael, of Sandringham, sent a neat little plant, thickly covered with small, conical, yellow fruit, of a seedling Capsicum. It is evidently a seedling from the West Indian variety called the Scotch Bonnet, has the same flavour, but the plant is dwarfer and would be very useful for decoration. Messrs. Hurst & Son sent a dish of Bedfordshire Champion Onion, which was considered an ordinary sample of Globe Onion.

Mr. Dancer, of Little Sutton, exhibited a large number of cobs of Indian Corn, grown by Mr. Scarrell, of Littlehampton, Sussex, and also by himself. Mr. Scarvell has grown this variety for twenty years, and ripens it every year. Mr. Dancer has grown it for two years, and has always found it ripened well. With such a variety as this, the cobs of which are equal to any we have seen imported from America, there is no reason why Indian Corn may not be grown as a field crop in the warmer soils and early situations in England. It may not be generally known that the London Omnibus Company, since they began to feed their horses on Indian Corn, are saving some thousands of pounds annually. We hope yet to see this variety of Maize become more generally grown.

Messrs. E. G. Henderson & Son sent fruit of Macadamia ternifolia, which was pronounced to be one of the finest-flavoured nuts. This is a new introduction by Messrs. Henderson. The tree is half-hardy, requiring the protection of an orchard house. The nut is the size of those of the North American Walnuts, and much of the same shape, and contains a large solid-fleshed kernel of very rich and excellent flavour.

The Onions exhibited by Col. Le Couteur at the last meeting were cooked and submitted to this meeting, when a special certificate was awarded. Mr. Lovegrove, of Maidenhead, sent two bottles of home-made wine made from Black Hamburgh Grapes grown in the open air. They were both sparkling and of a pink tinge, and were both good sound wines, neither too sweet nor at all acid, and were considered most successful examples of a really wholesome and excellent wine from home-grown fruit. They were awarded a special certificate.

Capt. J. R. Brookes sent a large Gourd grown by the boys at Feltham Industrial Schools, weighing 124 lbs. It was awarded a special certificate. M. E. Treeve, Esq., exhibited a large Gourd grown in a small back garden in Edwardes Square, Kensington, which weighed 60 lbs.

Floral Committee.—Rev. J. Dix in the chair. Mr. Perkins, of Lymington, sent two seedling Primula sinensis with double flowers, young plants of Fire King Tricolor Pelargonium, and cut flowers of Prince of Orange Picotee. Messrs. Veitch sent a fine collection of Orchids, among them a remarkably fine specimen of Oncidium Rogersii, which had previously received a first-class certificate; Oncidium cnranthenm, with bright yellow flowers, which was awarded a first-class certificate; Cycnoches musciferum, Miltonia Moreliana, Thrinax elegans, and Primula sinensis variegata. A special certificate was awarded for the group. Mr. Bull sent Litobrochia umbellats, which received a first-class certificate; this very fine Fern had previously received a second-class certificate. Mr. Bull also sent Dicksonia Youngii (squarrosa ?); Dracæna Guilfoylei, a promising plant, which it was requested should be shown again; and Oncidium ramiferum. The collection of plants received a special certificate. Mr. Rowe, gardener to Mrs. Lewis, Roehampton, sent six Primula sinensis, too early for their merits to be decided on.

Messrs. Downie, Laird, & Laing exhibited a collection of Zonal Pelargoniums, for which a special certificate was awarded. This is not the season to form any just idea of this class of plants with regard to colour, &c.—a special certificate was awarded. Messrs. Lee, of Hammersmith, sent Laurus camelliæfolius, a very bad-foliaged Laurel. Mr. Linden, of Brussels, exhibited a small collection of Orchids. Maxillaria splendens, very much like a Lycaste, received a first-class certificate. He had also Stenia fimbriata, and others. A first-class was awarded. Mr. Green, gardener to W. Wilson Saunders, Esq., had a Myrsiphyllum, and Siphocampylus bulgens (Humboldtii ?), which received a first-class certificate. Mr. Jacques, gardener to P. Cunliffe, Esq., Croydon, sent a species of Sarcanthus. Mr. Williams contributed a collection of beautiful Orchids, and received a special certificate. Among them were Maxillaria nigrescens, Oncidium xanthodon, and Masdevallia candida. Mr. Wilson, gardener to W. Marshall, Esq., sent a beautiful specimen of Sarcanthus bigibbus, which was awarded a first-class certificate. Mr. Turner, of Slough, sent Tropæolum Ochroleucum, still maintaining its good character, and Tricolor Pelargonium Mrs. Hally. Major R. Trevor Clarke sent two hybrid Pelargoniums, which were generally thought to be in a retrograde position.

Dahlia imperialis, from Chiswick, was worthily awarded a first-class certificate. Branches of this superb plant were exhibited in pots, and were generally admired. Messrs. Henderson sent eight Japanese Chrysanthemums, and Messrs. Salter a seedling Japanese Chrysanthemum The Sultan, a noble deep rose flower, which was awarded a first-class certificate.

On this occasion prizes were offered by W. Wilson Saunders, Esq., for the best collection of winter bedding plants in pots or boxes. There was only one collection shown, that from Messrs. Standish and Co., of the Royal Nurseries, Ascot, who took the first prize. Their

collection was extensive and fine, and very neatly arranged in circular groups rising from each end to the centre, with larger specimens placed between the groups, the margins to the latter chiefly consisting of plants with variegated foliage. The centre was a group of Hollies, a variegated plant covered with berries occupying the middle, and this was surrounded by dark-leaved kinds, and then by dwarf golden-variegated Hollies. Among the plants shown were Osmanthus ilicifolius and the dwarf variegated kind; green-leaved Aucubas, surrounded by the white-variegated Euonymus japonicus latifolius, an extremely hardy plant, having withstood a temperature of 40° below freezing without injury; Abies Lowii; Podocarpus coriacea; Aralia Sieboldii, surrounded by Yucca filamentosa, and the variegated Bamboo; Juniperus japonica albo-variegata, with finely variegated glaucous foliage; Cupressus Lawsoniana compacta; Ilex balearica hybrida, a handsome dark-leaved Holly; Retinospora obtusa, one of the hardiest plants ever introduced from Japan, and a variety of it called nana gracilis, a pretty plant for small gardens; Taxus coriacea, which stands the winter at Flushing, while the common Yew is injured; Cryptomeria elegans, and Thujopsis dolabrata, both extremely hardy; Thujopsis ketevirens; and a group of seedling Aucubas, with grafted standards interspersed, the berries for the most part not yet coloured; but a great recommendation of the berry-bearing Aucubas is, that their fruit remains beautiful for several months. Ligustrum coriaceum, which was also shown, deserves especial notice on account of its thick shining leaves, which render it very suitable for cultivation in London, as the soot can be easily washed off. An Abies, provisionally named Abies japonica, is remarkable for its rapid growth, plants in 3-inch pots this spring having by this time made a growth of upwards of 2 feet. Messrs. Standish had, besides, in their collection numerous other fine sorts of Conifers belonging to the Abies, Cupressus, Juniperus, and Retinospora families.

Prizes were also offered by the Society. These in Class 2 were for four large-flowered Chrysanthemums in pots. The first prize went to Mr. James, gardener to W. F. Watson, Esq., Isleworth, for plants grown in the shape of inverted cones, and consisting of Lady Talfourd with fifteen blooms, Mrs. G. Rundle with seventeen, Jardin des Plantes with thirteen, and Empress of India with ten. The blooms were large and fine, especially considering the number allowed to each plant. Mr. Rowe, gardener to Mrs. Lewis, Roehampton, was second with a splendid specimen of Prince of Wales, Lady Harding, Alma, very fine, and Golden Christine, all plants of large size and admirably bloomed. Mr. Forsyth was third.

Class 3 was for Pompons, and the first prize was taken by Mr. Forsyth with excellent specimens of Bob, Andromeda, Sainte Thais, and Golden Aurore; Mr. Rowe being second with very large specimens of the Anemone-flowered kinds Miss Nightingale, Mr. Astie, Marguerite de Wildemar, and Antonius.

Class 4 was for twelve cut blooms, nurserymen. In this Mr. Forsyth was first with Princess of Teck, Isabella Bott, General Slade, Princess Beatrice, Mrs. Heale, John Salter, Princess of Wales, Oliver Cromwell, Lady Harding, Rev. J. Dix, &c.

Class 5 was for the best six blooms. Here Mr. Rowe was first with very fine examples of Queen of England, John Salter, Lady Harding, Empress of India, and Jardin des Plantes. Mr. Douglas, Loxford Hall, was second with fine blooms of Mrs. G. Rundle, Prince Alfred, Her Majesty, Rifleman, Princess of Teck, and Prince Alfred. Mr. Berry, Roehampton, was third. Several other good stands were exhibited, and Mr. Rowe sent a fine stand of twenty-four, for which he received a special certificate.

Class 6 was for twelve plants bearing decorative fruit, and of these there was only one exhibitor, Mr. Bull, who had a first prize for well-fruited plants of Rivina lævis, Ardisia crenulata, Skimmia japonica, and varieties of Solanum capsicastrum.

General Meeting.—W. Wilson Saunders, Esq., F.R.S., in the chair. After the election of five new Fellows, and the usual announcement of awards, the Rev. M. J. Berkeley said that on examining Bonvardia jasminiflora, shown at a previous meeting, with specimens at Kew, it proved to be only a variety of B. longiflora; also that a Gongora from the Bishop of Winchester was Gongora bufonia of the "Botanical Register." Mr. Berkeley then made some remarks on Picea cephalonica and P. Pinsapo, by which it appeared that the latter might not be a true species after all, but further evidence on this point, as furnished by specimens from Spain and Africa, was considered desirable. Macadamia ternifolia, noticed in our Fruit Committee report, was next mentioned, as well as the branches of the magnificent Dahlia imperialis from Chiswick, where the plant grew as much as 12 or 14 feet high, but would not flower unless placed in a warmer temperature than that of the orchard house. The tubers were brought from Cannes by Mr. Bateman. The flowers had been exhibited last December, but not in such perfection as on the present occasion. As regards the pretty blue-flowered Coleus barbatus, from Chiswick, it was there named Coleus lanuginosus, but the latter is far more woolly than C. barbatus, which extends from India to Abyssinia. Messrs. Standish's collection of winter plants was then mentioned as being most praiseworthy, and the hardiness of some of the species it contained referred to.

The Chairman said that the collection just mentioned was, indeed, a noble one. When he cleared his beds out of doors of their summer occupants, he filled them with evergreens, which produce a charming effect. These plants should be potted when young, and never allowed to become pot-bound; then when autumn came the pots should be plunged, or, instead of plunging, after arranging the plants Brake Fern might be pushed in among the pots, and would form a brown fringe round the outside. The tallest plants should be placed in the centre, the shorter at the outsides, and the colours of the foliage could be varied, and Hollies, Skimmias, and other berried plants would give a further variety. Thus a pretty winter garden might easily be made. With regard to a Siphocampylus shown by himself as S. fulgens, he saw its name had been changed to S. Humboldtii, but the former was that under which he had received it. Referring then to Dahlia imperialis, he had had it a year, and it grew with him to a great height, and had to be extended along the house; but he believed it could be made to flower at a much lower height by grafting. The Myrsiphyllum, from his own garden, was pointed out as a most elegant plant at night, though exhibiting no great beauty by day; also Oncidium Rogersii, one of the most graceful of the Oncidiums, and as well worthy of cultivation as any.

The proceedings then closed with the announcement that the next meeting will be held December 21st.

GROWING CELERY IN BEDS.

Having, as "J. T." described it (see page 379), a large family to supply out of a small garden, I last year adopted the bed system, and as an experiment I planted one bed with five rows, and one with four. The result was very satisfactory, but the bed with four rows was decidedly the better, so this year I have planted both beds with four rows in each. I used the Celery from the bed with five rows first, as I certainly found it did not keep so well as the other. The sorts I grew last year were Ivery's Nonsuch, pink, which I consider the best variety for general use as, though it does not grow so large as some kinds, it has an excellent flavour. Cole's Defiance Red, also proved an excellent Celery with me, and it keeps better than Ivery's. I grew the same this year with the addition of Matchless, which seems very solid, but I have not used it at present, so cannot say much about it.

In April, I make beds 4 feet 6 inches wide, throwing out the soil to the depth of 18 inches, and as I have no convenience for hardening-off bedding plants, of which I this year planted out 2700, I rake and level the beds, placing a little soot or lime at the bottom to keep worms from entering the pots. I then put the bedding plants in, covering up at night with deal shutters which I take off the Vine borders, and this protection has answered very well. As soon as the bedding plants are taken out, I dig-in about 12 inches of manure, planting the Celery 12 inches apart in the rows, and 10 inches from row to row, care being taken to keep the plants in line, otherwise they are difficult to earth-up.

The Celery is well watered all the summer, the surface soil well stirred, the weeds kept down, and particular attention paid to removing the suckers. I find it is better to tie the plants up loosely a fortnight before earthing, which I do at the end of August. I then earth-up the half of one bed quite to the leaves, ready to be used in the first week of October. The other half I only partly earth-up, and finish earthing in September. The other bed which I require for late use is only earthed-up 9 inches, as I prefer stable litter well packed round and among the tops, as while it blanches it, the litter prevents damping.

I may add my kitchen garden lies very low, being on the bog, and though I have drained it thoroughly, it is naturally damp. I must also state that for very early use I grow a single row of white and one of red to save the beds. I cannot account for the three inside rows doing so badly with "J. T.," mine being as nearly alike as they can be, and as yet I have not had a bad stalk this season, but I should think much depends on the aspect of the beds; my beds run from east to west, but in a wet heavy soil I should alter their direction. I write these notes merely to show that good Celery may be grown in beds, though I believe I am the only one who grows it so in this neighbourhood, and during the summer I am frequently asked how to earth it up.—Stephen Castle, *Gardener to James McConnel, Esq., Bent Hill, Prestwich.*

CHRYSANTHEMUMS AT Messrs. SALTER & SON'S, VERSAILLES NURSERY, HAMMERSMITH.

When a flower has attained such perfection of form as the incurved varieties of the Chrysanthemum now exhibit, when almost every possible colour is represented, when it would seem that size can go no further, it is evident that progress

must be very difficult, but that it is not impossible the grand display of Chrysanthemums at the Versailles Nursery affords abundant proofs. Year by year it improves, and the improvement being so constant, it has become almost a needless repetition to mention the fact; but this autumn, in the number, size, and quality of the blooms, and in the arrangement of the plants producing them and of those employed as adjuncts, Messrs. Salter's exhibition is far in advance of that of any previous year. It is a splendid sight which no one interested in the Chrysanthemum should miss, whether his object be to see the best of the kinds already sent out or to form an estimate of those which are to come, and of which Messrs. Salter's nursery is the head-quarters.

Taking the flowers already in the hands of the public first, the best at present in bloom are :—

White and Pale Blush.—White Beverley; Rotundiflorum, a beautiful new variety of this year, a sport from Golden Beverley, delicate blush changing to pale lilac, and almost globular in form; Princess of Teck, fine, very pale blush; Mrs. G. Rundle; Virgin Queen; Novelty; Fleur de Marie, a beautiful Anemone-flowered kind, quite 4 inches in diameter; and Beauty, blush, nearly white.

Shades of Rose-colour.—Princess of Wales, Lady Hardiog, Princese Beatrice, Plenipo, sent out in the spring of thie year, rosy lilac; Lady Talfourd, not large, but forming beautiful specimen plants, and when well grown furnishing fine cut blooms; Compactum; Finette, a beautiful lilac peach Anemone-flowered variety of this year, delicate in colour, and dwarf in habit; Pink Perfection, also new this year, very large and beautiful both in form and colour; Bella Donna; Themis; Lady Slade; Prince Alfred; Fingal, magnificent, the blooms 5 inches in diameter, and the florets an inch in breadth—this Mr. Salter considers the grandest flower ever raised; and Christine, beautiful for specimens and conservatory decoration.

Crimson, Claret, and Purple.—Prince of Wales, Lord Clyde, crimson with bright tips, splendid for conservatory specimens; Sanguineum, as yet hardly out, but a finely incurved very showy kind, especially when grown for specimen plants; Julie Lagravère, dark velvety crimson, splendid in colour and very effective as a specimen plant; Ossian, very large; Prince Albert, reflexed, fine for specimens; Mr. Wyness, beautiful mulberry colour; Captivation, purple, with a white bottom; Progne, splendid in colour, late-blooming, and very effective, though the flowers are rather small; Hercules, very large; Josiah Wedgwood; and Purpureum elegans, darker in colour than Progne, and, like it, brilliant when grown as a specimen plant.

Yellow and Orange.—Golden Beverley; Iona; Jardin des Plantes; Guernsey Nugget, beautiful pale yellow; Golden John Salter, new this year, a sport from John Salter, rich in colour; Bronze Jardin des Plantes; Aureum multiflorum; Etoile Polaire; Orange Annie Salter, new this year, a fine sport of Annie Salter.

Orange and Brown.—Little Harry, not large but beautifully incurved; Bernard Palissy, Rev. J. Dix, Beethoven, new this year, with broad finely-incurved florets, bronzed red, tipped with yellow; John Salter; General Slade; Golden Eagle; and Dr. Brock.

The novelties to be sent out during the next spring always constitute a most interesting portion of the display at Messrs. Salter's, and of these there is no lack this year, while there are others which will only show themselves later in the season. Among those at present in bloom are the following—viz., Duke of Edinburgh, very large, finely incurved, rosy lilac with a lighter centre; Norma, not large, but a very pretty, ivory-white kind, of compact habit; Miss Hope, medium-sized, lilac, with a lighter centre; Ondine, medium-sized, cream-coloured and lilac, with a buff centre, and promising to be finely incurved; Princess Louise, Anemone-flowered, pale blush with a high lilac centre; Mrs. Wreford Major, deep pencilled rose-colour, of compact habit, and likely to form a fine conservatory plant; and Marginata, a fine Anemone-flowered kind, blush, with the "guard petals," or outer row of florets, edged with rosy lilac. This Mr. Salter thinks will give rise to a new strain. Besides the foregoing, there are several others very promising, but not sufficiently expanded to show what they will be.

The Japanese Chrysanthemums are of themselves a great attraction, being so distinct and varied in their forms, and some of them so effective for conservatory decoration. The novelties among these are The Sultan, resembling The Daimio in its general character, but of a more rosy colour, very free-flowering, and, like the variety just named, highly ornamental as a conservatory plant; Aurora, also with ribbon-like florets, bright orange; Emperor of China, quilled, waxy blush, with the centre rose-coloured mingled with yellow; Viceroy of Egypt, deep rosy purple with a white back, and, as with the preceding, the first row of florets is quilled, and the rest flattened and curled inwards towards the tip; Chinoise, bright red, tipped with yellow, very distinct, and likely to be an acquisition; Chang, very large, with broad twisted florets, dull red, with a yellow back; Giant, quilled, pale lilac, so large that when spread out Mr. Salter assures us the flowers measure nearly a foot in diameter; and Gold Thread, also quilled, golden amber, and the leaves of the plant have likewise a well-marked golden tinge, especially in summer. Negro, splendid in colour, dark maroon; and Mandarin, with yellow ribbon-like florets, are the remainder of the named kinds, but there are several more coming on, and among them a large unnamed kind with jagged white and sulphur-coloured florets.

Of the Japanese varieties already sent out, The Daimio, Red Dragon, Hero of Magdala, tasselled, Indian red with a yellow back; Comet, reddish orange with a yellow back; Aimée Naurel, white, with rosy lines; Meteor; James Salter; Morgiana, with broad red florets backed with yellow; Regalia; and Dr. Masters, may be mentioned as well worthy of attention.

In addition to the Chrysanthemums there is an interesting collection of Sedums, Sempervivums, and other succulent plants, several of which are either new or rare. Among these may be mentioned Echeveria pulverulenta, with the leaves having a beautifully powdered appearance; E. agavoides, like a little Aloe; Cotyledon fasciularis; Agave Verscheffelti obovata; Rhipsalis prismatica; Sempervivum glutinosum, &c.

At the entrance of the house is an undulated bank beautifully carpeted with Mentha corsica, Saxifraga hypnoides minor, Sedum sexangulare, and Sedum glaucum; and the opposite corner is filled with an elegant mosaic design executed with these plants, Echeverias metallica, sanguinea, and glauca, and Pachyphiton bracteosum, the whole being backed with Adiantum cuneatum, the showy Chilian Beet, Centaurea candidissima, and Isolepis gracilis.

Next to the Chrysanthemums, the most interesting object in the house is the new Dahlia imperialis, which Messrs. Salter grew last year but without flowering it, although the plant became much too tall for the house. This year Mr. Alfred Salter grafted a shoot of it on a tuber of one of the lilliputian varieties, and the results have been a considerable diminution in height, the plant from the grafted tuber being only about 8 feet high, instead of more than 12 feet as at Chiswick, and an alteration of habit as well; for, while the ungrafted plant, of which there is also one in the house, makes a long bare stem, the leaves dropping off as the height increases, the plant from the grafted tuber is branched all the way up the stem. Although the flower buds are formed, these have not expanded, and additional heat will probably be necessary before they do so.

NOTES AND GLEANINGS.

All our readers will be gratified by knowing that Dr. J. D. Hooker, Director of the Kew Gardens, has had conferred upon him a Civil Companionship of the Order of the Bath.

—— The Country Meeting of The Royal Horticultural Society proposed to be held next year at Oxford, simultaneously with the Royal Agricultural Society's Meeting, is well supported by the Oxonians. We also understand that the Council of the Society have resolved on issuing a bronze medal to be called the "Rare Plant Medal," and to be awarded at any of the Society's Meetings for the first exhibition in this country of plants of great botanical interest.

—— In the Annual Report of the Royal Botanic Society, Regent's Park, recently issued, it is stated that during last season free orders of admission to the gardens for the purpose of study have been granted to two hundred students and artists, and 10,653 specimens of plants have been given to professors and lecturers at the principal hospitals and schools of art and medicine. The collection of living economic plants now contains specimens of all the spices and condiments in domestic use, most of the tropical esculent fruits, and many of those from which furniture and other woods are obtained, the principal gums and medicinal products, and the poison trees of Brazil and Madagascar. The lecturers at the schools of medicine attached to the various metropolitan hospitals are greatly indebted to the liberality of the Botanic Gardens in furnishing

them with a copious supply of fresh specimens, so difficult to obtain in London, and without which the lectures would lose so much of their instruction. We may suggest, however, whether some improvements might not be introduced into the so-called "herbaceous" department of the Gardens. A needless amount of space appears to be occupied by the arrangement of British plants in two different classifications, the Natural and the Linnæan, the latter being now entirely abandoned by all teachers of botany. Sufficient care also is not taken that the labels should correspond to the plants really growing beside them. It is confusing to the student to find immediately in front of a label a plant growing in full luxuriance belonging to an entirely different family, which has accidentally strayed there, and has not been weeded out. At Kew this department is kept in much better order. The Royal Botanic Society are now soliciting contributions in aid of the extensions of their magnificent winter garden.—(*Nature*, a new weekly journal of science, published by Macmillan & Co.).

WORK FOR THE WEEK.

KITCHEN GARDEN.

While the weather remains favourable continue to dig and trench the ground throughout this department, that the air may permeate the soil and keep it in a healthy condition for succeeding crops; it is also the best known means for the destruction of insects and their larvæ. Take every favourable opportunity for hoeing, forking, and ridge-trenching. It is not those who apply the greatest quantity of manure to the soil who are always enabled to produce the most abundant crops; it is the judicious application of it that will insure the greatest success. *Cabbage*, earth-up those planted for Coleworts in winter and early in spring, and look over the principal plantations frequently to see if slugs attack the plants; if such depredators are numerous lay a quantity of Cabbage leaves on the ground, and examine them daily. A pail of hot water or some lime may be taken round at the time the plants are examined, and the slugs shaken into it. Many thousands of these depredators may thus be destroyed at this time of year. *Cauliflowers*, lose no time in taking up those nearly fit for use; lay them in a frame so as not to touch each other, and keep them free from dead and rotten leaves. *Celery*, as soon as the soil becomes a little dry, earth-up that intended for winter use to a good height; it will be necessary to attend to this as early as an opportunity offers, as the frost may set in shortly and cause much injury, as the weather has prevented earthing-up lately. *Endive*, continue to blanch it by tying up or by wrapping the leaves together, and laying two flat tiles on each plant, so as to form a ridge, one overlapping the other. *Lettuce*, pay the same attention to the autumn plantations that was recommended for the Cabbages. Give air daily to the young plants in frames. Cabbage Lettuces in frames for winter use will not require much air. *Peas* and *Beans*, a few may be sown on a dry and warm border. Some gardeners cover them with cinder ashes, but this is a bad practice. I have several times seen them go off in the spring, and have been fully satisfied the ashes were the cause of their so doing. *Shallots* and *Garlic* should be planted as early as possible.

FRUIT GARDEN.

The weather being now favourable, the planting of all sorts of fruit trees should be proceeded with as rapidly as possible; it is of great importance to plant them as early in the month as possible. Prune and nail Pears, Plums, Cherries, Apples, Gooseberries, Currants, &c; unnail the young shoots of Peach and Nectarine trees; prune and tie espalier trees as soon as the leaves fall, and prepare ground for Gooseberry and Currant bushes and new Raspberry plantations.

FLOWER GARDEN.

The beds being now filled with spring-flowering plants, a regular cleaning-up of grass and gravel walks should take place, in order that the whole may have a neat appearance during the winter. If the walks are much soiled a surfacing of fresh gravel should be spread over the principal ones in connection with the flower garden, so as to preserve a fresh and neat appearance. The stock of cuttings and newly-potted plants will require care to prevent them from damping off; a good plan is to raise the sashes at the back and front, and to let them remain in that condition. As the weather may change suddenly, be prepared with plenty of covering material for use when wanted. If any Hyacinths or Tulips yet remain unplanted, planting should not be delayed. Crocuses and other hardy bulbs should also be planted. The removal and planting of shrubs and trees should now engage the attention of those who have it to do, and all alterations should be proceeded with as fast as the weather and other circumstances will permit. It is far less expensive to have any alterations that are to be made done quickly, than to have them done at what is called leisure time. All tender or half-hardy shrubs should have some protection prepared forthwith, and especially the tender kinds of Roses. Standards of the latter may have a bunch of dry moss, or a wisp of hay or straw, or some dried fern bound round the head, and the whole well fastened to a stake. Roses in beds, according to Mr. Rivers, and others, are best with a coating of moss. Any porous material which will not hold water long, and, of course, permit the air to circulate, will no doubt answer. The ground should be coated over 4 inches thick at least. From the fine growing weather during the past autumn, Pinks have become well established, and, generally speaking, are looking as fine and healthy as the most enthusiastic cultivator could desire. They will want but little protection during the winter, except from rabbits. Tulips may now be considered safe if planted, though the careful grower, and those who have valuable collections, will make preparations, by roofing the beds, and having mats sewed together, for covering in very severe frost. Polyanthuses are very liable to the attacks of mice during frosty weather, and they will speedily devour the hearts of the plants; their visits must be stopped by any method most convenient, and phosphoric poison is, perhaps, the safest and best method of destruction. Too little importance is, in general, attached to mulching and top-dressing, for whether we consider the utility of shutting-in, or rather arresting the departure of the remaining ground heat of the past summer, or adding nutritious principles to the soil for the ensuing year, the operation is one not to be neglected. It ought to be well considered that the soil has no heat to gain between this period and the end of February, but, on the contrary, a progressive loss must ensue for the next two months at least, until we resort to the practice of mulching. With all newly-planted trees or shrubs intended for choice specimens, or for immediate effect, this proceeding is indispensable, as connected with early autumn planting, whilst for Vine borders, whether the Vines are intended to be forced early, or are only to bear very late Grapes, the practice is equally necessary and important.

GREENHOUSE AND CONSERVATORY.

The stock of plants to bloom at Christmas, consisting partly of stove plants grown for the purpose, and partly of forced shrubs and bulbs, should now receive some attention, particularly the latter, which should be undergoing a slight amount of forcing to bloom them at that time. Choice Azaleas and Oranges may be assisted by a little additional heat, being careful, however, to apply it gradually. At the same time, if there is a forcing house, a portion of the stock of Roses, Lilacs, Syringas, Deutzias, and other hardy shrubs from the reserve pit, may be placed in the cool end, or in a light situation in an early vinery or Peach house: if they can be afforded a slight bottom heat all the better. A few of the most easily forced American plants, including some of the earliest-flowering Rhododendrons, should be added. Bring forward Hyacinths, and early Tulips, in gentle bottom heat. Double Roman Narcissuses, Crocuses, Neapolitan Violets, Mignonette, and Cyclamens, bloom early without much forcing, and answer best placed on shelves at the back of vineries, to catch every ray of light, and to insure them from damp.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

With two or three nights of sharp frost *protection* was one of the chief matters to be thought about. Dry litter is very good for the purpose; rough hay is better, it is so light and clean. We have some that, but for its being well supplied with bits of little sticks and hard dried leaves of Holly and Evergreen Oak, would be too good for the purpose. However, we should not like to exchange it except for its equivalent in value of the best straw. A little stack of this hay, collected from parts of the pleasure ground not seen much, and the grass allowed to grow long before being cut for the first time, makes us tolerably independent when a severe frost comes on us suddenly. A little shaken lightly over glass or over growing crops out of doors, greatly protects from the keenness of the frost, and when fire heat is used a little protection over glass renders hard firing and its evils unnecessary. Fern collected when light and dry is also an excellent protection, but it is not quite so handy, and

is sooner worn out than rough hay. Could we only keep the latter dry it would last a long time, but it soon loses most of its value when several times wetted. Though people are quite well aware of this, there seems to be a natural tendency to leave all such coverings in front of frames and pits, where, if heavy rains come, it will not only have its own share of wet, but also that which runs off the glass. It is easy to place it safely in little heaps, where it would be mostly free from both contingencies.

We had everything so well secured, that we were almost sorry when the mild change came. We had so much in hand, that if the frost continued we had resolved to let a good many things where there was no artificial heat remain covered up, but we could not do so when a mildness like that of April returned, making a difference in two days of little less than 30° Fahrenheit. The covering-up among vegetables had chiefly reference to Cauliflower, forward Broccoli, Celery, and blanched Endive and Lettuce. Some outside work has prevented us doing much in the kitchen garden, except wheeling some decayed hotbed manure into heaps, whence we can take it easily to places at hand as wanted. Radishes that received a little protection are still nice and crisp.

In the first piece in the Mushroom house, spawned between five and six weeks, there are some white points appearing, the harbingers of what we hope will be a good gathering. We mentioned that a fortnight or so after spawning and earthing-up, this bed seemed to be rather cold, and as it was on a broad shelf some barrowloads of hot droppings were placed in the then open space beneath, which had the desired effect of bringing heat into the bed, until we had reason to believe the spawn was working, which always makes heat as it progresses. We have just spawned and firmly beaten a third piece, and put in some dung for a small fourth piece, as we find it is best in every way, and especially as suiting our resources, to do only a little piece at a time, and to follow on continuously. We covered more thickly the bed in the open shed, still producing pretty freely, the last piece only a little in advance of the first piece in the Mushroom house. In this boisterous and frosty weather, however, we have drawn some Laurel branches through some old hurdles, rough-wattling them, and set them along the front of the shed, which keeps the air stiller inside than when open, and yet allows the air to sift through.

Celery in Beds.—The covering over these, even in severe frost, ought to be light, or it will break down the leafstalks and thus encourage them to rot. We notice what an observing correspondent says at page 378. We think his beds were quite deep enough and rich enough. We have some with four and five plants across, but we prefer three plants in general, and also dwarf kinds instead of very tall ones. We are using red Celery now, referred to lately as an Irish kind. A length of fully 18 inches of it is fit for table, and the centre row is as good as the outside ones. The beds of Incomparable are as equal as possible plant for plant, and last season we did not lose more than one or two plants from damping or otherwise. Of course, according to the vigour of the plant they demand room, generally from 12 to 15 inches from each other across the bed. For late Celery some trouble is needed in the earthing-up, such as using ashes round the plant, and a little litter at the last when it can be obtained. For late Celery, also, it is as well not to have a deep trench. We are so sure that the plan is a good one for all, and especially for small gardens, that we have no doubt our correspondent will be able to speak more highly of the bedding system next season.

Decaying, spotting, and bolting Celery is not confined to that grown in beds. We know of a case where more than half the plants fit for use have shown their flower stalks, and yet it is said they were supplied plentifully with water after being planted. We fear they had been starved and dried previously. We hear of another case where the plants, though looking healthy outside, are all, or nearly all, spotting, rusting, or rotting at the core. They were well supplied with manure water, and we could just be less sure than if we had seen the water applied that the water, instead of being carefully poured over the soil, was poured on the plants and soil rather indiscriminately. We can hardly venture on manure water being so applied in our absence, unless it be followed with clean water over the foliage.

Chiefly as a saving of labour in out-door watering, and much in-door watering likewise, we use the spout of the pot, and that does admirably, if the workman will stoop sufficiently to allow the spout nearly to reach the ground; but it is a very different affair when, standing nearly upright, as, if not noticed, he will be almost sure to do, and holding the watercan well up, he pours out a jet, as if he felt a pleasure in contemplating the miniature cascade. The roots and collars of plants, not to speak of the tender centres of such plants as Celery, are often thus greatly injured, because a man, when he knows the right way, will take the wrong. In our course through life, the errors we commit are in general less chargeable to ignorance than to the simple fact that though we knew what was right, we did not do it.

FRUIT GARDEN.

We have not finished washing and tying the trees on the back of our Peach house, as the only wet day we had we appropriated to potting and mending metal hand-lights. Cutting glass for so many corner pieces at the top is a tedious affair. Were we purchasing for ourselves we would never trouble with such glasses, as they are expensive at first, and seem to offer a temptation to every iron-pointed boot to try conclusions with them. Small, rough, wooden boxes, 2 feet square, with a glazed top, would be far preferable if made like a little frame with the top moveable, and so that either side would do uppermost.

The Peach house would have been finished but for the fact that when done we could not store more than a row of boxes in it next the back wall, every other part being filled with bedding plants, and there they will remain until the Peach trees are started, and the most of the Grapes in the late house are cut.

Strawberry Plants in Pots.—We mentioned lately our having turned these on their sides to keep the soil from being saturated. This would have rendered them more liable still to injury from the frosts of the middle of the week, but a sprinkling of litter all over kept them quite safe. Very little protection thus suffices for plants placed on the ground. We have found Pelargoniums pulled out of the beds, and laid on the ground in an open place, when thus protected, perfectly fresh and sound a month after their neighbours were a mass of decay. We turned out some of these Strawberry plants on the 13th inst., the covering being removed on the previous day, and we never saw pots better filled with fine, large, light-coloured roots. An earth pit that had late Kidney Beans, being now at liberty, and having some dry tree leaves, we spread a little dry ashes over the surface of the earth pit, and filled it with Strawberry pots, resting their bases on the ashes as a security against worms, and packed them in the tree leaves as closely to each other as they would go, allowing a few leaves to rest on the surface of the pot, and leaving all the rather green leaves belonging to the plants themselves; for though the pots have long been crammed with roots, and no watering has been given for a long time, the leaves are greener than we like to see them now. These we shall cover with old sashes condemned twenty years ago, but, with a little patching on a wet day, still very useful for such rough work, the sashes merely resting on the back and front of the earth pit. Some of the sides of these sashes that for more than twenty years have not had a touch of paint, are as sound and firm as the day they were cut from a deal log or batten. Of course, after such rough treatment, covered over often with damp litter, no rafters to stay them, &c., some are going and rotting.

We could not wish for a safer elysium of rest for our Strawberry plants in pots, until we wished to excite them into fresh growth, and a covering of strained calico would be second best, both good as throwing off heavy rains, the few leaves on the surface of the soil, and the foliage of the plants, affording good protection from frost, if the vermin would only let them alone. We shall be obliged to look at them every day, for mice and rats, not to speak of larger four-footed enemies, would soon make wrecks of the crowns. To keep all these destroyers at bay, we have placed a band of tar round the pit, and set traps and baits at no great distance.

We shall most likely have to store the rest in a similar place, or in the orchard house. We greatly prefer the latter, as the mice, &c., seldom trouble them there, and the first attack is easily seen, but the room there is nearly filled up already. Some years ago, in a very severe frost, we had a similar earth pit to that referred to, protected with a little litter for the best part of a week, and on uncovering we found nearly one-third of our plants, and the best of them, too, useless, from the hearts being eaten out of them.

We hope to be excused dwelling on these simple matters, as we believe more than half the failures as respects Strawberries in pots are owing to carelessness as to the condition of the plants in winter. If plunged and waterlogged out of doors, the

roots become dropsical, and the flower-bud is apt to decay. If the pots stand unprotected, the roots are apt to be ruptured or killed, and the buds injured, by frost. If the pots are built on their sides in conical stacks, they can easily be protected from frost and wet, and yet have access to light and air; but a neglect in one very cold night may injure them severely, and if the winter is bracing and dry, the soil is apt to become too dry, and buds and roots would then suffer. Where glass frames or calico can be had to throw off the wet, they will be best. Even in cold orchard houses and frames, with plenty of air and no rain, care must be taken that the soil do not become dry, otherwise the buds and roots will suffer. Just now it is well to have the plants dry rather than wet, to arrest growth, and concentrate the powers of fruiting; but until we commence forcing, the plants should not suffer from dryness.
